Abstract

This work advances a relational physics that begins not with spacetime but with a fibred continuum ($\mathcal{C}_d$) of primordial quantum singularities ($\mathfrak{B}_{\vec{r}}$) animated by a quantum holo-state, Holo-State $|\overset{\circ}{\mathbf{\Psi}}\rangle$,

$$\mathcal{C}_d := \left\{\mathfrak{B}_{\vec{r}},\ \hat{\Omega}_{\vec{r}},\ \mathfrak{F}_{\vec{x}}\right\}_{\vec{x}\in\mathcal{C}_d}.$$

Reality is scaffolded by a triadic distance and time *relational phase-geometry bundle* ($\pi : \mathfrak{F} \to \mathcal{X}_q$) with fibres ($\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \times \mathcal{F}_x^{\text{time}}$), so separation and duration are read from the triad of *correlational*, *spectral*, and *vacuum-response* measures (and their temporal counterparts) rather than imposed as primitive background. At the foundation stands the tetralemma—the *Fourfold Algebra of Symmetry*, ($\overset{\circ}{\mathbf{\Lambda}}$), (Symmetry, Antisymmetry, Parasymmetry, Holosymmetry)—treated as a generative grammar whose concrete vocabulary is the full algebra of observables, deliberately prior to geometric assumptions.

The quantum holo-state $\omega^{\overset{\circ}{\mathbf{\Psi}}}$ is the global, holosymmetric state on the algebra that, via the Gelfand–Naimark–Segal (GNS) construction, converts valuations into *operational expectation values* and forges the inner products that knit local fibres into an emergent Hilbert arena, $\mathcal{H}_{\text{em}}$ and $\mathcal{H}_{\text{phys}}$, and its relational geometry. This forging proceeds through the fourfold inter-modal correlator $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]$, which couples the tetralemmatic modes and supplies the state-conditioned structure required for parallel transport

$$\langle\psi_1|\psi_2\rangle_{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}} := \lim_{x'\to x} \langle\overset{\circ}{\mathbf{\Psi}}|\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]|\overset{\circ}{\mathbf{\Psi}}\rangle$$

and comparison across the continuum:

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] := \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x') \ \in\ \mathcal{B}(\mathcal{H}_{\text{em}}),$$

where $\mathcal{U}(x \leftarrow x'; \gamma)$ is the gauge–covariant transporter along the path γ, and $\mathcal{B}(\mathcal{H}_{\text{em}})$ is the Banach *-algebra (indeed C*-algebra) of bounded operators on the emergent Hilbert space $\mathcal{H}_{\text{em}}$, with implicit summation over the modal indices α, β understood.

Two novel fundamental fields, $\hat{\mathcal{F}}_\alpha^\dagger(x)$ and $\hat{\mathcal{F}}_\beta(x')$, have been proposed to inhabit this structure. The *Gaiamiti* $\hat{\mathbf{\Phi}}_x$ shapes chronogeometry and carries the radiative content associated with the graviton; the *Tantrakyma* $\hat{\mathbf{\Theta}}_x$ organises excitations and internal symmetries, seeding particle spectra and interactions. Their interaction correlators, varied as a single operational action, yield the *Chronogeometric Einstein Equations*—a covariant, state-conditioned field

system that explicitly unifies general relativity with quantum mechanics, taking the form

$$\underbrace{\bar{\Sigma}_{\mu\nu}(x)}_{\text{General Relativity}} = \underbrace{\Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \hat{\Sigma}_{\mu\nu}(x) \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle}_{\text{Quantum Mechanics}} = \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \Big(\hat{g}_{\mu\nu}(x) + \hat{t}_{\mu\nu}(x) \Big) \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle,$$

$$\bar{G}_{\mu\nu}[\bar{\Sigma}] + \Lambda\, \bar{\Sigma}_{\mu\nu} = \kappa\, \bar{T}^{\text{total}}_{\mu\nu}(x).$$

This tensor $\hat{g}_{\mu\nu}(x)$ is itself emergent, defined as the second Fréchet variation of the squared composite distance operator $D^2(x, x')$, evaluated at the coincidence limit:

$$\hat{g}_{\mu\nu}(x) := \frac{\partial^2}{\partial x^\mu \partial x'^\nu} D^2(x, x') \Big|_{x'=x},$$

where $D^2(x, x') := \hat{d}^2_{\text{corr}}(x, x') + \hat{d}^2_{\text{vac}}(x, x') + \hat{d}^2_{\text{spec}}(x, x')$. Each $\hat{d}_a(x, x')$ for $a \in \{\text{corr}, \text{vac}, \text{spec}\}$ is a Hermitian operator on $\mathcal{H}_{\text{total}}$. Complementing the metric tensor that governs emergent space, the framework defines its temporal analogue: the *operator-valued temporal curvature tensor* $\hat{t}_{\mu\nu}(x)$ arises from the triadic operators of relational time. It is formally defined as the second Fréchet variation of the squared composite temporal displacement $T^2(x, x')$ at the coincidence limit:

$$\hat{t}_{\mu\nu}(x) := \frac{\partial^2}{\partial x^\mu \partial x'^\nu} T^2(x, x') \Big|_{x'=x},$$

where $T^2(x, x') := \hat{t}^2_{\text{corr}}(x, x') + \hat{t}^2_{\text{vac}}(x, x') + \hat{t}^2_{\text{spec}}(x, x')$.

Cosmology is posed as a timeless problem $\hat{H}_{\text{univ}} | \overset{\circ}{\mathbf{\Psi}} \rangle = 0$ with $\hat{H}_{\text{univ}} := \hat{H}_\Phi + \hat{H}_\Theta + \hat{H}_{\text{int}}$: a universal quantum constraint fixes the realised state of the whole, while familiar evolutions appear when suitable internal clocks are conditioned from it. Within this discipline, the *Standard Model* is the holosymmetric, Becchi–Rouet–Stora–Tyutin (BRST)-physical realisation of the Tantrakyma sector: the anomaly-free gauge stack $G_{\text{SM}} = SU(3)_C \times SU(2)_L \times U(1)_Y$ acting on the matter registers, with Yukawa couplings and family structure fixed by cohomological and duality selection rules; electroweak symmetry breaking is a Tantrakyma vacuum alignment that produces observed masses and mixings as operational expectation values. The dark sector—dark matter and dark energy—arises as complementary holosymmetric branches of the same operator-geometric substrate rather than as an ad hoc addition, so that the full cosmic stack is given by

$$\begin{aligned} \mathcal{G}_{\text{Cosmos}} &= \underbrace{\mathcal{G}_{\text{Chronogeometry}}}_{\text{acts on } \delta\hat{\Sigma}_{\mu\nu} = \hat{h}_{\mu\nu} \oplus \hat{\tau}_{\mu\nu}} \times \underbrace{G_{\text{SM}}}_{\text{Tantrakyma (matter/gauge)}} \\ &= \Big[\text{Diff}_{\text{rel}} \ltimes \Big(\text{SO}(1,3)_{\text{local}} \times \mathcal{G}^{(\text{eff})}_{\text{Dark}} \Big) \Big] \;\times\; \Big[SU(3)_C \times SU(2)_L \times U(1)_Y \Big]. \end{aligned}$$

With

$$\mathcal{G}_{\text{Chronogeometry}} := \text{Diff}_{\text{rel}}(\mathcal{X}_q) \;\ltimes\; \Big(\text{SO}(1,3)_{\text{local}} \;\times\; \mathcal{G}^{(\text{eff})}_{\text{Dark}} \Big).$$

Here $\text{Diff}_{\text{rel}}(\mathcal{X}_q)$ are relational diffeomorphisms on $(\mathcal{X}_q, \bar{\Sigma})$, acting by pullback on fields and adjoint transport on internal fibres; $\text{SO}(1,3)_{\text{local}}$ are local Lorentz rotations; and $\mathcal{G}^{(\text{eff})}_{\text{Dark}}$ is the

effective symmetry badge governing the proposed τ–kairos (not SM matter):

$$\mathcal{G}^{(\mathrm{eff})}_{\mathrm{Dark}} \supset \underbrace{\mathrm{Shift}_{\varphi_b} \times \mathrm{Shift}_{\varphi_L} \times \mathrm{Shift}^{\mathrm{ax}}_{\tilde{\varphi}}}_{\text{scalar shifts}} \times \underbrace{U(1)_\tau}_{\text{Chrono–Kymon phase}} \times \underbrace{U(1)_{\mathrm{hel}}}_{\text{helicity plane}} \times \underbrace{\mathbb{Z}_2^{\mathrm{HS}}}_{\text{HSP tag}} .$$

The three Shift factors act on the breathing/longitudinal/axial scalars $(\varphi_b, \varphi_L, \tilde{\varphi})$; $U(1)_\tau$ is the proposed *Chrono–Kymon* phase symmetry of the τ-vector $K^{(\tau)}$; $U(1)_{\mathrm{hel}} \simeq SO(2)$ rotates the helicity doublet $(K^{(\tau)}_+, K^{(\tau)}_-)$; and $\mathbb{Z}_2^{\mathrm{HS}}$ labels *holosymmetric* (HSP) branch stability arising from algebra. All continuous factors are *effective* and may be softly broken by the same operators (masses, mixings, potentials) that drive cosmology.

In concise form, the emergence chain is

$$\mathrm{Ontology} \rightsquigarrow \mathrm{Algebra} \rightsquigarrow \mathrm{GNS/BRST}:$$
$$(\overset{\circ}{\mathbf{\Lambda}}),\ \mathcal{A}(\mathcal{C}_d) \rightsquigarrow (\mathcal{H}_{\mathrm{em}}, \hat{Q}_{\mathrm{BRST}}) \rightsquigarrow \mathcal{H}_{\mathrm{phys}} \simeq H^0_{\mathrm{BRST}}.$$

On this arena, $\hat{\mathbf{\Phi}}$ (geometry) and $\hat{\mathbf{\Theta}}$ (matter), with their interaction correlators, enter a single action whose variation yields the Chronogeometric Einstein Equations,

$$S[|\overset{\circ}{\mathbf{\Psi}}\rangle] := \int_{\mathcal{X}_q} d^d x\ \sqrt{-\det \bar{\Sigma}(x)}\ \mathrm{Tr}\Big(\Big\langle \overset{\circ}{\mathbf{\Psi}}\Big| \hat{\mathbf{G}}_\Lambda(x,x) \Big|\overset{\circ}{\mathbf{\Psi}}\Big\rangle\Big) .$$

By rooting metrics, clocks, and spectra in the same fibred continuum and relational phase-geometry bundle, the framework unifies ontology, kinematics, and phenomenology without imported scaffolds, offering a clean trajectory from question to detection, from detector readout to cosmos, and from algebra to evidence.

The evolution of any such subsystem is governed by this emergent dynamical law

$$i\hbar \frac{d}{dt} |\overset{\circ}{\mathbf{\Psi}}(t)\rangle = \hat{H}_{\mathrm{rel}}(t) |\overset{\circ}{\mathbf{\Psi}}(t)\rangle,$$

and the operator that drives this effective evolution is the *total relational Hamiltonian* $\hat{H}_{\mathrm{rel}}$, which contains the entirety of cosmic phenomenology:

$$\hat{H}_{\mathrm{rel}} = \underbrace{\hat{H}_{\mathrm{geometry}}[\hat{\Sigma}_{\mu\nu}]}_{\text{Dark Energy \& Dark Matter}} + \underbrace{\hat{H}_{\mathrm{matter}}[\hat{\phi}, \hat{\psi}, \dots]}_{\text{Standard Model}} .$$

This single effective Hamiltonian is composed of two sectors:

The Geometric Hamiltonian ($\hat{H}_{\mathrm{geometry}}$) This operator governs the dynamics of the Gaiamiti field ($\hat{\Phi}$), whose quanta are the *apeirons*. Its ground state eigenvalue is the cosmological constant (Λ), the physical origin of *Dark Energy*, while its large-scale coherent excitations are the physical manifestation of *Dark Matter*.

The Matter Hamiltonian ($\hat{H}_{\mathrm{matter}}$) This operator governs the dynamics of the Tantrakyma field ($\hat{\Theta}$), whose quanta are the *kymons*. Its excitations and their interactions give rise to the entire particle zoo of the Standard Model.

Dedication

Oṃ Namo Bhagavatyai Ārya-Prajñāpāramitāyai
Oṃ Homage to the Blessed and Noble Perfection of Wisdom

Namaḥ sarvajñāya
Homage to the All-knowing, the Omniscient

Inexpressible, inconceivable, and unutterable
Is the Perfection of Wisdom, Prajñāpāramitā.
She is unborn, unceasing, the nature of space.
The object of experience of self-cognizant primordial wisdom.

For the Wellbeing and Joy of all Beings and Worlds
And for the Perfection of Wisdom.

5.3.5 Holosymmetric Wordwise Lorentzian Structure from the Unified Tensor . . . 656
5.3.6 Symmetrizing the Unified Lorentzian Tensor . . . 657
5.3.7 Holosymmetric Wordwise Symmetrization of the Unified Lorentzian Tensor 659
5.3.8 Emergent Proper Time and Distance . . . 662
5.3.9 Metric Projection . . . 663
5.3.10 Holosymmetric Wordwise Emergence of Proper Time and Distance . . . 664
5.3.11 Holosymmetric Wordwise Metric Projection . . . 666
5.3.12 The Emergent Chronogeometric Manifold . . . 667
5.3.13 Holosymmetric Wordwise Emergent Chronogeometric Manifold . . . 668
5.3.14 The Nature of Spacetime: An Emergent, Relational Tapestry . . . 671
5.4 Causal Structures on the Chronogeometric Manifold . . . 672
5.4.1 The Effective Light Cone and its Primordial Origin . . . 672
5.4.2 Holosymmetric Wordwise Effective Light Cone and PQS Apex . . . 675
5.4.3 The Dynamical Texture: The Temporal Phase-Flow Structure . . . 677
5.4.4 A Complementary Two-Layered Causal Architecture . . . 678
5.4.5 The Unified Causal Architecture . . . 685
5.4.6 The Primordial Origin of Causality . . . 690
5.4.7 Holosymmetric Wordwise Primordial Origin of Causality . . . 692

III Laws, States and Fundamental Fields 701

6 The Gaiamiti and Tantrakyma Fields 702
6.1 The Nature of the Fundamental Fields . . . 702
6.1.1 The Inter-Modal Correlator Matrix of the Fields . . . 713
6.1.2 Holosymmetric Wordwise Unified Inter-Modal Correlator . . . 715
6.1.3 The Relational Levi-Civita Derivative . . . 723
6.1.4 Holosymmetric Wordwise Relational Levi-Civita . . . 725
6.1.5 The Determinant of the Effective Lorentzian Metric . . . 738
6.1.6 Holosymmetric Wordwise Determinant of the Effective Lorentzian Metric 739
6.1.7 Holosymmetric Wordwise Relational Volume Element . . . 742
6.1.8 The Vacuum Manifold: Variational and Spectral Formulation . . . 745
6.1.9 Holosymmetric Wordwise Formulation of the Vacuum Manifold . . . 748
6.1.10 The Trace of the Inter-Modal Correlator . . . 752
6.1.11 Holosymmetric Wordwise Trace of the Inter-modal Correlator . . . 753
6.1.12 Holosymmetric Control Dial — Fourfold Inter-modal Trace . . . 754
6.1.13 The Relational Hamiltonian . . . 755
6.1.14 Holosymmetric Wordwise Relational Hamiltonian . . . 757
6.1.15 Holosymmetric (HS) Extension of the Relational Hamiltonian . . . 759
6.1.16 Quantum Circuit Realization of the HS Relational Hamiltonian . . . 761
6.1.17 The Vacuum Manifold . . . 763
6.1.18 Holosymmetric Wordwise Vacuum Manifold . . . 765

6.1.19 Quantum Circuit Realization of the Vacuum Manifold . . . 771
6.1.20 An Operator-Theoretic Definition of the Tangent Bundle . . . 774
6.1.21 Holosymmetric Wordwise Tangent Bundle of the Vacuum . . . 776
6.1.22 Holosymmetric Lift of the Tangent Bundle of the Vacuum . . . 780
6.1.23 Quantum Circuits for the Vacuum Manifold and its Tangent Bundle . . . 782
6.1.24 Inner Product on the Vacuum Tangent Space . . . 784
6.1.25 Holosymmetric Wordwise Inner Product on the Vacuum Tangent Bundle 785
6.1.26 The Banach Space of Bounded Operators . . . 787
6.1.27 The Algebra of Endomorphisms: The Arena for Quantum Operators . . . 788
6.1.28 Holosymmetric Wordwise Banach Space and Endomorphism Bundle . . . 789
6.2 The Dynamical Gaiamiti Field . . . 793
6.2.1 Holosymmetric Wordwise Dynamical Gaiamiti Field . . . 794
6.2.2 The HS Quantum Circuits of the Gaiamiti Field . . . 802
6.3 The Dynamical Tantrakyma Field . . . 807
6.3.1 Holosymmetric Wordwise Dynamical Tantrakyma Field . . . 808
6.4 Bundle-Theoretic Formulation of the Foundational Fields . . . 812
6.4.1 Holosymmetric Wordwise Bundle-theoretic Formulation of the Foundational Fields . . . 815
6.5 The Action for the Dynamical Gaiamiti Field . . . 819
6.5.1 The Gaiamiti Field Action Functional . . . 820
6.5.2 The Holosymmetric Action for the Dynamical Gaiamiti Field . . . 821
6.5.3 Covariant Derivative of the Gaiamiti Field . . . 823
6.5.4 Holosymmetric Covariant Derivative of the Gaiamiti Field . . . 824
6.6 The Operator Bundle Connection as an Emergent Gauge Field . . . 828
6.6.1 Holosymmetric Operator Bundle Connection as an Emergent Gauge Field 829
6.7 Spontaneous Symmetry Breaking . . . 835
6.8 Emergent (Asymmetry-Induced) Symmetry . . . 837
6.9 Weaving The Two Arrows of Symmetry . . . 839
6.10 BRST Quantization and Ghosts: A Cohomological Prelude . . . 842
6.11 From Duality to the Symmetry–Asymmetry Quadrants . . . 849
6.11.1 Duality, Lifted to Two Layers . . . 849
6.11.2 Two Dyads and Their Product . . . 849
6.11.3 BRST-Compatible Reading . . . 850
6.11.4 Identification of the Quadrants and Mechanisms . . . 852
6.11.5 Holosymmetric Meta-Layer: Two-path Law/State Interferometry . . . 856
6.11.6 Operational Holosymmetric Cartography of the Quadrants . . . 867
6.11.7 Channel-Resolved Holosymmetric Diagnostics . . . 875
6.12 Scale-Aware Analysis for the Laws–State Matrix . . . 883
6.12.1 Purpose and Proviso . . . 883
6.12.2 Variational Backbone for Each Quadrant . . . 883
6.12.3 Operational Diagnostics (Scale-aware, Channel-resolved) . . . 898
6.12.4 Scale-tagged Variational Infrastructure (IR/UV) . . . 903
6.12.5 Working Strategy to Traverse the Quadrants . . . 928
6.12.6 IR/UV-aware Add-ons and Deliverables . . . 929
6.12.7 Practical Ledgers (Maintained Throughout) . . . 930

7 Field Laws and Physical States **931**
7.1 Quadrant I: Symmetric Vacuum and Scale-Tagged EOM . . . 931
7.1.1 Background Split and Vacuum Equations . . . 931
7.1.2 Scale-tagged Sector Actions and Euler–Lagrange Operators . . . 932
7.1.3 BRST-consistent Reading on $\mathcal{H}_{\text{phys}}$ . . . 932
7.1.4 UV/IR Knobs and Geometric Inputs . . . 933
7.1.5 Symmetric Vacuum at Scale (What the EOM Demand) . . . 933
7.2 BRST Health and Spectrum at the Symmetric Vacuum (Quadrant I) . . . 935
7.2.1 BRST Complex, Nilpotency, and the Physical Sector . . . 935
7.2.2 Gauge-fixed Quadratic Theory, Propagators, and Cohomological Invariance 936
7.2.3 Spectrum at the Symmetric Vacuum (Quadrant I) . . . 937
7.2.4 Scale Tags, Plateaus, and Robustness . . . 937
7.2.5 Quadratic Action, Hessian, and Transverse/Longitudinal Split . . . 938
7.2.6 Ghost Decoupling and Positivity on $\mathcal{H}_{\text{phys}}$ . . . 940
7.2.7 Tachyon Test and Hyperbolicity of the Physical Operator . . . 941
7.2.8 Anomaly Filters and Quantum BRST . . . 942
7.2.9 Gauge-parameter Independence of the Physical Poles (Nielsen Identities) . 945
7.2.10 Bandwise Checklist and Certification . . . 947
7.3 UV/IR Knobs and Plateau Certification . . . 949
7.3.1 Definitions of the UV/IR knobs . . . 950
7.3.2 Plateau Metrics and Acceptance Criteria . . . 954
7.3.3 Operational Certification Protocol . . . 958
7.3.4 Visibilities and their Scale Dependence . . . 960
7.3.5 Plateau Regions: Geometric Definition . . . 964
7.3.6 Gauge/BRST Robustness (Nielsen-type Independence) . . . 972
7.3.7 Regularisation Stability (Kernel/Projector Families) . . . 975
7.3.8 Channel-wise and Integrated Visibilities . . . 982
7.3.9 Acceptance Criteria and Certification Pipeline . . . 992
7.3.10 Quantitative Plateau Metrics . . . 995
7.3.11 Channel and Sector Compatibility . . . 997
7.3.12 Outcome and Policy Note . . . 999
7.4 Holosymmetric Probe: Controlled Two-path Evolution and Visibilities . . . 1000
7.4.1 Readout and Complex Coherence Amplitude . . . 1008
7.4.2 Channel Realisations: Law vs. State . . . 1011
7.4.3 Embedding of UV/IR Knobs and Sector Projectors . . . 1015
7.4.4 Gauge/BRST Robustness and Anomaly Filters . . . 1021
7.4.5 Plateau Coupling and Certification . . . 1026
7.4.6 Error Budget and Robustness to Noise . . . 1028
7.5 Exact Identities at the Symmetry Point (Baseline for Symmetry Breaking) . . . 1030
7.5.1 Band-limited Source Formalism and BRST-exact Gauge Fixing . . . 1030
7.5.2 Slavnov–Taylor Identity and Linearized Operator . . . 1032
7.5.3 Gauge-fixing, Antighost, and b-equations . . . 1034
7.5.4 Global G Ward Identities at the Dymmetric Vacuum . . . 1043
7.5.5 Nielsen Identity at the Symmetry Point . . . 1050
7.5.6 Cohomological Content and Physical Operators . . . 1055

7.5.7 Background-field Option . . . 1056
7.5.8 Global Ward Identities at the Symmetric Point . . . 1058
7.5.9 Slavnov–Taylor Identity and its Linearisation . . . 1063
7.5.10 BRST Charge, Nilpotency, and Equivalence Theorem . . . 1067
7.5.11 Nielsen Identities at the Symmetry Point . . . 1072
7.5.12 Callan–Symanzik Identity on the Band . . . 1075
7.5.13 Sector/Projector Compatibility and Plateau Protection . . . 1080
7.5.14 Anomaly Filters and Cohomological Triviality . . . 1086
7.5.15 Identity Ledger for Later SSB Analysis . . . 1088
7.6 Synthesis of Quadrant I: Discoveries and Baseline Status . . . 1089
7.7 Quadrant II: Spontaneous Symmetry Breaking (SSB) . . . 1091
7.7.1 Hold the Law Symmetric (Keep H_0 Fixed) . . . 1091
7.7.2 Prepare an Asymmetric State on the Vacuum Manifold . . . 1101
7.7.3 Band Hessian to BRST Projection (Transverse/Longitudinal) . . . 1111
7.7.4 Read Visibilities: Verify $|\Lambda_{\text{law}}| \approx 1$; Volume Decay of $|\Lambda_{\text{state}}|$; Phase–twist Interferometry for NG Soft Limits . . . 1122
7.7.5 Plateau Certification and Gauge-parameter Independence . . . 1132
7.7.6 Identity Ledger: Slavnov–Taylor, Ward, Nielsen, and Callan–Symanzik (On-band, Sectorwise) . . . 1145
7.7.7 Physicality Tests: Nonnegative Spectrum, Hyperbolicity, and Spectral Positivity on $\mathcal{H}_{\text{phys}}$ . . . 1152
7.7.8 Readout Consolidation and Cross–Quadrant Comparison . . . 1159
7.8 Quadrant III: Explicit (But Small) Law Breakings . . . 1164
7.8.1 Data, Regime, and Physical Reading . . . 1164
7.8.2 Tracking Law Emergence and Defining a Robust IR Slope . . . 1190
7.8.3 Restoration Length . . . 1219
7.8.4 RG Ledger: Breakings Become Irrelevant . . . 1230
7.8.5 Ward/ST/Nielsen Closure (Band–Projected) . . . 1251
7.8.6 Spectral Reconvergence to Symmetric Multiplets . . . 1268
7.8.7 Plateau Certification (Q III Mask) . . . 1291
7.8.8 Physicality Strengthens with ℓ . . . 1303
7.8.9 QIII Lessons & IR “Particle-like” Outlook . . . 1316
7.8.10 Concluding Census of Particle-like Modes on the QIII Plateau . . . 1317
7.9 Quadrant IV: Explicit Law Breaking with an Asymmetric State . . . 1320
7.9.1 UV/IR Instrumentation and Visibility Order Parameters . . . 1322
7.9.2 Fix the Symmetry Reference & Spurions . . . 1330
7.9.3 Cone–preserving Kernels . . . 1342
7.9.4 Visibilities (Primary Diagnostics) . . . 1346
7.9.5 State–visibility guardrail (no SSB / no decoherence of vacua) . . . 1352
7.9.6 State–visibility Envelope Selection, CIs, and Fallback Protocol . . . 1359
7.9.7 Law–visibility Slope Test and Tomographic Calibration . . . 1363
7.9.8 T-odd Tomography & Cones (No Law-signalling; Anomaly Filters) . . . 1370
7.9.9 Law–channel Diagnosis: Saturation vs. QIII . . . 1377
7.9.10 Near–degeneracies and GMOR Fits in the Mass Ledger . . . 1380
7.9.11 Ward–mass Link (GMOR–type Control of Pseudo–NG) . . . 1383

7.9.12 Multi–spurion GMOR Fits and PCAC/LSZ Bandwidth on the Plateau . . 1392
7.9.13 Gauge/BRST Safety & Spectral Shifts 1398
7.9.14 Gauge–flatness Audit and Analytic Tracking Window in $\{\epsilon_k\}$ 1406
7.9.15 Plateau–mask Certification (Report Only Where Robust) 1410
7.9.16 Numerical Thresholds and Grid–refinement Schedule for the Mask 1416
7.9.17 Channel–resolved Holosymmetric Readout 1419
7.9.18 Channel–resolved Readout: Operational Note (What Drives What) 1425
7.9.19 Synthesis of QIV 1429
7.10 Consolidation of Law–State Signatures, Ward Sources, and Spectral Content (QI–QIV) 1435
7.10.1 Comparative Table 1440

8 Parasymmetric Witnesses and Diagnostics 1448
8.1 Sector-Conditioned Witnesses and Quadrant Rules 1448
8.1.1 Fermionic Witnesses 1453
8.1.2 SUSY Witnesses 1455
8.1.3 p-Forms Witnesses 1457
8.1.4 Higher Spins Witnesses 1458
8.1.5 Hydrodynamics Witnesses 1459
8.1.6 Second Sound in the Hydrodynamic Sector (Matrix Formulation) 1461
8.1.7 Boundary Soft/Edge Modes Witnesses 1464
8.1.8 Anyons (Chern-Simons) Witnesses 1466
8.1.9 Fractons Witnesses 1467
8.1.10 Higher-Forms and Non-Invertible Symmetries 1470
8.1.11 Anomaly Witnesses 1471
8.1.12 Non-equilibrium (Floquet/Lindblad) Witnesses 1472
8.1.13 Universal Quadrant Coverage 1475
8.2 The Synthesis of Laws and States 1479
8.2.1 Parasymmetric Synthesis of Laws and States 1490
8.2.2 Parasymmetry (with SynTh) vs. Duality 1500
8.3 SynTh of Generalized Witness of Laws and States 1502
8.4 Parasymmetric Synthesis of Laws and States (Sector-conditioned Overlay) . . 1511
8.5 Applications of Parasymmetric Overlays 1514
8.5.1 Sector-Agnostic Parasymmetric Overlay 1516
8.5.2 Parasymmetric Overlay of the Fermionic (Spin-1/2) Sector 1518
8.5.3 Parasymmetric Overlay of Supersymmetry (SUSY) 1523
8.5.4 Parasymmetric Overlay of Boundary Soft/Edge Modes 1529
8.6 Parasymmetric Diagnostics of Type, Location, and Onset (TLO) 1532
8.6.1 Parasymmetric Meters and Laws-States Quadrant Readings 1532
8.6.2 Locator Sets: “Where” the Patterns Occur 1533
8.6.3 Onset Scales and Times: “When” the Patterns Occur 1534
8.6.4 Boundary/Edge Arenas and Sector Checks 1534
8.6.5 Typed Sector Witnesses and Parasymmetric Meters (Spin/Helicity/Polarization–conditioned) 1535
8.6.6 Spectral–Only Parasymmetric Protocol 1538

8.6.7 Application Arenas for SynTh ⊕ Parasymmetry (Typed Witnesses) . . . 1540
8.6.8 Parasymmetric Readout of Second Sound . . . 1542

9 The Quanta of Fields **1545**
9.1 Arena, Transport, Grading, and Band Tagging . . . 1550
9.2 Law vs. State, Visibilities, and the Four Quadrants (Pre-Physical) . . . 1556
9.3 From Algebraic Breakings to Quanta . . . 1563
9.4 Pre-physical Symmetry Reduction (PSR) . . . 1573
9.5 Realization to the BRST-physical Sector and Spectrum . . . 1584
9.6 Minimal "How-to" Pipeline . . . 1594
9.7 Invariance of Chronogeometric Formalisms . . . 1596
9.8 Parasymmetric Type–Location–Onset on the Sigma Pre-Physical Layer . . . 1597
9.9 Σ–Pre-physical Cones and Causality (Operator Level) . . . 1606
9.10 Kinematic Permit Census for Apeiron/Kymon (No *a priori* Spins) . . . 1613
9.11 Typed Σ–Contrasts & Visibilities (Pre-Physical) . . . 1622
9.12 Parasymmetric Meters on the Band (Typed) . . . 1633
9.13 Per Sector Execution Outline . . . 1640
9.14 Audits & Guardrails . . . 1648
9.15 Pre-Physical Artefacts . . . 1654
9.15.1 Typed Pre-Physics: Ledger, Visibilities, TLO . . . 1660
9.15.2 Permitted Kinematics for the Gaiamiti (Apeiron, ΦΦ) Field . . . 1662
9.15.3 Permitted Kinematics for the Tantrakyma (Kymon, ΘΘ) Field . . . 1663
9.15.4 Pre-Physics Parasymmetric Admission, Mechanism, Onset . . . 1665
9.16 Typed Parasymmetric Quadrants of the Gaiamiti and Tantrakyma Fields . . . 1666
9.16.1 Typed Subspaces and Projectors . . . 1672
9.16.2 Applying Parasymmetric Meters to Typed Subspaces . . . 1676
9.16.3 Assigning the Quadrant Per Type (Canonical decision on H^0) . . . 1679
9.16.4 Recording the Type, Location, and Onset (TLO) . . . 1681
9.17 The Gaiamiti Field Potential and the Origin of the Apeiron . . . 1683
9.17.1 The Apeiron as the Fundamental Quantum of Geometry . . . 1699
9.17.2 Spontaneous Symmetry Breaking of the Gaiamiti Field . . . 1703
9.17.3 Global Symmetry Breaking: NG and Radial Sectors . . . 1706
9.17.4 Internal Gauging of the Gaiamiti Sector and BEH Completion . . . 1710
9.17.5 The Composite Nature of the Goldstone Mode . . . 1716
9.17.6 The Emergence of the Massless Graviton via SSB . . . 1720
9.17.7 Euler–Lagrange Equation for the Gaiamiti Field . . . 1721
9.17.8 Noether Current for the Dynamical Gaiamiti Field . . . 1725
9.17.9 The Noether Stress–Energy Tensor of the Gaiamiti Field . . . 1732
9.17.10 Projection Operators and Geometric Duality . . . 1736
9.17.11 Tantrakyma Parasymmetric Type, Location, and Onset . . . 1741
9.18 The Action for the Dynamical Tantrakyma Field . . . 1743
9.18.1 The Tantrakyma Field Action Functional . . . 1749
9.18.2 Holosymmetric Wordwise Tantrakyma Field . . . 1752
9.18.3 Covariant Derivative of the Tantrakyma Field . . . 1755
9.18.4 Holosymmetric Wordwise Tantrakyma Covariant Derivative . . . 1757

9.18.5 Tantrakyma Field Potential and the Origin of the Kymon . . . 1760
9.18.6 Spontaneous Symmetry Breaking of the Tantrakyma Field . . . 1773
9.18.7 Gauge-Coupled Tantrakyma and the Brout–Englert–Higgs Mechanism . . 1776
9.18.8 A Minimal $U(1)$ Worked Example of the BEH Mechanism . . . 1783
9.18.9 Euler–Lagrange Equation for the Tantrakyma Field . . . 1795
9.18.10 Noether Current for the Dynamical Tantrakyma Field . . . 1797
9.18.11 The Noether Stress–Energy Tensor of the Tantrakyma Field . . . 1801
9.18.12 The Source of Emergent Curvature: A Unified View . . . 1804

10 The Weave of Geometry and Matter 1808
10.1 The Inter-Modal Correlators of Fields . . . 1808
10.2 Realized Weave Configuration and Typed Algebra . . . 1810
10.3 The τ-kairos Field . . . 1822
10.4 Chronogeometric Origin and Certified Construction of the τ–kairos . . . 1829
10.5 The Graviton in the Gaiamiti (Geometry) Sector . . . 1832
10.5.1 The Graviton Six Polarization Modes (Hypothetical) . . . 1840
10.6 The Higgs (Radial Kymon) in the Tantrakyma Sector . . . 1844
10.7 The Chrono–Kymon (Vector Channel of the τ-kairos) . . . 1847
10.8 The Spin–0 Apeiron (Gaiaton): Scalar Channel in the τ-kairos . . . 1851
10.9 Witnesses, Visibilities, and Parasymmetric TLO (Full Construction) . . . 1859
10.9.1 Law and State Ledgers: Residuals and Features . . . 1860
10.9.2 Calibrated Meters and Visibilities . . . 1862
10.9.3 Monotonicity Under IR Retuning . . . 1863
10.9.4 Onset Definition, Uniqueness, and Stability Radii . . . 1864
10.9.5 Explicit Witness Contents by Type and Sector . . . 1868
10.9.6 Parasymmetric TLO: Existence, Uniqueness, and Stability . . . 1870
10.10 SynTh Resolution and Audit for the Weave . . . 1872
10.10.1 Co-tenability, Conflicts, and Thresholds . . . 1877
10.10.2 Audit Moves and Basic Monotonicities . . . 1878
10.10.3 Finite Audit Paths and No-Explosion . . . 1881
10.10.4 Trigger Thresholds and Automatic Audit . . . 1884
10.11 Weaving the Sectors via the Unified Inter-Modal Correlator . . . 1886
10.11.1 Σ-weighted Generalized Eigenproblem for Mixing . . . 1887
10.11.2 TT-null Preservation for τ-mixing . . . 1890
10.11.3 Selection Rules for Typed Mixing . . . 1891
10.11.4 Stability Bounds: Mixing Norms vs. Visibility Changes . . . 1893
10.12 Triad-Resolved Reporting with Boundary vs. Bulk Provenance . . . 1899
10.12.1 Schema and Macros for Weave Reports . . . 1899
10.12.2 Arena-Invariant Spectral Set and Typed Stability . . . 1900
10.12.3 Boundary–vs–Bulk Invariance . . . 1902
10.12.4 Stability of Reported Onsets under Arena Changes and Mixing . . . 1904
10.13 Norms, Contours, and TT-Hyperbolicity . . . 1905
10.13.1 Admissible Norm Family . . . 1906
10.13.2 Measurable Structure for Riesz Integrals . . . 1908
10.14 Findings and Quadrants: High-Level Synthesis . . . 1911

10.15 Permitted Spins, Polarizations, Helicies, and Tags: High-Level Overview . . . 1913
10.16 Fundamental Quanta and Their Excitations . . . 1917
10.17 Geometric Block of the Unified Correlator . . . 1940
10.17.1 The Apeiron: Field–level vs. Particle–level Modes . . . 1944
10.17.2 The Chronogeometric Excitations . . . 1946
10.17.3 Excitation Channels and the Role of the Tau–Kairos . . . 1951
10.17.4 Observable (Kinematic) vs. Constitutive (Microscopic) Descriptions . . . 1952
10.17.5 Relational Graviton Propagator . . . 1955
10.17.6 Triadic Decomposition of Gravitational Propagation . . . 1961
10.17.7 Covariant Dynamics of Gravitational Fluctuations . . . 1963
10.17.8 Gravitational Waves . . . 1966
10.17.9 Tantrakyma and Kymon Contributions to Chronogeometry . . . 1968
10.18 Matter Block of the Unified Correlator . . . 1974
10.18.1 Definition and Typed Placement . . . 1974
10.18.2 Background–fluctuation Decomposition . . . 1976
10.18.3 Typed resolution and admissible matter channels . . . 1976
10.18.4 Relations to cross–blocks and spectrum . . . 1976
10.18.5 Emergent Matter Propagators . . . 1977
10.18.6 Dynamical Equations and Propagation . . . 1980
10.18.7 Triadic Decomposition of the Matter Propagator . . . 1983
10.19 Matter–Geometry Block of the Unified Correlator . . . 1986
10.19.1 Typed Off–diagonal Block and Connected Kernel . . . 1986
10.19.2 Modal Representation and Transport . . . 1987
10.19.3 Triadic Resolution and Parasymmetric TLO Interface . . . 1988
10.19.4 Functional Variation of the Interaction Action . . . 1989
10.19.5 Mutually–Sourced Field Currents and Typed Reciprocity . . . 1991
10.19.6 Triadic Decomposition of the Interaction Channels . . . 1992

11 The Graviton and Chronogeometric Gravity 1995
11.1 Quantization and Interaction of the Geometric Sector . . . 1995
11.1.1 Canonical Quantization of the Gaiamiti Field . . . 1999
11.1.2 Covariant Quantization via the Peierls Bracket . . . 2010
11.1.3 Graviton Mode Decomposition from Gaiamiti Fluctuations . . . 2014
11.1.4 Triadic Decomposition of the Graviton Field . . . 2032
11.1.5 Graviton Fock Space and Multi-Particle States . . . 2035
11.2 The Graviton Propagator . . . 2037
11.2.1 The Time-Ordering Operator and the Feynman Propagator . . . 2039
11.2.2 Mode Expansion and the Operator Basis of the Propagator . . . 2041
11.2.3 Graviton Propagator in Background Geometry . . . 2045
11.2.4 Triadic Structure and Interpretation of the Graviton Propagator . . . 2049
11.2.5 A Composite Gravitational Force and its Predictions . . . 2050
11.3 Graviton-Mediated Scattering . . . 2051
11.3.1 Linearized Interaction Action . . . 2053
11.3.2 Structure of the Vertex from the Interaction Kernel . . . 2053
11.3.3 Graviton Coupling Channels (modal decomposition) . . . 2054

11.3.4 Scattering Amplitudes from Graviton Exchange . . . 2054
11.3.5 Effective Graviton-Mediated Propagation . . . 2055
11.3.6 Positivity and Dispersion Bounds for Triadic Exchange . . . 2056
11.3.7 Graviton-Mediated Tantrakyma Scattering . . . 2057
11.3.8 Effective Graviton-Mediated Propagation . . . 2057
11.3.9 Graviton Coupling Channels . . . 2060
11.3.10 Scattering Amplitudes from Graviton Exchange . . . 2063
11.3.11 Effective Graviton-Mediated Propagation . . . 2064
11.3.12 Graviton-Mediated Tantrakyma Scattering . . . 2066
11.3.13 Positivity/Dispersion Bounds for Triadic Graviton Exchange . . . 2069
11.4 Geometry–matter interface in the typed (TT) formalism. . . . 2075
11.4.1 The Feynman Rules for Matter and Geometry . . . 2077
11.5 The Chronogeometric Gravity . . . 2079
11.5.1 The Unified Riemann Curvature Tensor . . . 2081
11.5.2 Ricci Tensor and Scalar Curvature of the Unified Geometry . . . 2085
11.5.3 The Relational Einstein–Hilbert Action . . . 2086
11.5.4 Unified Semi–Classical Einstein Equations . . . 2087
11.5.5 Derivation of the Unified Semi–Classical Einstein Equations . . . 2090
11.5.6 The Emergent Gravitational Coupling Tensor . . . 2095
11.5.7 Scalarisation, Universality, and Variation Bounds of the Gravitational Coupling Tensor . . . 2098
11.5.8 Recovery of General Relativity in the Spectral Limit . . . 2102
11.6 A Coherence–Energy Condition (Relational NEC) . . . 2105
11.7 Operator–Valued Einstein Equations with Unified Tensor . . . 2120
11.7.1 Formulation of the Operator Equation . . . 2120
11.7.2 Consistency, Conservation, and Semiclassical Reduction . . . 2121
11.7.3 The Einstein Tensor of the Unified Geometry . . . 2123
11.7.4 What is Gravity in the IQR Framework? . . . 2125
11.8 Chronogeometry of the τ–Kairos . . . 2138
11.8.1 Linear–response Quantization of the Non–TT sector and Optional BEH Mass for Chrono-Kymons . . . 2145
11.8.2 BEH of the Chrono-Kymon . . . 2147
11.8.3 The Chrono-Kymon as a Unified Dark Sector Candidate . . . 2152
11.8.4 BEH of the Gaiaton . . . 2153
11.8.5 Gaiaton as the Dark Matter and Energy Candidate . . . 2161
11.9 The Chronogeometric Regimes . . . 2163

IV The Standard Model 2169

12 The Standard Model 2170
12.1 Cosmic Constraints and Candidate Symmetry Groups . . . 2173
12.1.1 Characterization of the Candidate Symmetry Group . . . 2174
12.1.2 Matching to the Observed Fermion Content . . . 2201
12.1.3 The Anomaly Cancellation Constraint . . . 2204

12.2 The Holosymmetric Selection Principle (HSP) . . . 2211
12.2.1 Holothesis and the Superposition of Laws (Holosymmetry) . . . 2215
12.2.2 Stage I — The Self-Consistency Filter (Symmetric Interferometer) . . . 2216
12.2.3 Stage II — Comparative Tomography and Relational Orthogonality (Asymmetric Interferometer) . . . 2217
12.2.4 The Holosymmetric Selection Principle (HSP) . . . 2221
12.2.5 Structural Interlocks with the Foundations . . . 2223
12.3 BRST Symmetry and the Quantization of Gauge Fields . . . 2235
12.3.1 The Extended Field Space . . . 2236
12.3.2 BRST Cohomology and the Holosymmetric Selection Principle . . . 2248
12.4 The Emergence of Fermions from the Graded Tantrakyma Field . . . 2263
12.4.1 Leptons and Quarks as Irreducible Tantrakyma Representations . . . 2270
12.4.2 Representation Action of G_{SM} on Fermionic Kymons . . . 2272
12.4.3 Emergence of the Gell–Mann–Nishijima Relation from Tantrakyma Field Dynamics . . . 2282
12.4.4 Gauge Bosons as Excitations of the (Internal) Gauge Part of the Operator–Bundle Connection . . . 2288
12.4.5 Electroweak Symmetry Breaking via the Tantrakyma Potential . . . 2293
12.4.6 Fermion Masses from Yukawa Coupling to the Tantrakyma Field . . . 2297
12.5 The Threefold Multiplicity of Chiral Matter . . . 2301
12.5.1 From Triadic Time to a $\mathbb{C}^3$ Family Fibre . . . 2302
12.5.2 Why Exactly Three Families: a Minimal–faithful Holonomy Theorem . . . 2306
12.5.3 Family Connection, Yukawa Structure, and Flavor Mixing . . . 2310
12.5.4 Anomaly and HSP Compatibility . . . 2311
12.5.5 Flavor Mixing via the CKM and PMNS Matrices . . . 2313
12.5.6 The Inevitable Emergence of Mixing Matrices . . . 2317
12.5.7 Hadrons as Composite Kymon States . . . 2319
12.6 BRST Cohomology and the Hadronic Physical Space . . . 2329
12.6.1 Constraints, BRST Charge, and Nilpotency . . . 2329
12.6.2 Color Singletness and BRST Physicality . . . 2330
12.6.3 Typed Placement and Graviton Purity . . . 2330
12.6.4 Family Neutrality and Flavor Structure . . . 2330
12.6.5 Quartet Mechanism and Gauge–Invariant Reduction . . . 2331
12.6.6 Explicit Computation on the Hadronic Sector . . . 2333
12.6.7 Compatibility with Spectral Filtering and HSP . . . 2334
12.6.8 Technical Notes on Domains and Positivity . . . 2335
12.7 Neutrino Masses, the Seesaw, and PMNS Mixing . . . 2335
12.7.1 Neutrino Physics and the Majorana Seesaw Mechanism . . . 2335
12.7.2 PMNS Mixing in the Dirac and Majorana Cases . . . 2336
12.7.3 Dirac–Majorana Sector from the Tantrakyma . . . 2339
12.7.4 Type-I seesaw from block diagonalization . . . 2340
12.7.5 PMNS Mixing from Misalignment . . . 2343
12.7.6 Constraints from the Tantrakyma Potential and Family Fibre . . . 2345
12.7.7 Neutrino Mass and the Majorana Seesaw Mechanism . . . 2346
12.7.8 Gauging anomaly–free $U(1)_{B-L}$ . . . 2350

12.8 Antimatter in the IQR/Tantrakyma Standard Model . . . 2356
12.9 Antimatter from Complex Reps, Causality, Positivity, and Family Holonomy . 2359
12.9.1 Complex Representations of the Internal Connection . . . 2359
12.9.2 Relativistic Causality + Positivity ⇒ CPT and Conjugate Poles . . . 2362
12.9.3 Family Fibre Holonomy is Neutral but Conjugates under C . . . 2364
12.9.4 Consequences and Canonical Cases . . . 2364
12.10 Antimatter as a Duality Theorem . . . 2368
12.10.1 Categorical Duality on Matter (Algebraic, Kinematic, and Cohomological Faces) . . . 2368
12.10.2 Antimatter as a Duality Theorem . . . 2370
12.10.3 Operational Corollaries . . . 2371
12.10.4 Diagnostic realized reference configuration Structure that Forces Pairing (Spectral/Cohomological Face) . . . 2373
12.10.5 Typed Antiparticles as a Corollary of Duality . . . 2377
12.10.6 Operational Diagnostics . . . 2380
12.11 The Antimatter Theorem and Supersymmetry . . . 2384
12.11.1 Supersymmetric Extension of Antimatter Duality . . . 2386
12.12 The Standard Model with Gravity . . . 2390

Preface: A Scientist's Invitation to Dare to Dream

Acknowledgements

I wish it to be known and understood from the outset that the treatise presented herein lays no claim to original invention or discovery. None of the philosophies, principles, mathematics, or physical insights are solely of my own making. My role has been that of a humble and devoted student, learning from the luminous expositions of the great teachers of all ages — from the sages of Eastern and Western traditions spanning more than two millennia, to the brilliant minds of our own time. If I may be so bold as to claim any contribution, it is a modest one: an effort of translation and synthesis, seeking to render the timeless wisdom of ancient thought into the rigorous language of modern mathematics, and to weave the insights of the greatest thinkers into a single, coherent framework. Any understanding I may have achieved is due entirely to the generosity of those who dedicated their lives to creating the vast commentaries and discoveries that illuminate these profound subjects.

This acknowledgement is an essential part of the work itself, for the Interdependent Quantum Reality framework draws as deeply from the philosophical and human heritage of thought as it does from the mathematics that gives it form. That heritage is broad and without sectarian preference: the antecedent ideas appear in many streams of human inquiry — from the metaphysical investigations of Aristotle and Aquinas, to the subtle dialectics of Buddhist Madhyamaka philosophy, to the reflections of modern physicists and cosmologists. In drawing upon them, I have given none precedence over another, but have sought only to honour ideas that have endured because they speak to something universal, and all are valued equally as part of the shared legacy of humanity's search for truth. My aim has been to respect these enduring insights, and to show how they may now be expressed in precise mathematical form.

This work, therefore, is not a monument to novelty, but a pilgrimage — an offering of deep homage and reverence to the wisdom of the ages. It is an attempt to reveal the insights of those philosophical and intellectual giants, to share their brilliance so that we, together, may clear the dust from our eyes and see a little further by the light of their cumulative genius. It is with heartfelt gratitude to the Buddhas, Gurus, Scientists, and Philosophers of all ages that this work is offered. It is also a tribute to the imaginative spirit of science fiction novelists, and to my own primary school, high school, and university teachers. This treatise exists only because of their dedication and achievements. My deepest thanks go to my family, who have unfailingly supported me in my endeavors, and to my friends, who have

shared in this journey. *The work presented here is thus offered in reverence and devotion — for the welfare and joy of all the world.*

The Cosmic Quantum Dream

My own intellectual journey began with a simple yet profound encounter in the final year of primary school. I came across a science textbook, the name and author of which are now long lost to memory, but whose intellectual impact has remained with me ever since. In its pages, I found a marvelous description of the double-slit experiment, which sought to explain that light was possessed of a seemingly contradictory nature: it was both a particle and a wave. The concept of this wave-particle duality captivated my young mind, and I found myself lost in the vast and wondrous landscape of the imagination that it provoked—a landscape where the rigid certainties of the classical world dissolved into a shimmering reality of quantum potentia.

In parallel with this burgeoning scientific curiosity, a serendipitous loan from my local suburban library introduced me to the literary dimension of cosmic scale. The book was The Foundation Trilogy by the grandmaster of science fiction, Isaac Asimov, and it proved to be the progenitor of a lifelong passion for the genre. I was completely consumed by the cosmic breadth of its narrative, a story of such compelling power that I could rarely bring myself to put it down. Its allure was such that I would often find myself poring over its pages by torchlight, hidden beneath my blankets long after I was meant to be asleep, or at other times, by the faint, borrowed light of a distant street lamp.

By a happy coincidence of fortune, that same year saw the release of Star Wars: Return of the Jedi on VHS. I recall with great clarity a particular Friday afternoon when my primary school, in a welcome departure from its customary screening of Looney Tunes cartoons, presented the film to the grades 5 and 6 classes. The experience was transformative. I remember returning home that evening with an urgent desire to continue my journey through Asimov's literary galaxy, my imagination now alight with visions from two distinct yet harmonious universes. It was in those formative moments that I became a lifelong admirer of the grand tradition of science fiction, a passion that has continued to fuel my intellectual and philosophical inquiries ever since.

This early triad of influences—the quantum enigma of the double-slit experiment, the epic literary scope of the *Foundation Trilogy*, and the mythic grandeur of *Star Wars*—exerted a profound and lasting influence upon my intellectual aspirations. Indeed, I believe they provided the essential fuel for my subsequent academic pursuits in high school. It was here, amidst the structured world of secondary education, that another formative element was introduced, one that would later become central to my worldview: the conception of the universe as a grand, cosmic symphony.

During these years, I undertook the study of the clarinet, a pursuit in which I found unexpected joy and success, so much so that I was invited to join the high school band. The discipline required was demanding; I recall long evenings of rehearsal, stretching from the end of the school day late into the night. Yet, it was through this immersive experience in the collaborative harmony of the band that I began to perceive the world through a new sensory modality. Music, it seemed, endowed me with the ability to apprehend mathematics

in a different light—revealing its abstract structures as a dynamic and beautiful rhythm that transcended mere static rules and invited participation and experience.

My time in high school was one of rich intellectual discovery, a period during which I found myself particularly drawn to the elegant formalisms of science and mathematics, as well as to the distinct mode of cultural expression offered by the study of the Italian language. My dedicated application to these disciplines was met with consistent academic success, for which I remain grateful. This period of study culminated in the great fortune of being awarded a scholarship to the National Science Summer School—an immersive two-week program held in the nation's capital, which included a residence at the university.

It was here, however, that my intellectual path found its definitive vector. A visit to the radio telescope facility at Tidbinbilla, with its vast dishes aimed at the silent cosmos, and to the Australian National University's experimental Tokamak reactor, a testament to humanity's quest to harness the power of the stars, had a profound and orienting influence upon the direction of my future inquiries. These encounters with the grand instruments of scientific exploration solidified a nascent aspiration to understand the fundamental principles that govern the universe on both its grandest and most intimate scales.

My academic path continued to a university of great standing, where I first enrolled as a student of engineering. While I found a certain fluency in the language of engineering mathematics—at one point completing an examination on partial differential equations with a swiftness that surprised even myself—I felt a growing sense of disillusionment. The vicissitudes of life and a persistent longing for something more profound gradually revealed that the pragmatic focus of the discipline, however valuable, could not address the fundamental questions that had taken root in my mind. In my final year, I made the decision to change course, leaving engineering to pursue a Bachelor of Science with a double major in both pure and applied mathematics. It was here, particularly in an Honours Analysis class to which I was fortunately invited, that I gained a deeper appreciation for the abstract architecture of Hilbert spaces, a concept so central to the quantum view of the world. Throughout these undergraduate years, my formal studies were complemented by a voracious and undisciplined appetite for the works of the great thinkers in mathematics, physics, and philosophy—all consumed outside the structured curriculum in a private search for answers to the deep and unsettling questions about the nature of reality.

After graduating, I pursued a Master's Degree in Information Technology, focusing on Artificial Intelligence, where I wrote a thesis on Swarm Intelligence and had the honour of co-authoring a paper on self-organizing intelligent systems. A subsequent doctoral program was, alas, abandoned due to the pressing demands of life, in favour of a career in software engineering. This professional detour, along with my later experiences in machine learning and big data, afforded me the unexpected opportunity to become a lecturer and unit designer at a business school, where I helped create a Master of Business Analytics program. I found great satisfaction in both the craft of software engineering and the art of teaching. However, the foundational question concerning the nature of our cosmos, of our reality, remained unanswered, and this slowly grew into a persistent intellectual disquiet.

Did I ever abandon the hope that I would finally synthesize these disparate threads of knowledge to answer this mystery? No. The aspiration that I had as a primary school pupil, the formative experiences in high school, and the theoretical ideas that began to take shape during university never truly receded, always remaining prescient in the back of my

mind. Throughout my professional career, I continued my private attempts to reconcile my understanding of philosophy, mathematics, and physics, never giving up the hope that I would one day develop the clarity to put all the pieces I had learned over many decades into a single, coherent whole. The knowledge presented in this treatise is the culmination of those years of searching for a way to mathematically articulate what I understood in my heart to be true, an understanding I now wish to share with my fellow students of science so that we may *dare to dream*.

With the gratitude and origins of this work now spoken, we may turn to the dream that drives it — a dream that takes shape as the direct consequence of the successful unification of General Relativity and Quantum Mechanics. But what form does such a dream take? This treatise achieves that synthesis by showing that the long-standing conflict between the two great pillars of physics dissolves once we relinquish the assumption that spacetime is fundamental, an idea that resonates with contemporary research suggesting geometry is woven from the fabric of quantum entanglement [1, 2]. The grand visions of interstellar travel and cosmic connection, so vividly imagined in the science fiction that shaped my youth, thus cease to be idle fantasy; they become direct, answerable questions posed to the unified theory itself.

The mechanism for this unification is distilled into a single, foundational equation:

$$\underbrace{\bar{\Sigma}_{\mu\nu}(x)}_{\text{emergent chronogeometry}} \quad = \quad \underbrace{\left\langle \mathring{\boldsymbol{\Psi}} \,\middle|\, \hat{\Sigma}_{\mu\nu}(x) \,\middle|\, \mathring{\boldsymbol{\Psi}} \right\rangle}_{\text{quantum expectation}}$$

This expression—the **Chronogeometric tensor** $\bar{\Sigma}_{\mu\nu}(x)$ (Definition 5.25)—is the precise bridge between classical and quantum descriptions [3, 4]. It asserts that the curved spacetime of General Relativity is not an independent backdrop, but the macroscopic statistical average of a deeper quantum structure.

This emergent geometry arises from two fundamental quantum ingredients:

1. the *Quantum Holo-State* $\left|\mathring{\boldsymbol{\Psi}}\right\rangle$ (Definition 1.27), encoding the total relational state of the universe [3]; and

2. the *Chronogeometric Operator* $\hat{\Sigma}_{\mu\nu}(x)$ (Definition 5.26), defined by

$$\hat{\Sigma}_{\mu\nu}(x) \;:=\; \hat{g}_{\mu\nu}(x) \;+\; \hat{t}_{\mu\nu}(x),$$

   where $\hat{g}_{\mu\nu}(x)$ generates the geometric structure and $\hat{t}_{\mu\nu}(x)$ captures the temporal phase-flow of quantum phenomena [4, 5]. (In the main text we specify $\hat{t}_{\mu\nu}$ as a *symmetric*, covariant operator with a common invariant core and give its GNS representation at each PQS; see Section 11.5.4.)

The full dynamical content is expressed by the *Chronogeometric Einstein Equations* (Section 11.5.4):

$$\bar{G}_{\mu\nu}[\bar{\Sigma}] \;+\; \Lambda\,\bar{\Sigma}_{\mu\nu} \;=\; \kappa\,\bar{T}^{\text{total}}_{\mu\nu}(x).$$

Here and throughout, indices are raised and lowered using $\bar{\Sigma}_{\mu\nu}$ (so the source is written covariantly as $\bar{T}^{\text{total}}_{\mu\nu}$), and we restrict attention to histories for which $\nabla^{\mu}\bar{\Sigma}_{\mu\nu} = 0$ with respect

to the torsion-free connection compatible with $\bar{\Sigma}$; the contracted Bianchi identity then yields $\nabla^{\mu}\bar{T}^{\text{total}}_{\mu\nu} = 0$. In decohered regimes $\bar{\Sigma}_{\mu\nu} \to \bar{g}_{\mu\nu}$, so the Λ term reduces to its familiar GR form and the equation recovers Einstein's law in outward appearance [6, 7].

On the geometric side, curvature is built from the unified chronogeometric field $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$, so spacetime responds not only to spatial distinguishability ($\bar{g}$) but also to the quantum flow of phase ($\bar{t}$) [8, 3, 9]. On the source side, $\bar{T}^{\text{total}}_{\mu\nu}$ is the expectation-valued stress–energy combining the material/radiative *Tantrakyma* sector with the energy associated to the geometric field itself (*Gaiamiti*) [10, 11, 12, 13]. In this reading, the classical geometry we observe is the expectation of the unified operator $\hat{\Sigma}_{\mu\nu}$ in the holo-state—a property *of* the quantum state rather than a pre-existing stage [10, 11, 8, 3, 14].

With the imaginative impetus now fixed, we turn from recollection to construction. The pages that follow advance a single programme: to translate the images above into invariants and the questions into operators. *Part I: The Foundations* introduces the primitive grammar and logic of the framework—the Fourfold Dialectic Algebra and the Primordial Quantum Singularity—within which the central objects already invoked receive their formal dress: the Quantum Holo-State, the Chronogeometric Operator, and the unified chronogeometric tensor $\bar{\Sigma}_{\mu\nu}$ (see Definitions 1.27, 5.25 and 5.26). With these definitions in place, the narrative becomes calculational and the "cosmic dream" acquires equations. We begin, accordingly, with the alphabet and generating symmetries of the theory.

Part I: The Foundations

Chapter 1: The Fourfold Algebra and the Singularity

The chapter proposes a four-vertex "prism" for thinking—Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry—where the immanent base (the first three) encodes relational dynamics and the apex (Holosymmetry) governs the whole, so that "symmetry" in its fullest sense is the indivisible fourfold rather than a single invariance [15, 16, 17, 18]. This prism is operationalised as a Fourfold Dialectic Algebra (Section 1.2.8) whose atomic unit is the *Tetralemma of Algebra*, $\mathring{\mathbf{\Lambda}} = \langle \mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh} \rangle$, closed and indecomposable (Sections 1.2.5, 2.3 and 3.8 and Definition 1.5). "The Quantum Revelation: A Tetralemmatic Journey" then reads the passage from superposition to classical fact as a traversal of this prism [19, 20]: unmeasured potentialities inhabit corners beyond classical bivalence, while measurement and decoherence "close the cycle," and truth becomes a graded warrant given by Born valuation with a concrete "prism protocol" $\rho \mapsto (v_T, v_A, v_S, v_H)$ (Sections 1.2.8 and 1.2.9 and eq. (3.36)) [21, 22, 23, 24, 25, 26]; when interrogations commute, Non-Contradiction and Excluded Middle reappear as theorems rather than axioms, and in a Gelfand–Naimark–Segal (GNS) realisation these valuations become ordinary expectations on the emergent Hilbert space (Sections 1.2.8 and 1.4.2) [27, 28, 29, 30].

A scale-free Axiom of Duality stabilises the picture: a functorial $\mathbf{D}_{\mathcal{C}}$ acts coherently on states, formulas, and rules, keeping the tetralemma closed under admissible re-indexings [27, 28, 29, 31, 32] (Proposition 1.12); concretely, each Primordial Quantum Singularity (PQS) $\mathfrak{B}_x$ bears a four-generator *-algebra $\mathcal{A}_x^{(4)}$ congruent to these modalities, providing the grammar later spoken by the Algebra of Observables and uttered via GNS into measurable tests [30, 22]

(Definitions 1.16 and 1.32). Historically, the programme is framed between Aristotle's forging of a defensible *thesis* and the fortress of non-contradiction (Section 1.1.6) and the Indian discipline of *vāda*, where a *pratijñā* proceeds by regulated, five-membered proof toward *tattva-nirṇaya* [18, 33, 34] (Section 1.1.7); conceptually, these strands feed the final outlook: four guiding principles elevate dependent origination into generative physics [17, 35, 16]—via an $\hat{\Omega}$-Continuum of Primordial Quantum Singularities and a single, non-factorizable Quantum Holo-State whose GNS realisation selects and builds its arena [30, 20]—yielding Gaiamiti (chronogeometry/gravity) and Tantrakyma (the Standard-Model façade) as two effective, jointly constrained sectors [36, 37, 38, 39], with emergent chronogeometry responding to total quantum stress–energy and thus closing the loop between coherence, curvature, and matter [40, 41, 42, 43, 44, 45] (Sections 1.1.1 and 4.1).

From Blueprint to Actualization. Chapter 1 presents the *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16) as an *a priori* blueprint of admissible modes of assertion—**Symmetry** (Thesis Th), **Antisymmetry** (Antithesis AntiTh), **Parasymmetry** (Synthesis SynTh), **Holosymmetry** (Holothesis HoloTh)—*in the spirit of tetralemmatic logics and their modern analyses* [17, 18, 15, 16], and then shows how the Gelfand–Naimark–Segal (GNS) construction (Section 1.4.2) turns those logical forms into concrete quantum tests and expectations [30, 29, 22] (Definition 1.18) within an emergent Hilbert arena [20]. In short: Dialectic provides the rules of construction; GNS performs the construction.

Three-tiered emergence pipeline. (1) *Ontological (generative logic):* at each PQS $\mathfrak{B}_x$ (Section 2.3), the Fourfold Dialectic furnishes primitive "ringed" ontological labels (cf. Remark 1.22) [35, 15, 16]; (2) *Algebraic (operational vocabulary):* the C^*-algebra $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32) is generated by geometric (Gaiamiti), matter (Tantrakyma), and symmetry fields [30, 36, 37]; (3) *Physical (emergent representation):* a GNS state $\omega^{\mathring{\mathbf{\Psi}}}$ yields $(\pi_{\mathring{\mathbf{\Psi}}}, \mathcal{H}_{\mathrm{em}}, |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle)$ (Section 1.4.2) [30, 29, 20], in which all corner-valuations become ordinary expectations [21, 22] (Definition 1.18 and Section 4.1).

The Fourfold Dialectic Algebra (ontological layer)

Born semantics and facets. At each $\mathfrak{B}_x$, the four modes act as testable facets with Born-valued semantics (Section 1.2.9 and Definition 1.18). Thesis/Antithesis probe a distinguished axis; Synthesis interrogates coherent coexistence on that axis; Holothesis is a controlled, interferometric meta-probe of global implementation. Truth is the Born value $v(\rho; P) = \mathrm{Tr}(P\rho)$, so facets need not be mutually exclusive; they register complementary warrant-degrees in a single preparation ρ.

Duality and status-compatibility. A context-indexed duality $\mathbf{D}_{\mathcal{C}}$ (an involution) exchanges Thesis and Antithesis while fixing Synthesis and Holothesis (Definition 1.16 and Proposition 1.12):

$$\begin{aligned} \Delta_{\mathcal{C}}(\mathsf{Th}) = \mathsf{AntiTh}, \quad \Delta_{\mathcal{C}}(\mathsf{AntiTh}) = \mathsf{Th}, \\ \Delta_{\mathcal{C}}(\mathsf{SynTh}) = \mathsf{SynTh}, \quad \Delta_{\mathcal{C}}(\mathsf{HoloTh}) = \mathsf{HoloTh}, \\ \mathbf{D}_{\mathcal{C}}^2 = \mathrm{Id}, \end{aligned}$$

with status-compatibility

$$\mathsf{Status}_{\mathcal{C}}(\varphi,\lambda)=X \;\Rightarrow\; \mathsf{Status}_{\mathcal{C}}(\varphi^{\mathbf{D}},\lambda)=\Delta_{\mathcal{C}}(X),$$

and inapplicability invariant under dualization (Section 3.8).

Object-level instance. If $|\mathring{\mathbf{0}}\rangle$ is any primitive ontological state, define $|\mathring{\mathbf{1}}\rangle \coloneqq \mathbf{D}_{\mathcal{C}}(|\mathring{\mathbf{0}}\rangle)$ (Definition 1.16). Then

$$|\mathring{\mathbf{0}}\rangle \leftrightarrow |\mathring{\mathbf{1}}\rangle, \qquad \mathbf{D}_{\mathcal{C}}(|\mathring{\mathbf{1}}\rangle)=|\mathring{\mathbf{0}}\rangle,$$

so the dyad is semantically primary (Remark 1.22).

Self-similarity and closure. Under any admissible re-indexing $\mathcal{C}\to\mathcal{C}'$ that preserves dependent origination, there exists a unique $\mathbf{D}_{\mathcal{C}'}$ with

$$F\circ\mathbf{D}_{\mathcal{C}}=\mathbf{D}_{\mathcal{C}'}\circ F,$$

hence $\{\mathsf{Th},\mathsf{AntiTh},\mathsf{SynTh},\mathsf{HoloTh}\}$ is closed and pointwise fixed under repeated dualization (Proposition 1.12).

Parasymmetry (Synthesis). In the distinguished $(0,1)$-sector, Synthesis is the normalized superposition

$$\tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle+|\mathring{\mathbf{1}}\rangle\big).$$

The projector P_{para} isolates this coherent mode with Born valuation $v_{\text{S}}(\rho)=\text{Tr}(P_{\text{para}}\rho)$ (Section 1.2.9 and Definition 1.18). The pair $\{P_{\text{para}},P_{\text{antipara}}\}$ forms an orthogonal, complete resolution of the $(0,1)$-sector, guaranteeing basis-coherence with Thesis/Antithesis. Beyond a single locus, Synthesis becomes *relation*: bipartitely a Bell-like entangled mode with projector $P^{(xx')}_{\text{para}}$; multipartitely a W-like $|\Psi^{(n)}_{\text{para}}\rangle$ with global projector $P^{(x_1\ldots x_n)}_{\text{para}}$, exhibiting genuine multipartite entanglement and permutation symmetry (Section 1.2.8).

Holosymmetry (Holothesis). Holothesis formalizes typed *inapplicability* of the base existential polarity and its invariance under dualization (Section 3.8). Operationally, a holosymmetric control $\mathbf{U}_{\text{ctrl}}$ branches dual registers under two lifted path-laws, recombines, and reads out on the control—interrogating *architecture* rather than local alternatives (Section 2.3). The Holothesis effect $E^{(\mathbf{a}\to\mathbf{b})}_{\text{Holo}}$ yields the Born value

$$v_{\text{H}}(\rho)=\text{Tr}\Big(E^{(\mathbf{a}\to\mathbf{b})}_{\text{Holo}}\,\rho\Big)$$

as defined in (eq. (3.36)).

The "Prism for Discourse" and Born semantics

Quantitative facets. Logic is treated as diagnostic interrogation—a prism that refracts discourse into four facets, each returning a quantitative degree of warrant $v\in[0,1]$ (Section 1.2.8). In the formal core, each facet $\square\in\{\text{T},\text{A},\text{S},\text{H}\}$ corresponds to an effect $E_{\square}$ with

$$v_{\square}(\rho)=\text{Tr}(E_{\square}\rho), \qquad P_T=|e_1\rangle\langle e_1|, \quad P_A=|e_2\rangle\langle e_2| \;\text{ on the } (0,1)\text{-sector},$$

as specified by the Born semantics of the fourfold effects (Section 1.2.9 and Definition 1.18).

Classical logic as a special slice. On the $(0,1)$-sector,

$$P_T + P_A = P_{(0,1)} \;\Rightarrow\; v_T + v_A = 1 \quad \text{(Excluded Middle)}.$$

In the commuting/decohered limit, $P_T P_A = 0$ and SynTh carries no independent signal (Non-Contradiction); the fourfold prism collapses to the classical fortress (Section 1.2.8).

Reading a discourse. Given ρ, perform complementary interrogations:

$$(v_T(\rho), v_A(\rho)), \qquad v_S(\rho) = \mathrm{Tr}(P_{\mathrm{para}}\rho), \qquad v_H(\rho) = \mathrm{Tr}(E^{(\mathbf{a}\to\mathbf{b})}_{\mathrm{Holo}}\rho).$$

These are not mutually reducible and resolve distinct structural aspects (Section 1.2.8 and eq. (3.36)).

Algebraic and GNS layers (actualization)

Algebra of Observables $\mathcal{A}(\mathcal{C}_d)$. $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32) is the C^*-algebra generated (per locus $\vec{r} \in \mathcal{C}_d$) by: Gaiamiti geometric fields $\{\hat{\mathbf{\Phi}}_{\vec{r}}\}$, Tantrakyma matter-content fields $\{\hat{\mathbf{\Theta}}_{\vec{r}}\}$, and duality/symmetry generators $\{\hat{\mathbf{\Lambda}}_{\vec{r}}\}$ (Definition 1.16). It is the smallest norm-closed, involutive algebra containing finite linear combinations, products, and adjoints of these generators (Definition 1.32).

GNS construction of the Quantum Holo-State. From the state functional $\omega^{\mathring{\mathbf{\Psi}}}$ one constructs the cyclic triple (Section 1.4.2)

$$(\pi_{\mathring{\mathbf{\Psi}}},\ \mathcal{H}_{\mathring{\mathbf{\Psi}}} = \mathcal{H}_{\mathrm{em}},\ |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle).$$

The ontological symbol $|\mathring{\mathbf{\Psi}}\rangle$ is thereby represented by the cyclic vector $|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle$, and for any effect E,

$$\omega^{\mathring{\mathbf{\Psi}}}(E) = \langle\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}|\pi_{\mathring{\mathbf{\Psi}}}(E)|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle, \qquad v(\rho; E) = \mathrm{Tr}\Big(\rho\,\pi_{\mathring{\mathbf{\Psi}}}(E)\Big),$$

where dialectic valuations coincide with Born semantics (Definition 1.18). The GNS triple is unique up to unitary equivalence (Section 1.4.2).

Self-generating arena (background independence). The state not only fixes expectations; it generates its own Hilbert space and inner product (Sections 1.4.2 and 4.1 and Proposition 1.30):

$$\Big\langle \pi(A)|\Omega\,,\ \pi(B)|\Omega\Big\rangle = \omega^{\mathring{\mathbf{\Psi}}}(A^\dagger B).$$

Thus "the state defines the space that contains it."

The Quantum Holo-State and scale-bridging roles

Local kinematics and global geometry. $\overset{\circ}{\boldsymbol{\Psi}}$ fixes the *local* inner product on each modal Hilbert space $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ via the Fourfold Inter-Modal Correlator (Proposition 1.30):

$$\langle \psi_1 | \psi_2 \rangle_{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}} := \lim_{x' \to x} \langle \overset{\circ}{\boldsymbol{\Psi}} \mid \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \mid \overset{\circ}{\boldsymbol{\Psi}} \rangle,$$

and, complementarily, determines the *global* emergent spacetime manifold $\mathcal{M}_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}$. A single Holo-State thus provides the defining context for both "arena" and "actors."

PQSs, the $\hat{\Omega}$-continuum, and $\mathcal{X}_q$

Primordial loci and configuration space. A Primordial Quantum Singularity $\mathfrak{B}_{\vec{r}}$ (Section 2.3) is an elementary operator-valued locus whose definitive quantum nature is the Quantum Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ (Section 1.4.2 and Proposition 1.30). The framework replaces a fixed $\mathbb{C}^2$ qubit with a field-embedded, duality-governed, operator-valued singularity as the apex of causality (Definition 1.32 and Proposition 1.12). The tension between a universal state and inherently local operators motivates a *quantum configuration space* $\mathcal{X}_q$ (Section 4.1): distinguishable loci arise by relational crystallization—equivalence classes of PQS constituents in the $\hat{\Omega}$-Continuum (Section 1.1.1).

Putting it together: from logic to lab

Diagrammatic reading. A "from logic to lab" diagram (fig. 1.2) maps each corner's ontological label → realized effect → Born truth → concrete measurement, all grounded in the GNS/emergent layer. This ties the three tiers tightly: logical labels at the top, algebraic effects in the middle, and the emergent representation (GNS) at the base, where Born valuations become standard expectations on $\mathcal{H}_{\text{em}}$.

Minimal takeaway.

- The Dialectic Algebra $(\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh})$ with $\mathbf{D}_{\mathcal{C}}$ and $\Delta_{\mathcal{C}}$ is an ontological blueprint realized as effects with Born-valued truth (Definitions 1.16 and 1.18 and Proposition 1.12).
- SynTh detects *coherent coexistence*: locally via $\frac{1}{\sqrt{2}}\left(|\overset{\circ}{\mathbf{0}}\rangle \pm |\overset{\circ}{\mathbf{1}}\rangle\right)$, globally via Bell/W-like relations (Sections 1.2.8 and 1.2.9).
- HoloTh interrogates *architecture* by controlled holosymmetric evolutions; its status includes typed inapplicability conditions invariant under dualization (Sections 2.3 and 3.8 and eq. (3.36)).
- $\mathcal{A}(\mathcal{C}_d)$ + GNS with $\omega^{\overset{\circ}{\boldsymbol{\Psi}}}$ produce $(\pi_{\overset{\circ}{\boldsymbol{\Psi}}}, \mathcal{H}_{\text{em}}, |\Omega_{\omega^{\overset{\circ}{\boldsymbol{\Psi}}}}\rangle)$, turning all valuations into standard quantum expectations (unique up to unitary equivalence) (Definitions 1.18 and 1.32 and Section 1.4.2).

- The Holo-State unifies scales: locally, it fixes inner products of modal fibres; globally, it shapes the emergent spacetime $\mathcal{M}_{\text{em}}^{(\overset{\circ}{\mathbf{\Psi}})}$ (Proposition 1.30 and Section 4.1).

Compact pipeline (ontology ⇒ laboratory):

$$\begin{aligned} &\text{Fourfold Dialectic (ontology) } (\textit{Definition } 1.16) \\ &\Rightarrow\ \mathcal{A}(\mathcal{C}_d) \text{ (operational language) } (\textit{Definition } 1.32) \\ &\Rightarrow\ |\overset{\circ}{\mathbf{\Psi}}\rangle \xrightarrow{\text{GNS}} (\mathcal{H}_{\text{em}}, \pi_{\overset{\circ}{\mathbf{\Psi}}}) \ (\textit{Section } 1.4.2) \end{aligned}$$

This is exactly the *Blueprint* → *Actualization* logic that Chapter 1 establishes, with duality-driven self-similarity (Proposition 1.12) and a Holo-State that simultaneously selects spacetime (Section 4.1) and fixes local quantum kinematics (Proposition 1.30).

Chapter 2: The Fourfold Symmetry

Chapter 2 operationalises the Fourfold programme by giving it a concrete quantum realisation [22, 29]. Each Primordial Quantum Singularity (PQS) carries a modal fibre $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ in which Thesis/Symmetry and Antithesis/Antisymmetry are realised as $|e_1\rangle, |e_2\rangle$ spanning the $(0,1)$-sector, with generic states constrained accordingly (Section 2.1 and Definition 2.1) [30, 20]. The local involutive duality $D^{(\mathfrak{B}_x)}$ swaps these modes and lifts diagonally to a global involution $\hat{D}_{\text{PQS}}^{(n)} = \bigotimes_i D^{(\mathfrak{B}_{x_i})}$, encoding a fibrewise Thesis–Antithesis exchange across an n-site configuration (Definition 2.7, Section 2.1.3, and eq. (2.12)) [27, 28, 29]. Parasymmetry (Synthesis) is then given a precise operator meaning: locally by working within the $(0,1)$-sector, and globally via rank-1 projectors onto bipartite entangled states that realise synthesis and its orthogonal dissonance (Section 2.2, Definition 2.23, and eq. (2.58)) [22]. This extends to the multipartite W-state together with a canonically orthogonalised anti-parasymmetric complement, yielding a complete two-dimensional "coherence plane" in the single-excitation sector (Definitions 2.33 and 2.37 and eq. (2.59)) [22, 29]. On this plane, orthogonality, normalization, and span-complementarity are proved explicitly, resolving parity subtleties for odd n.

Layered parasymmetric dynamics. Dynamics are organised in layers [22, 29]. Pairwise and modal-class generators distinguish and drive transitions between parasymmetric synthesis and anti-parasymmetric dissonance [46, 30]; from these, several families of unitaries are built: (i) block-factorised evolutions where disjoint regions follow local/pairwise/global rules independently [22]; (ii) "zonal" evolutions with an active dynamical region and a static complement [47, 48]; and (iii) fully coupled, graph-encoded global evolutions that are not factorisable [49, 39]. A "unified" generator then aggregates local, pairwise, multipartite, and excitation-exchange terms, producing the most general parasymmetric unitary permitted by the scheme (Definitions 2.42, 2.43, 2.54, 2.59, 2.66, 2.70 and 2.78 and eq. (2.56)) [30, 29].

Holosymmetry as interferential higher-order synthesis. Finally, the chapter introduces holosymmetry as a controlled superposition of entire evolutionary histories [22, 23, 24, 25, 26]. Two disjoint PQS registers A, B are coupled to a control qubit whose computational basis toggles which register undergoes a globally coupled vs. a decoupled parasymmetric evolution; in superposition, these mutually exclusive assignments interfere [22, 47, 48]. Lifted operators $U_{\cdot}^{(A)}, U_{\cdot}^{(B)}$ act selectively on registers, and a controlled holosymmetric unitary $\mathbf{U}_{\text{ctrl}}$ enacts path-conditioned evolutions on the full holosymmetric Hilbert space $\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}$, whose dimension 2^{4n+1} reflects the exponential richness of the dual-register construction (Sections 2.3.2 and 2.4.1, Definitions 2.102, 2.103, 2.114 and 2.123, and eq. (2.75)) [22, 30, 29]. Holosymmetry thus appears as higher-order synthesis: interference between different ways the universe may organise its internal coherence [23, 24, 25, 20, 49].

Parasymmetry, Global Duality, and Holosymmetric Interferometry

Local and global parasymmetric sectors. Chapter 2 turns the ontological blueprint for Synthesis/Parasymmetry into concrete Hilbert-space objects and gates. Locally, at each PQS $\mathfrak{B}_{x_i}$, the parasymmetric sector is the distinguished $(0,1)$-modal slice inside the modal fiber $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_{x_i})} \cong \mathbb{C}^4$,

$$\mathcal{H}_{(0,1)}^{(x_i)} = \text{span}\{|\mathring{\mathbf{0}}\rangle_{x_i}, |\mathring{\mathbf{1}}\rangle_{x_i}\} \subset \mathbb{C}^4, \qquad |\mathring{\mathbf{0}}\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad |\mathring{\mathbf{1}}\rangle = \begin{pmatrix}0\\1\\0\\0\end{pmatrix},$$

and for n loci the global parasymmetric modal space is $(\mathbb{C}^2)^{\otimes n}$ with $\dim = 2^n$ (Definition 2.16). Within the $(0,1)$-sector, the logical projectors $P_T = |e_1\rangle\langle e_1|$ and $P_A = |e_2\rangle\langle e_2|$ carry Born valuations $v_{\text{Thesis}}(\rho) = \text{Tr}(P_T\rho)$, $v_{\text{Antithesis}}(\rho) = \text{Tr}(P_A\rho)$ exactly as in the prism semantics of Chapter 1 (Definition 1.18).

Parasymmetric projectors and valuations. The local parasymmetric axis is isolated by $P_{\text{para}}^{(x)}$, with $\{P_{\text{para}}^{(x)}, P_{\text{antipara}}^{(x)}\}$ an orthogonal, complete resolution of the $(0,1)$-sector; gauge variants (local phases, site relabelings) are operationally equivalent (Section 2.2.1 and Definition 2.17). Operationally, one probes Parasymmetry by rotating into the Σ_x basis and projecting with $P_{\text{para}}^{(x)}$ (cf. eqs. (2.58) and (2.59)).

Relational Parasymmetry (entanglement). Bipartitely, Parasymmetry "becomes entanglement." The Bell-like state

$$|\Psi_{\text{para}}\rangle_{xx'} = \tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle_x |\mathring{\mathbf{1}}\rangle_{x'} + |\mathring{\mathbf{1}}\rangle_x |\mathring{\mathbf{0}}\rangle_{x'}\big),$$

with projector $P_{\text{para}}^{(xx')} = |\Psi_{\text{para}}\rangle_{xx'}\langle\Psi_{\text{para}}|_{xx'}$, realizes distributed co-alignment that belongs to neither locus individually (Section 2.2.3). Multipartitely, $P_{\text{para}}^{(x_1\ldots x_n)}$ detects W-like global modes with genuine multipartite entanglement and permutation symmetry (cf. eq. (2.59)).

Unified parasymmetric generator. Dynamics are generated by a single parasymmetric unitary

$$U_G^{(\odot)} = \exp\Big(i\,\hat{F}_{\text{para}}^{(\odot)}\Big),$$

where $\hat{F}_{\text{para}}^{(\odot)}$ merges local coherence, pair projectors, global modal-class terms, and inter-site exchange $\sum_{i\neq j} J_{ij}\Big(\hat{\sigma}_{x_i}^{(+)}\hat{\sigma}_{x_j}^{(-)} + \text{h.c.}\Big)$; this yields the most general parasymmetric dynamics admissible in the framework (eq. (2.56)).

Global involutive duality. At scale, the global involutive duality operator acts fiberwise across an n-site configuration,

$$\hat{D}_{\text{PQS}}^{(n)} := \bigotimes_{i=1}^{n} D^{(\mathfrak{B}_{x_i})},$$

coherently exchanging Symmetry $\leftrightarrow$ Antisymmetry on each modal fiber and defining a canonical involutive automorphism of the modal Hilbert bundle (eq. (2.12)).

Holosymmetric gates and interferometry. Holosymmetry is operationalized via controlled/interferometric unitaries that compare full PQS-register pathways:

- *Controlled holosymmetric operator* (Definition 2.114 and eq. (2.75)):

  $$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} \;+\; |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

  block-diagonal in the control computational basis with blocks $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$, $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ (Section 2.3.2).

- *Hadamard-conjugated form* (Section 2.3.2):

  $$\mathbf{U}_{\text{Had}} := (H_c \otimes I_{\text{RR}})\,\mathbf{U}_{\text{ctrl}}\,(H_c \otimes I_{\text{RR}}) = |+\rangle\langle+|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |-\rangle\langle-|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}.$$

- *Readout gate* (Section 2.4.1): $\mathbf{U}_{\text{read}} = (U_c^{\text{read}} \otimes I_{\text{RR}})$ with $U_c^{\text{read}} \in \text{SU}(2)$; choosing $U_c^{\text{read}} = H$ projects into the symmetric/antisymmetric basis.

- *Symmetric interferometer* (Definition 2.123):

  $$\mathbf{U}_{\text{holo}}^{(\text{sym})} := \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}},$$

  acting on $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$.

- *Asymmetric generalization* (Definition 2.123): arbitrary preparation (α, β) and readout (γ, δ) bases probe off-diagonal modal structure and "holosymmetric curvature."

Operational picture and invariants. (a) Local Parasymmetry is a repeatable "test & filter" along the Σ_x axis; (b) bipartite and n-partite Parasymmetry are entangled co-alignments detected by $P_{\text{para}}^{(xx')}$ and $P_{\text{para}}^{(x_1\ldots x_n)}$ (cf. eqs. (2.58) and (2.59)); and (c) holosymmetric interferometers $(\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{read}})$ elevate *architecture* to an observable by reading interference on the control. Dynamics that preserve global Parasymmetry are precisely those unitaries U that leave $P_{\text{para}}^{(x_1\ldots x_n)}$ invariant (cf. eq. (2.60)).

Minimal takeaway for Chapter 2.

- Parasymmetry is formalized at three levels: (i) kinematic subspaces and projectors; (ii) a unified generator $U_G^{(\odot)}$ for its dynamics; and (iii) relational (Bell/W) implementations across PQSs (Definition 2.16, eqs. (2.56) and (2.59), and Section 2.2.3).
- Duality is upgraded to a global, fiberwise involution $\hat{D}^{(n)}_{\mathrm{PQS}}$ that coherently swaps Symmetry/Antisymmetry across the configuration (eq. (2.12)).
- Holosymmetry is implemented by controlled and interferometric gates $\mathbf{U}_{\mathrm{ctrl}}$, $\mathbf{U}_{\mathrm{Had}}$, $\mathbf{U}_{\mathrm{read}}$ that compare full dynamical histories via control-qubit interference (Definitions 2.114 and 2.123 and Sections 2.3.2 and 2.4.1).

Chapter 3: The Double-Slit Experiments

Chapter 3 reconceives the double-slit experiment as an interferometer on *histories*: the "slits" are whole, register-wide unitary evolutions on dual PQS arrays, steered by a control qubit through a Controlled Holosymmetric Operator $\mathbf{U}_{\mathrm{ctrl}}$ (Sections 2.3.2 and 3.1, Definition 2.114, and eq. (2.75)) [22, 47, 48, 20]. The symmetric protocol—Hadamard → controlled evolution → Hadamard—yields outcome probabilities

$$p_0 = \tfrac{1}{4}\left\|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right\|^2, \qquad p_1 = \tfrac{1}{4}\left\|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right\|^2,$$

(evaluated on the prepared register state; cf. Section 3.1.1 and Definition 2.123) [22, 26], so that visibility reduces to the real part of the overlap between the two path-evolved states, turning the control qubit into a calibrated meter of *functional symmetry* between dynamical branches (Section 3.1.2 and Theorem 3.4) [23, 24, 25]. What interferes here are not trajectories but full unitary evolutions; moreover, because each path operator itself encodes parasymmetric couplings, the architecture is recursive—interference of (structured) histories rather than of bare paths (Section 3.1 and eq. (2.56)) [49, 30, 29].

Asymmetric tomography and component expansions. Generalizing the beam-splitters to arbitrary $SU(2)$ rotations produces an *asymmetric* interferometer $\mathbf{U}^{(\mathrm{asym})}_{\mathrm{holo}} = \mathbf{U}_{\mathrm{read}}\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{prep}}$ that enables full tomography of the complex overlap $\mathcal{O}$ between histories: preparation (α, β) and readout (γ, δ) tune which quadrature of $\mathcal{O}$ is revealed in p_0, p_1 and hence in the visibility $\mathcal{V}_{\mathrm{asym}} = |p_0 - p_1|$ (Sections 3.1.5 and 3.1.7) [22, 26, 23, 24, 25]. At the operator level, both symmetric and asymmetric circuits admit recursive component expansions whose matrix elements (first- and second-order) act as channel-resolved amplitudes, exposing higher-order "interference of interference" and making the recursion experimentally legible (cf. Sections 3.1.5 and 3.1.8) [30, 29, 22]. In this extended setting, the overlap amplitude $\mathcal{M}$ generalises to $\mathcal{M}(U_{\mathrm{rel}}) = \mathrm{Tr}(\sqrt{\rho_a}\sqrt{\rho_b}\,U_{\mathrm{rel}})$, bounded above by the Uhlmann fidelity, which in turn constrains achievable visibility (Section 3.1.8) [50]. Triadic readouts supply square-sum envelopes over correlated/vacuum/spectral channels, sharpening design rules for selecting and interpreting holosymmetric fringes (Sections 3.1.8 and 12.2) [30].

Two interpretive lenses. First, the "interferometer of universal histories" reads the micro-experiment cosmologically: the particle $\mapsto$ dual-register state, the slits $\mapsto$ complementary evolutions, and the screen $\mapsto$ control-qubit statistics—suggesting that physical laws themselves may appear as stable interference patterns across competing histories (Section 3.1) [51, 20, 49]. Second, *commutator lensing* reframes interference as measured non-commutativity—e.g. $[\mathbf{U}_{\mathrm{Had}}, \mathbf{U}_{\mathrm{ctrl}}]$ in the symmetric case—thereby turning algebraic "twist" into an observable and promoting interference from a phenomenon within fixed laws to a probe of the algebra that organizes those laws (Section 3.3) [22, 30, 29].

Holosymmetric Interferometer and Visibility Bounds

Set-up and core quantity. The double-slit is recast as a holosymmetric interferometer (Section 3.1), with a control qubit toggling between two register-wide evolutions that interfere at readout. The central observable is the visibility

$$\mathcal{V} \;:=\; \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}} \in [0,1],$$

which, in the symmetric regime, equals the magnitude of an overlap amplitude $\mathcal{M}$ between two path histories ($\mathcal{V} = |\mathcal{M}|$; Section 3.1.2). Born-valued semantics align with Section 1.2.9.

Overlap amplitudes (pure and mixed histories). For pure histories, $\mathcal{M} = \langle\psi_a|\psi_b\rangle$. For mixed histories ρ_a, ρ_b,

$$\mathcal{M}(U_{\mathrm{rel}}) = \mathrm{Tr}\Big(\sqrt{\rho_a}\sqrt{\rho_b}\,U_{\mathrm{rel}}\Big), \qquad U_{\mathrm{rel}} \in \mathrm{U}(\mathrm{supp}\,\rho_a \cup \mathrm{supp}\,\rho_b),$$

with $U_{\mathrm{rel}} = \mathbb{I}$ in symmetric readout and U_{rel} adjustable by the control in the asymmetric case (Sections 3.1.1 and 3.1.5).

Symmetric interferometer. In the Mach–Zehnder–symmetric regime,

$$\boxed{\mathcal{V} \;=\; |\mathcal{M}| \;=\; |\langle\psi_a|\psi_b\rangle| \;\le\; 1} \qquad (\textit{Section 3.1.1}).$$

Asymmetric interferometer and universal inequality. For general $SU(2)$ preparation/readout on the control qubit, the visibility obeys

$$\boxed{\mathcal{V} \;\le\; |\langle\psi_a|\psi_b\rangle|},$$

with equality restored when the beam-splitter weights equalise path priors (Sections 3.1.5 and 3.1.7). Writing $U_c^{\mathrm{prep}} :\; |0\rangle \mapsto \alpha\,|0\rangle + \beta\,|1\rangle$ and $U_c^{\mathrm{read}} :\; \{|0\rangle, |1\rangle\} \mapsto \{\gamma\,|0\rangle + \delta\,|1\rangle,\; -\overline{\delta}\,|0\rangle + \overline{\gamma}\,|1\rangle\}$, with register-wide evolutions $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, the control probabilities are

$$p_0^{(\mathrm{asym})} = \Big\|\big(\gamma\alpha\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^*\beta\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\big)\,|\Psi_{\mathrm{RR}}\rangle\Big\|^2,$$
$$p_1^{(\mathrm{asym})} = \Big\|\big(\delta\alpha\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \gamma^*\beta\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\big)\,|\Psi_{\mathrm{RR}}\rangle\Big\|^2,$$

and the asymmetric-visibility definition

$$\mathcal{V}_{\mathrm{asym}} := \Big|p_0^{(\mathrm{asym})} - p_1^{(\mathrm{asym})}\Big|$$

matches Theorem 3.8.

Interferometric visibility bounds. Within the double-slit apparatus of Section 3.1 and with arbitrary control $U_c^{\text{prep}}, U_c^{\text{read}} \in SU(2)$ (thus encompassing symmetric and asymmetric regimes; cf. Sections 3.1.1 and 3.1.5), the following envelopes hold (Section 3.1.8):

1. *Universal "no-extra-control" bound.* If the total fringe is a sum of channel amplitudes $\mathcal{M} = \sum_\chi \mathcal{M}_\chi$, then

$$\boxed{\mathcal{V} \;\le\; \left|\sum_\chi \mathcal{M}_\chi\right| \;\le\; \sum_\chi |\mathcal{M}_\chi|}.$$

2. *Triadically weighted bound.* If readout applies complex weights w_χ with $\sum_\chi |w_\chi|^2 = 1$ (operationally by inserting $\sum_\chi w_\chi P_\chi$; cf. Section 12.2), then

$$\mathcal{M}(w) = \sum_\chi w_\chi \mathcal{M}_\chi, \qquad |\mathcal{M}(w)| \le \left(\sum_\chi |\mathcal{M}_\chi|^2\right)^{1/2},$$

with optimal envelope

$$\boxed{\mathcal{V}_{\max} \;\le\; \left(|\mathcal{M}_{\text{corr}}|^2 + |\mathcal{M}_{\text{vac}}|^2 + |\mathcal{M}_{\text{spec}}|^2\right)^{1/2}}.$$

Here each $\mathcal{M}_\chi$ is the expectation of the effect $E_\chi := P_\chi |\psi_b\rangle\langle\psi_a|$ in the experiment's GNS state (measurement protocol: insert P_χ and scan phase).

Mixed histories and fidelity ceiling. For mixed ρ_a, ρ_b, using the polar decomposition and the Uhlmann fidelity

$$F(\rho_a, \rho_b) = \left(\operatorname{Tr}\sqrt{\sqrt{\rho_a}\,\rho_b\,\sqrt{\rho_a}}\right)^2,$$

one obtains

$$\boxed{\mathcal{V} = |\mathcal{M}(U_{\text{rel}})| \;\le\; \sqrt{F(\rho_a, \rho_b)} \;\le\; 1},$$

with equality achieved by the polar-unitary choice $U_{\text{rel}} = V^\dagger$ of $\sqrt{\rho_a}\sqrt{\rho_b}$ (Section 3.1.8).

Readout design logic. The envelopes are operational: suitable choices of $U_c^{\text{prep}}, U_c^{\text{read}}$ (and, when needed, projectors P_χ) can (i) enforce robust lower bounds on $\mathcal{V}$; (ii) isolate correlated-signal contributions; and (iii) veto parasitic channels via the fidelity ceiling—rendering holosymmetric interference a diagnostic of global dynamics (Sections 3.1.8 and 12.2 and Theorem 3.8).

Minimal takeaway for Chapter 3.

- In the symmetric interferometer, $\mathcal{V} = |\langle\psi_a|\psi_b\rangle|$; under arbitrary $SU(2)$ control, $\mathcal{V} \le |\langle\psi_a|\psi_b\rangle|$ with equality recoverable by design (Sections 3.1.2, 3.1.5 and 3.1.7).
- For mixed histories, the Uhlmann fidelity governs the maximal visibility: $\mathcal{V} \le \sqrt{F(\rho_a, \rho_b)}$ (Section 3.1.8).

- Triadic readouts yield a square-sum envelope over correlated/vacuum/spectral channels, providing a principled best-case visibility strategy (Sections 3.1.8 and 12.2).

Foundations: Relations among Chapters 1, 2, and 3

From dialectic truth-values to interferometric visibilities. Chapter 1 establishes Born-valued semantics for the Fourfold facets—Thesis, Antithesis, Synthesis (Parasymmetry), and Holosymmetry—by assigning to each facet $\square \in \{\mathrm{T}, \mathrm{A}, \mathrm{S}, \mathrm{H}\}$ an effect $E_\square$ with valuation $v_\square(\rho) = \mathrm{Tr}(E_\square \rho)$ (Section 1.2.9 and Definition 1.18) [21, 22]. Chapter 3 realizes these same semantics operationally within a holosymmetric interferometer: the visibility $\mathcal{V}$ is expressed as the magnitude of an overlap amplitude $\mathcal{M}$, and, in the triadic readout, as expectations of channel-resolved effects $E_\chi = P_\chi \, |\psi_b\rangle\langle\psi_a|$ in the experiment's GNS state (Sections 3.1.1 and 3.1.8) [23, 24, 25, 26, 22, 30, 29]. Thus the "prism protocol" of Chapter 1, $\rho \mapsto (v_T, v_A, v_S, v_H)$, maps to Chapter 3's interferometric protocol $\rho \mapsto \mathcal{V}$ through explicit effect insertions and phase scans, with $\mathcal{V}$ bounded by $|\mathcal{M}|$ and further by triadic envelopes (Sections 3.1.8 and 12.2).

GNS actualization: from ontological labels to laboratory readouts. In Chapter 1, the Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ selects a representation $(\pi_{\overset{\circ}{\boldsymbol{\Psi}}}, \mathcal{H}_{\mathrm{em}}, |\Omega_{\omega^{\overset{\circ}{\boldsymbol{\Psi}}}}\rangle)$ via GNS, identifying valuations with ordinary expectations, $v(\rho; E) = \mathrm{Tr}\Big(\rho \, \pi_{\overset{\circ}{\boldsymbol{\Psi}}}(E)\Big)$ (Section 1.4.2 and Definition 1.18) [30, 29]. Chapter 3 uses this identification verbatim when writing $\mathcal{M}$ and $\mathcal{V}$ as expectation values of operators built from register-wide evolutions and selection projectors P_χ (Sections 3.1 and 3.1.8) [22, 30]. For mixed histories, the Uhlmann fidelity ceiling $\mathcal{V} \leq \sqrt{F(\rho_a, \rho_b)}$ is a representation-independent constraint on achievable expectations in the GNS arena (Section 3.1.8) [50].

Duality structure across scales. Chapter 1 formalizes a context-indexed involutive duality $\mathbf{D}_\mathcal{C}$ with status-compatibility and $\mathbf{D}_\mathcal{C}^2 = \mathrm{Id}$ (Definition 1.16). Chapter 2 realizes duality fiberwise at each PQS as $D^{(\mathfrak{B}_x)}$ and lifts it diagonally to $\hat{D}^{(n)}_{\mathrm{PQS}} = \bigotimes_i D^{(\mathfrak{B}_{x_i})}$ (Definition 2.7, Section 2.1.3, and eq. (2.12)). Chapter 3's symmetric interferometer effectively tests functional duality between complementary global evolutions $\hat{\mathbf{U}}^{A_G B_N}_{\mathrm{RR}}$ and $\hat{\mathbf{U}}^{A_N B_G}_{\mathrm{RR}}$: the outcome probabilities

$$p_0 = \tfrac{1}{4}\left\|\hat{\mathbf{U}}^{A_G B_N}_{\mathrm{RR}} + \hat{\mathbf{U}}^{A_N B_G}_{\mathrm{RR}}\right\|^2, \qquad p_1 = \tfrac{1}{4}\left\|\hat{\mathbf{U}}^{A_G B_N}_{\mathrm{RR}} - \hat{\mathbf{U}}^{A_N B_G}_{\mathrm{RR}}\right\|^2$$

encode constructive/destructive dual combinations under the Hadamard conjugation on the control (Section 3.1.1 and Definition 2.123). In this sense, the visibility equals $|\mathcal{M}|$ precisely when the dual branches are balanced by the $SU(2)$ beam splitters, reflecting the involutive exchange symmetry at the level of global histories (Sections 3.1.1 and 3.1.5).

Parasymmetry: from kinematics and generators to interfering histories. Chapter 2 identifies the parasymmetric axis locally by the projector $P^{(x)}_{\mathrm{para}}$ and relationally by Bell/W-like

projectors $P^{(xx')}_{\text{para}}$, $P^{(x_1\ldots x_n)}_{\text{para}}$ (Sections 2.2.1 and 2.2.3, Definition 2.17, and eqs. (2.58) and (2.59)) [22]. It further builds a unified generator

$$U_G^{(\odot)} = \exp\Big(i\,\hat{F}^{(\odot)}_{\text{para}}\Big)$$

aggregating local, pairwise, multipartite, and exchange dynamics (eq. (2.56)) [30, 29]. Chapter 3 treats the "slits" as entire parasymmetry-bearing histories: the global-evolution operators $\hat{\mathbf{U}}^{A_G B_N}_{\text{RR}}$ and $\hat{\mathbf{U}}^{A_N B_G}_{\text{RR}}$ are themselves composed of such generators, so the overlap amplitude $\mathcal{M}$ measures *coherence of coherence*—interference between structured parasymmetric evolutions rather than between featureless paths (Sections 3.1 and 3.1.8) [23, 24, 25, 49].

Holosymmetry: control-gate realization and effect semantics. Chapter 1 introduces holosymmetry as a facet whose operational effect interrogates *architecture* (Definition 1.18) [21, 22]. Chapter 2 supplies the gates: a controlled holosymmetric unitary

$$\mathbf{U}_{\text{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}^{A_G B_N}_{\text{RR}} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}^{A_N B_G}_{\text{RR}}$$

together with its Hadamard-conjugated form and a tunable readout gate $\mathbf{U}_{\text{read}}$ (Definition 2.114, eq. (2.75), and Sections 2.3.2 and 2.4.1) [22, 47, 48]. Chapter 3 composes these into symmetric and asymmetric interferometers, proving $\mathcal{V} = |\mathcal{M}|$ in the symmetric case and $\mathcal{V} \le |\langle\psi_a|\psi_b\rangle|$ in the asymmetric case, with equality recovered by suitable $SU(2)$ preparation/readout (Sections 3.1.2, 3.1.5 and 3.1.7) [26, 23, 24, 25, 22]. In triadic readouts, the insertion of P_χ implements a holosymmetric *selection principle* consistent with the effect-based semantics of Chapter 1 (Sections 3.1.8 and 12.2) [30, 29].

Inner products from the Holo-State vs. overlap amplitudes. Chapter 1 shows that the Holo-State fixes the local inner product on each modal fibre via Fourfold Inter-Modal Correlators (Proposition 1.30); this is the microscopic counterpart of Chapter 3's macroscopic overlap amplitude $\mathcal{M}$ between histories [23, 24, 25, 22]. The identification $\mathcal{V} = |\mathcal{M}|$ in the symmetric interferometer is therefore the direct laboratory manifestation of the state-defined inner-product geometry projected onto the "history" level (Section 3.1.1) [22, 26].

Algebra of Observables and channel decomposition. Chapter 1 constructs $\mathcal{A}(\mathcal{C}_d)$ as the operational language generated by geometric, matter, and symmetry fields (Definition 1.32) [30, 36, 37]. Chapter 3's channel amplitudes $\mathcal{M}_\chi$ and weights w_χ are implemented by inserting projectors/effects $P_\chi \in \mathcal{A}(\mathcal{C}_d)$ along each history, leading to universal and triadically weighted bounds,

$$\mathcal{V} \;\le\; \Big|\sum_\chi \mathcal{M}_\chi\Big| \;\le\; \sum_\chi |\mathcal{M}_\chi|, \qquad \mathcal{V}_{\max} \;\le\; \Big(|\mathcal{M}_{\text{corr}}|^2 + |\mathcal{M}_{\text{vac}}|^2 + |\mathcal{M}_{\text{spec}}|^2\Big)^{1/2},$$

which are algebraic consequences of $\mathcal{A}(\mathcal{C}_d)$-valued effect insertions and Cauchy–Schwarz in the GNS inner product (Section 3.1.8) [30, 29].

Commutator lensing as a probe of algebraic structure. The prism metaphor of Chapter 1 treats logic as structured interrogation; Chapter 3's *commutator lensing* realizes this as a probe of non-commutativity—e.g. $[\mathbf{U}_{\mathrm{Had}}, \mathbf{U}_{\mathrm{ctrl}}]$—thereby converting algebraic "twist" into measurable fringe shifts (Section 3.3) [22, 30, 29]. This aligns with Chapter 2's gate-level architecture and Chapter 1's thesis that algebraic structure precedes and organises phenomenology (Definitions 1.16 and 1.32).

Synthesis. The three chapters form a single pipeline:

$$\begin{aligned} &\text{Fourfold Dialectic (ontology) } (\textit{Definition } 1.16) \\ &\quad \Rightarrow\ \mathcal{A}(\mathcal{C}_d) \text{ (operational language) } (\textit{Definition } 1.32) \\ &\quad \Rightarrow\ |\overset{\circ}{\boldsymbol{\Psi}}\rangle \xrightarrow{\text{GNS}} (\mathcal{H}_{\mathrm{em}}, \pi_{\overset{\circ}{\boldsymbol{\Psi}}}) \ (\textit{Section } 1.4.2), \end{aligned}$$

with Chapter 2 supplying parasymmetric kinematics and holosymmetric gates (Section 2.2.1, eq. (2.56), and Definition 2.114) [22, 47, 48] and Chapter 3 turning these into interferometric visibility functionals and tomographic bounds (Sections 3.1.1, 3.1.5 and 3.1.8) [23, 24, 25, 22, 50]. The end result is a holosymmetric, testable semantics in which the logic of histories is read directly as calibrated visibilities.

Part II: The Continuum

Chapter 4: Modal Fibres and Emergent Hilbert Spaces

Chapter 4 develops the kinematic heart of the programme: a gauge-covariant, operator-valued *Fourfold Inter-Modal Correlator* that couples Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry across loci of Primordial Quantum Singularities and thereby generates the local modal geometry (Definitions 1.16 and 4.9) [30, 36, 37, 25, 24, 23]. Formally, the correlator $\hat{\mathbf{G}}_\Lambda(x,x') = [\hat{G}_\Lambda^{\alpha\beta}(x,x')]_{\alpha,\beta\in\{0,1,p,s\}}$ is defined by imprint–transport–readout channels built from field modes and a parallel transporter $\mathcal{U}$ (Definition 4.9 and Section 4.1.4) [23, 24, 25, 45]; its diagonal entries track modal persistence, while off-diagonals register interference and cross-mode conversion, with the Twofold $\{0,1\}$ block recovering the dyad and the remaining blocks encoding parasymmetric/holosymmetric couplings (Sections 1.2.8 and 4.1.5) [22, 26]. This kernel is not merely descriptive: the inner product on each modal fibre $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ is *forged* from its Holo-State expectation in the coincident limit, so the Hilbert geometry is emergent and state-dependent (Sections 1.4.2 and 4.6) [30, 29, 36]. Parallel transport along $\gamma \subset \mathcal{X}_q$ ensures frame-consistent comparison of modes between loci (Section 4.1.4) [23, 24, 25, 45]. In commuting/decohered regimes the off-blocks carry no independent signal and the Fourfold collapses to the Twofold classical slice, restoring Non-Contradiction and Excluded Middle on their proper domain (Section 1.2.8) [22, 27, 28].

Bundle, grading, and qubit-recovery regimes. Algebraically, the correlator carries a $\mathbb{Z}_2 \times \mathbb{Z}_2$ "color'' grading that preserves degrees under composition and dictates commutator/anti-commutator selection rules among channels, ensuring that dyadic, parasymmetric, and

holosymmetric couplings compose without violating the prismatic architecture (Section 4.1.7) [52, 30]. These fibres assemble into a rank-4 Hermitian bundle over the emergent configuration space $\mathcal{X}_q$, with ordered orthonormal frames $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ chosen only *after* the correlator-defined metric is fixed; the Twofold and (p, s) sectors are each 2-dimensional, and the full kernel appears as a 4×4 matrix in modal indices (and, in the geometry–matter refinement, as a matrix of such matrices) (Section 4.6.1 and Definition 1.32) [45, 36, 37, 30]. A *duality-collapse* regime is singled out: when cross-block expectations $\{0, 1\} \leftrightarrow \{p, s\}$ are suppressed and the Twofold block is non-degenerate, standard qubit kinematics is recovered up to isometry, with Born statistics reproduced on an effective $\mathbb{C}^2$ (Section 4.1.6) [22].

Holosymmetry, sections, and co-construction with the state. Conceptually, Holosymmetry supplies a system-level invariant that calibrates the entire Fourfold without being scrambled by local mixings (Section 3.8), while the modal weights carried by global sections (dialectic quantum fields) propagate covariantly along connections on the bundle (Sections 4.1.4 and 4.6.1) [45, 23, 24, 25]. Thus, modal fibres and their inner products are co-constructed with the universal state via GNS (Section 1.4.2) [30, 29]; qubits arise as special Twofold regimes (Section 4.1.6) [22]; and the correlator functions as the relational kernel that both *measures* and *makes* the Hilbert geometry on which the Fourfold logic is read (Definition 4.9 and Section 4.6) [36, 37].

Correlator-Induced Modal Geometry and Holonomy

GNS layer and represented operators. From the Quantum Holo-State $\omega^{\mathring{\mathbf{\Psi}}}$ on the C^*-algebra $\mathcal{A}(\mathcal{C}_d)$, the GNS construction yields the cyclic triple

$$(\pi_{\mathring{\mathbf{\Psi}}},\ \mathcal{H}_{\mathring{\mathbf{\Psi}}},\ |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle), \qquad \mathcal{H}_{\mathrm{em}} \equiv \mathcal{H}_{\mathring{\mathbf{\Psi}}},$$

identifying Born-valued valuations with ordinary expectations $v(\rho; E) = \mathrm{Tr}\Big(\rho\, \pi_{\mathring{\mathbf{\Psi}}}(E)\Big)$ (Section 1.4.2 and Definition 1.18). Hatted symbols denote represented operators on $\mathcal{H}_{\mathrm{em}}$.

Fourfold Inter-Modal Correlator and fibre metric. For each PQS $\mathfrak{B}_x$, the inner product on the modal fibre $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ is *generated* by the Fourfold Inter-Modal Correlator via the coincident-limit expectation

$$\langle \psi_1 | \psi_2 \rangle_x := \lim_{x' \to x} \left\langle \mathring{\mathbf{\Psi}} \middle| \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \middle| \mathring{\mathbf{\Psi}} \right\rangle,$$

which, upon positivity and completion, metrises the fibre (Section 4.1.3; cf. Proposition 1.30). Thus $\mathcal{H}_{\mathrm{em}}$ provides the representation, while Holo-State expectations *forge* the modal metrics.

Tensor form and channel structure. Fix $\mathcal{I} = \{0, 1, p, s\}$ and choose a realisation $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ after the metric is defined. The correlator is the 4×4 operator-valued kernel $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}_\Lambda^{\alpha\beta}(x, x')]_{\alpha,\beta \in \mathcal{I}}$ with entries

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') := \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x') \in \mathcal{B}(\mathcal{H}_{\mathrm{em}}),$$

where $\mathcal{U}$ is the gauge-covariant transporter along γ (Section 4.1.5). The top-left Twofold block $\hat{\mathbf{G}}_{(0,1)}$ obeys Hermitian symmetry and gauge covariance; parasymmetric/holosymmetric effects require the full Fourfold kernel (cf. Section 4.1.3).

Parallel transport, curvature, and holonomy. A metric-compatible connection on the modal bundle provides

$$\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{P}\, \exp\Big(-\int_\gamma \mathcal{A}\Big),$$
$$\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A} \wedge \mathcal{A}.$$

so that flat regions ($\mathcal{F} = 0$) are path-independent, while nonzero curvature yields holonomy. Loop holonomy $\mathrm{Hol}_\ell = \mathcal{P} \exp(-\oint_\ell \mathcal{A})$ defines holosymmetric observables through loop operators (insertion in the s-channel), whose Holo-State expectations operationalise global fibre-bundle geometry (Section 4.1.3).

Hilbert bundle over $\mathcal{X}_q$ and dimensional summary. The fibres $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ assemble into a Hilbert bundle

$$(\mathscr{H}_{\mathrm{mod}}, \pi, \mathcal{X}_q), \qquad \mathscr{H}_{\mathrm{mod}} := \bigsqcup_{x \in \mathcal{X}_q} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}, \quad \pi^{-1}(x) \cong \mathbb{C}^4,$$

cleanly separating representation space $\mathcal{H}_{\mathrm{em}}$ from modal fibres. Typical sizes: $\dim_{\mathbb{C}} \mathcal{H}_{\mathrm{em}} = \infty$ (usually separable), $\dim_{\mathbb{C}} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = 4$, and $\dim_{\mathbb{C}} \mathcal{H}_{\alpha,x} = 1$ for $\alpha \in \{0, 1, p, s\}$ (cf. Section 4.1.3).

Twofold vs. Fourfold: not permutation symmetry. The dialectic (anti)symmetries are *internal* PQS structures, distinct from the many-body permutation symmetries; likewise $|p\rangle_x$ and $|s\rangle_x$ are independent basis rays (not $|\pm\rangle_x$ superpositions), while the parasymmetric $|+\rangle_x$ defines an *effect* $P_{\mathrm{para}}^{(x)}$ in the Twofold sector (Section 4.1.5).

Qubit relocation, registers, and holomodal computing. When the Twofold sector is dynamically protected and the correlator is block-diagonalisable, a Qubit Reduction $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ realises effective qubits, and suppressing inter-fibre cross-correlators yields n-site registers $(\mathbb{C}^2)^{\otimes n}$. This both contains the standard qubit model and extends it by native Fourfold controls and effects (cf. Section 4.1.3). The resulting *holomodal* architecture aligns parasymmetric/holosymmetric channels with the POVM toolbox defined on $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32).

Alignment with Chapters 1 and 2. The Fourfold roles (Thesis/Antithesis/Parasymmetry/Holosymmetry) acquire metric meaning through $\hat{\mathbf{G}}_\Lambda$, realising the "prism for discourse" within the emergent arena (Section 1.2.8). Local involutive duality $D^{(\mathfrak{B}_x)}$ and its global lift $\hat{D}_{\mathrm{PQS}}^{(n)}$ act naturally on the metrised fibres and their registers (Definition 2.7, Section 2.1.3, and eq. (2.12)), while the Twofold sector $\mathcal{H}_{(0,1)}$ embeds canonically inside $\mathbb{C}^4$ (Section 2.2). In this way, Chapter 4 completes the ontology ⇒ algebra ⇒ GNS pipeline (Definitions 1.16 and 1.32 and Section 1.4.2) by deriving a *state-dependent, correlator-forged* modal geometry whose curvature and holonomy become holosymmetric observables.

Chapter 4 systematises the operator-geometric architecture of the $\hat{\Omega}$-Continuum by introducing a fibre bundle of relational readouts $\pi : \mathfrak{F} \to \mathcal{X}_q$ whose fibres split as $\mathcal{F}_x^{\mathrm{dist}} \times \mathcal{F}_x^{\mathrm{time}}$,

packaging a distance triad $\vec{d} = (d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}})$ and a time (phase-displacement) triad $\vec{t} = (t_{\text{corr}}, t_{\text{vac}}, t_{\text{spec}})$; the construction is smooth and gauge/frame-covariant, with $D(x, x') = \|\vec{d}(x, x')\|_2$ playing a metric-like role while $\vec{t}$ tracks relational phase flow (Definitions 4.599, 4.600 and 4.604) [45, 36, 37, 30]. The triad's axes are defined and compared in a gauge-covariant manner via the Fourfold correlator and its parallel transport, rendering "universal entanglement" an intrinsic, background-free bilocal amplitude that is one leg of the emergent relational geometry/time triad (Sections 4.1.2 and 4.12) [23, 24, 25, 22].

A central technical role is assigned to the Spectral Operator $\hat{D}$ (the differential generator), whose commutator with the Fourfold channels yields the spectral distance/time pair; the spectral-shear time t_{spec} is defined as an ℓ^2 aggregate of imaginary parts of spectral-shear profiles, is a pseudometric, and obeys the duality bound $t_{\text{spec}} \leq d_{\text{spec}}$ with equality for purely imaginary shears (Definition 4.341 and Section 4.12.5) [36, 37, 29]. A rate 1-form furnishes a path-integral "accumulated spectral time," making temporal holonomy and curvature explicit; if $t_{\text{spec}} \equiv 0$ globally, the spectral connection is flat, the spectral distance collapses, and $[\hat{D}, \hat{G}_\Lambda(\cdot)]$ vanishes (in expectation and, under mild hypotheses, as an operator) on the GNS cyclic subspace—i.e., the spectral sector is strongly static (Sections 4.12.5 and 4.12.9) [45, 30]. The vacuum-response time is developed in parallel (with a rate 1-form), interpreting t_{vac} as a background-free analogue of retarded vacuum reaction familiar from QFT in curved backgrounds (Section 4.12.3), conceptually resonant with [53, 51].

Structurally, the chapter distinguishes the kinematic inner product on each modal fibre (complex Hermitian; interference) from a geometric inner product on $\mathcal{F}_x$ (real Euclidean; aggregation of distances), and proves well-posedness and functional independence of the triadic generators (via a Fréchet argument), together with endogenous finiteness: under Spectral Smoothness and Finite Entanglement Capacity, all six observables $d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}}, t_{\text{corr}}, t_{\text{vac}}, t_{\text{spec}}$ are finite with a state-dependent effective spectral cutoff (Sections 4.9.11 and 4.11.5 and Proposition 4.605) [30, 29, 36].

Finally, the "Fibred Continuum of Primordial Quantum Singularities" is defined: PQS loci are relational-null classes $(\vec{d}, \vec{t}) = \mathbf{0}$ that carry the universal duality code $\overset{\circ}{\Lambda}_{\hat{\Theta}}^{\hat{\Phi}}$; the correlator both induces the local fibre metric (coincident limit) and mediates gauge-covariant comparisons across the continuum, so that ontological (operator-level) entanglement reduces to familiar phenomenological entanglement precisely when the Twofold block decouples (Sections 4.6 and 4.18) [22, 23, 24].

Chapter 4 develops an *intrinsic*, operator-theoretic geometry and chronology on the emergent configuration space $\mathcal{X}_q$. The central ingredients are the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda$ (cf. Definition 4.9), the gauge-covariant transporter $\mathcal{U}(x \leftarrow x'; \gamma)$, and an admissible Spectral Operator $\hat{D}$ (cf. Definition 4.343). Together they define three *axes* of distinguishability—$(d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}})$—and their temporal complements—$(t_{\text{corr}}, t_{\text{vac}}, t_{\text{spec}})$—which are assembled fibrewise into a relational bundle over $\mathcal{X}_q$ and then into composite, macroscopic notions of distance and time (cf. Sections 4.10.2, 4.11.3, 4.12 and 5.3.8). At the kinematic level this rests on gauge-covariant comparison of modal data across loci via $\mathcal{U}$, ensuring observer-independent channel operators $\hat{G}_\Lambda^{\alpha\beta}(x, x')$.

Chronogeometric fibres and the expectation-level split

For each relational point $x \in \mathcal{X}_q$, the emergent chronogeometric data are organised into the set-level product fibre

$$\boxed{\mathfrak{F}_x := \mathcal{F}_x^{\mathrm{dist}} \times \mathcal{F}_x^{\mathrm{time}}} \tag{1}$$

(cf. Definitions 4.599 and 4.600), with modal coordinates expressed in the Fourfold dialectic basis $\{\, \mathring{\mathbf{0}},\ \mathring{\mathbf{1}},\ \mathring{\mathbf{0}}{+}\mathring{\mathbf{1}},\ \mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{1}}}^{\mathring{\mathbf{0}}} \,\}$ (Fourfold; cf. Definition 4.9).

At the expectation level the chronogeometric tensor splits into orthogonal summands

$$\boxed{\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}} \tag{2}$$

where $\bar{g}_{\mu\nu}$ is sourced by distinguishability data and $\bar{t}_{\mu\nu}$ by temporal-phase data (cf. Definitions 4.599 and 4.600).

The Relational Distinguishability Fibre

As defined earlier (see Definition 4.599), for each $x \in \mathcal{X}_q$ the *Relational Distinguishability Fibre* collects the three, functionally orthogonal axes of distinguishability into a single fibre over x:

$$\mathcal{F}_x^{\mathrm{dist}} \;=\; \Big\{\, \vec{d}(x,x') \;:=\; \big(d_{\mathrm{corr}}(x,x'),\, d_{\mathrm{vac}}(x,x'),\, d_{\mathrm{spec}}(x,x')\big) \in \mathbb{R}^3 \;:\; x' \in \mathcal{X}_q \,\Big\},$$

and the composite (Euclidean) distinguishability is

$$D(x,x') \;:=\; \|\vec{d}(x,x')\|_2.$$

Narratively, d_{corr} probes bilocal coherence via the off-diagonal sector of the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda$ (cf. Definition 4.9); d_{vac} captures the coincident/diagonal contrast—the "vacuum-response" leg—within the same correlator; and d_{spec} measures commutator-induced spectral shear generated by the admissible spectral operator $\hat{D}$ (cf. Definition 4.343). These axes assemble the set-level fibre used throughout the triadic metric construction (cf. Sections 4.10.2 and 4.11.3) and underpin the orthogonality and independence results established later (cf. Sections 4.10.1 and 4.11.5).

The Temporal Flow Fibre

As defined earlier (see Definition 4.600), for each $x \in \mathcal{X}_q$ the *Temporal Flow Fibre* gathers the phase-like temporal complements of the triad into a single fibre over x:

$$\mathcal{F}_x^{\mathrm{time}} \;:=\; \Big\{\, \vec{t}(x,x') \;:=\; \big(t_{\mathrm{corr}}(x,x'),\, t_{\mathrm{vac}}(x,x'),\, t_{\mathrm{spec}}(x,x')\big) \in \mathbb{R}^3 \;:\; x' \in \mathcal{X}_q \,\Big\}.$$

These are *phase-type* temporal quantities (not metrics) that arise from operator-theoretic evolution along admissible transports, and they supply the temporal summand $\bar{t}_{\mu\nu}$ in the orthogonal split $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (cf. eq. (2)), in complement to the distinguishability fibre $\mathcal{F}_x^{\mathrm{dist}}$ (cf. Definition 4.599).

Narratively:

- t_{corr} is the *entanglement phase time* extracted from the argument of the correlator expectation along an admissible path, with unwrapped lift, basic antisymmetry/additivity properties, and a differential phase-rate 1-form (cf. Definitions 4.523 and 4.527, eq. (4.243), Proposition 4.526, and Remark 4.528).
- t_{vac} quantifies the *vacuum-response* (diagonal/coincident sector) via a gauge-covariant rate 1-form whose path integral bounds the net temporal response (cf. Definition 4.537 and Section 4.12.3).
- t_{spec} is the temporal parameter associated with *spectral shear* generated by the admissible spectral operator $\hat{D}$, paired with the self-regularising spectral distance and its observables (cf. Section 4.12.5 and Definitions 4.386 and 4.428).

Together, $\vec{t}$ provides the temporal counterpart to the distinguishability triad, ensuring a coherent, gauge-covariant time structure across $\mathcal{X}_q$ that is functionally aligned with the distance axes used in the composite metric construction (cf. Sections 4.11.3 and 4.12).

The triadic axes of relational distance and time

The continuum's geometry is organised by the *triad*

$$\vec{d}(x,x') = \big(d_{\mathrm{corr}},\, d_{\mathrm{vac}},\, d_{\mathrm{spec}}\big), \qquad \vec{t}(x,x') = \big(t_{\mathrm{corr}},\, t_{\mathrm{vac}},\, t_{\mathrm{spec}}\big),$$

where d_{corr} probes bilocal coherence (off-diagonal sector of $\hat{G}_\Lambda$), d_{vac} probes coincident/diagonal contrasts (vacuum response), and d_{spec} probes commutator-induced spectral shear via $[\hat{D}, \hat{G}_\Lambda]$. The three axes are *functionally orthogonal* and assembled in the Relational Distinguishability Fibre (cf. Section 4.11.3); their specialisation to *emergent proper* quantities is deferred to Section 5.3.8.

Entanglement phase time

As defined earlier (see Definition 4.523), the entanglement phase time along an admissible path γ with nonvanishing correlator expectation $\Gamma_{\mathrm{corr}}(x,x';\gamma)$ is

$$t_{\mathrm{corr}}(x,x';\gamma) := \operatorname{Arg}\, \Gamma_{\mathrm{corr}}(x,x';\gamma) \in (-\pi,\pi], \qquad t_{\mathrm{corr}}(x,x;\cdot) = 0 \quad \text{(cf. eq. (4.243))}.$$

The *unwrapped* phase $\tilde{t}_{\mathrm{corr}} \in \mathbb{R}$ is obtained by continuous lift along node-avoiding homotopies and is unique up to $2\pi\mathbb{Z}$. For later use, we also record the differential phase-rate 1-form (cf. Definition 4.527)

$$\dot{t}_{\mathrm{corr}}(s) = \operatorname{Im}\!\left(\frac{\dot{\Gamma}_{\mathrm{corr}}(s)}{\Gamma_{\mathrm{corr}}(s)}\right), \qquad t_{\mathrm{corr}} = \int \dot{t}_{\mathrm{corr}}\, ds.$$

It enjoys antisymmetry, additivity under concatenation, and loop holonomy (cf. Proposition 4.526). Its transport dependence is captured by the differential phase-rate 1-form

$$\dot{t}_{\mathrm{corr}}(s) = \operatorname{Im}\!\left(\frac{\dot{\Gamma}_{\mathrm{corr}}(s)}{\Gamma_{\mathrm{corr}}(s)}\right), \qquad t_{\mathrm{corr}} = \int \dot{t}_{\mathrm{corr}}\, ds \quad \text{(cf. Definition 4.527)}.$$

Writing $\Gamma_{\mathrm{corr}} = |\Gamma_{\mathrm{corr}}|e^{it_{\mathrm{corr}}}$ exhibits magnitude/phase complementarity: d_{corr} and t_{corr} are respectively the modulus and argument of the same gauge-covariant expectation (cf. Remark 4.528). At nodes where $\Gamma_{\mathrm{corr}} = 0$, employ the reference-admixture regularisation (cf. Remark 4.524 and Definition 4.523).

Vacuum-response time

The vacuum-response time t_{vac} quantifies the retarded internal reaction of the "vacuum" sector (diagonal/coincident data of $\hat{G}_\Lambda$) to modal shifts. Along a C^1 path γ define the gauge-covariant *rate 1-form*

$$\dot{t}_{\mathrm{vac}}(s) := \left[\sum_k \left(\tfrac{d}{ds}\ \mathrm{Im}\, C_k(\gamma(s))\right)^2\right]^{1/2}, \qquad T_{\mathrm{vac}}(x,x';\gamma) := \int_0^1 \dot{t}_{\mathrm{vac}}(s)\, ds,$$

with $t_{\mathrm{vac}}(x,x') \le T_{\mathrm{vac}}(x,x';\gamma)$ and equality for straight-line profiles in ℓ^2 (cf. Definition 4.537 and Section 4.12.3). Physically, t_{vac} extracts the phase-encoded polarisation/gauge-flow response in the coincident sector, rendered intrinsic and background-free via the Holo-State and $\hat{G}_\Lambda$ (cf. Section 4.12.3).

Spectral shear time and distance

The spectral axis is governed by the commutator "shear" with $\hat{D}$. A key result is the *Self-Regularizing Spectral Distance*:

$$d_{\mathrm{spec}}(x,x') := \left(\sum_n w_n^2(x,x')\left|\mathcal{S}_n(x,x')\right|^2\right)^{1/2},$$
$$\mathcal{S}_n(x,x') := \left\langle \overset{\circ}{\boldsymbol{\Psi}}\right| [\hat{D}, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_n^*, \psi_n]] \left|\overset{\circ}{\boldsymbol{\Psi}}\right\rangle,$$

where w_n are *modal weights* implementing state-conditioned ultraviolet control (cf. Definitions 4.386, 4.392 and 4.428, Axiom 4.415, and Principle 4.1). No external cutoff is needed; finiteness is a property of the operator algebra plus the Holo-State, and d_{spec} is monotone under coarse-graining (Remark after Definition 4.428). The associated temporal parameter t_{spec} is introduced in Section 4.12.5.

Functional orthogonality and Fréchet independence. At the *operator* level, the triad is generated by

$$\mathbf{A}_{\mathrm{corr}}(x,x') := \hat{G}_\Lambda(x,x') \quad \text{(off-diagonal coherence)},$$
$$\mathbf{A}_{\mathrm{vac}}(x,x') := \hat{G}_\Lambda(x,x) - \hat{G}_\Lambda(x',x') \quad \text{(diagonal contrast)},$$
$$\mathbf{A}_{\mathrm{spec}}(x,x') := i[\hat{D}, \hat{G}_\Lambda(x,x')] \quad \text{(spectral shear)}.$$

Functional *orthogonality* under the emergent fibre inner product is established in Sections 4.10.1 and 4.10.2, while a Fréchet-differential argument proves *functional independence* (cf. Section 4.11.5).

Kinematic vs geometric inner products. Chapter 4 distinguishes the *modal* inner product on $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ (Hermitian; fixes local amplitudes/interference) from the *fibre* inner product on $\mathcal{F}_x$ (Euclidean; aggregates distance triples into the composite $D(x, x')$), aligning first-order quantum kinematics with second-order emergent geometry (cf. table 4.3).

State-conditioned modal weight & endogenous regularization. As formalised in Section 4.9.7, the spectral leg weights each modal contribution by a *state-conditioned* factor $w_n(x, x')$ built from the $\hat{D}$-commutator "shear" of the bilocal channel $\hat{G}_\Lambda$ and evaluated in the Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ [36, 37, 30, 29]. A convenient (Hilbert–Schmidt) realisation used in the chapter is

$$w_n^2(x, x') \;:=\; 1 + \Big\| \Big[\hat{D},\ \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_n^*, \psi_n]\Big] \Big\|^2_{\text{HS},\,\mathring{\mathbf{\Psi}}},$$

so the weights are fixed endogenously by the operator algebra and the Holo-State [30, 29, 36]. The underlying shear observable employed throughout is

$$\mathcal{S}_n(x, x') \;:=\; \Big\langle \mathring{\mathbf{\Psi}} \Big| \Big[\hat{D},\ \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_n^*, \psi_n]\Big] \Big| \mathring{\mathbf{\Psi}} \Big\rangle,$$

see Section 4.9.3 and Definition 4.341 [36, 37]. This construction is tied to the PQS coherence/IR scale and to the "effective spectral cutoff" emerging from Spectral/Relational Smoothness and Finite Entanglement Capacity, i.e. from the same endogenous mechanism rather than any external regulator (cf. the discussion surrounding Section 4.9.7) [37, 29].

Endogenous finiteness of spectral distance. With w_n fixed as above and $\mathcal{S}_n$ the spectral shear, Chapter 5 proves that the weighted spectral sum defining the spectral-axis distance is finite *without* external regularisers; the convergence and its stability under coarse-graining follow solely from the state-conditioned smoothness/growth encoded in w_n [36, 37, 30, 29]. This is the "endogenous finiteness of spectral distance" in Section 4.9.11.

Principle of Coherent Regularization. The chapter imposes a sharp rule (see Section 4.9.13): incoherent, externally imposed cutoffs are disallowed. Admissible regularisation must be implemented *coherently* via the modal weights determined by $|\mathring{\mathbf{\Psi}}\rangle$ [30, 29]. In particular, the weights obey a superpolynomial decay in the spectral index/eigenvalue (the Spectral/Relational Smoothness condition), which suffices for the endogenous finiteness above and renders the construction scheme-independent [36, 37].

The self-regularizing geometry. Combining coherent, state-conditioned weighting with endogenous finiteness yields a *self-regularizing* UV picture: the triadic geometry—and in particular the spectral leg—is finite and well-defined purely from $\hat{G}_\Lambda$, $\hat{D}$, and $|\mathring{\mathbf{\Psi}}\rangle$ [36, 37, 30, 29]. This is summarised in Section 4.9.14, and explicitly linked back to Sections 4.9.7, 4.9.11 and 4.9.13.

A relational framework for infrared (IR) regularization. Beyond the UV, Chapter 4 develops a *relational* IR scheme (cf. Section 4.9.15): long-distance behaviour is windowed by relational constructs along paths γ using the gauge-covariant transporter $\mathcal{U}(x \leftarrow x'; \gamma)$, not by background momenta [45, 23, 24, 25]. An IR coherence scale (defined in that section) limits the accumulation of shear/coherence along γ and controls correlator tails [53, 51].

Reciprocal Resolution Limits. Within this framework, Section 4.9.15 establishes reciprocal bounds linking spectral-axis distinguishability and effective spatial/temporal resolution: small spectral distinguishability enforces a lower bound on macroscopic resolving power, and conversely, coarse resolution bounds spectral sensitivity [54]. A "band-limited data" corollary captures the practical coarse-measurement regime [55].

State-dependent spectral gapping. Finally, Section 4.9.15 proves the existence (on compact $\mathcal{X}_q$, for a dense set of Holo-States) of a positive, *state-dependent* commutator gap $\Delta\big(|\mathring{\mathbf{\Psi}}\rangle\big) > 0$ for the $\hat{D}$–$\hat{G}_\Lambda$ dynamics. The gap is intrinsic (state-conditioned algebraic property), stable under small deformations of $|\mathring{\mathbf{\Psi}}\rangle$ and of the local algebra, and enjoys topological protection in the presence of nontrivial bundles—feeding back into the relational IR picture by enforcing coherence windows at large separations [36, 30, 29, 45].

Placement in the triad. All of the above sits inside the triadic kinematics

$$\vec{d} = (d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}}), \qquad \vec{t} = (t_{\text{corr}}, t_{\text{vac}}, t_{\text{spec}}),$$

with the spectral leg driven by $\hat{D}$–shear and assembled, alongside the correlational and vacuum legs, into the Relational Distinguishability Fibre (cf. Section 4.11.3) and its temporal counterpart (cf. Section 4.12).

Emergence and regularity of the configuration space $\mathcal{X}_q$. The relational quotient $\pi_q : \mathcal{C}_d \to \mathcal{X}_q := \mathcal{C}_d/\sim$ (see eq. (4.322)) furnishes $\mathcal{X}_q$ with a unique smooth structure [45, 30, 29, 36, 37]. A regular foliation by leaves $\{\mathfrak{B}_x\}$ of locally constant dimension yields transversal slices $S_x \subset \mathcal{C}_d$ for which $\pi_q|_{S_x}$ are charts with full-rank differentials; thus π_q is a smooth submersion [45, 43, 44]. Assuming $\dim \mathfrak{B}_x = m$ locally constant, $\dim \mathcal{X}_q = d - m$ [45]. Because the relation set R is a closed embedded submanifold and the leaves are uniformly localised (cf. eq. (4.303)), distinct equivalence classes admit disjoint saturated neighbourhoods, so $\mathcal{X}_q$ is Hausdorff; second-countability descends from $\mathcal{C}_d$ via openness of π_q and a countable slice basis [45, 29]. Cardinality is preserved: if $|\mathcal{C}_d| = \mathfrak{c}$, then $|\mathcal{X}_q| = \mathfrak{c}$ (cf. Section 4.19.4).

PQS locus, null condition, and factorization. A PQS locus is characterised by the *relational null condition* $\vec{d} = \vec{t} = \mathbf{0}$ (together with vanishing of complementary components), pinpointing the "zero" of the emergent metric–temporal structure (cf. Section 4.9) [36, 37]. Global non-factorizability of the Holo-State underwrites connected chronogeometry and nontrivial holosymmetric interference; exact factorization would force a block structure that trivialises cross-sector functionals and the axis-specific temporal parameters [30, 29]. A precise "FAPP" statement shows how subsystems can behave autonomously when trace-distance corrections lie

below experimental resolution, without violating global non-factorizability (cf. Theorem 4.314, Proposition 4.312, and Sections 4.12 and 5.3.8) [22, 45, 43, 44].

Ontological vs phenomenological entanglement and qubit reduction. The chapter separates *ontological* entanglement (default correlator-level coherence in the $\hat{\Omega}$–Continuum) from *phenomenological* entanglement in fixed tensor-product arenas. When the Fourfold's Twofold block decouples and cross-correlators are suppressed, one recovers $(\mathbb{C}^2)^{\otimes n}$ registers and standard entangling gates; in this regime the IQR machinery reduces to familiar quantum-information dynamics (cf. Proposition 4.300 and Corollary 4.302).

Conceptual synthesis & minimal takeaway for Chapter 4.

1. **Intrinsic tri-axial atlas.** The triads $\vec{d}$ and $\vec{t}$ define an *intrinsic atlas* of distinguishability and temporal flow on $\mathcal{X}_q$, anchored in gauge-covariant, state-dependent expectations of $\hat{G}_\Lambda$ and $[\hat{D}, \hat{G}_\Lambda]$. The emergent representation $\mathcal{H}_{\text{em}}$ is provided by GNS, and the modal fibre metrics are *derived* from Fourfold correlator expectations (Sections 1.4.2 and 4.1.3).

2. **Self-regularising spectral leg.** The spectral leg is *self-regularising*: finiteness and scheme-independence arise from modal weights and Holo-State conditioning rather than external cutoffs (cf. Definition 4.428 and Remark thereafter).

3. **Geometry, holonomy, and operational closure.** Gauge-covariant transport and curvature of the correlator produce holonomy; loop operators render this geometry operational in the holosymmetric channel, knitting local rules to global structure through the composite tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (Section 4.1.3).

4. **Factorisation and protected sectors.** Exact factorisation is obstructive; approximate (FAPP) factorisation explains emergent autonomy without abandoning the global, correlator-driven geometry and time. Twofold qubit sectors arise as protected, block-diagonalisable limits of the Fourfold structure; registers $(\mathbb{C}^2)^{\otimes n}$ are special cases within a holomodal, correlator-driven architecture (Section 4.1.5 and Definition 1.32).

Altogether, Chapter 4 shows how the Fourfold logic (Definition 4.9), together with the GNS/emergent construction (Section 1.4.2) and the admissible spectral operator $\hat{D}$, yields a concrete, tri-axial metric–temporal calculus on $\mathcal{X}_q$ [30, 29, 36, 37]. *Distances* arise from correlator magnitude, vacuum contrast, and spectral shear; *times* from entanglement phase, vacuum response, and spectral-shear rates—each axis gauge-covariant, functionally orthogonal, and tied to specific operator features of $\hat{G}_\Lambda$ and $[\hat{D}, \hat{G}_\Lambda]$ [23, 24, 25, 22]. The spectral leg is *self-regularising* (no external cutoffs), with finiteness controlled by modal weights and Holo-State conditioning (cf. Definition 4.428) [36, 37, 30, 29]; gauge-covariant transport and curvature of the correlator produce holonomy and close operationally via loop operators in the holosymmetric channel (Section 4.1.3) [45, 23, 24, 25]. The kinematic modal product and the geometric fibre product cohere local interference rules with global metric structure through the composite tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (Section 4.1.3) [30, 29, 45].

In this calculus, exact factorisation is generically obstructed; nevertheless, approximate (FAPP) factorisation accounts for emergent autonomy without relinquishing the correlator-driven global geometry and time [30, 29, 22]. Twofold qubit sectors appear as protected, block-diagonalisable limits of the Fourfold architecture, with registers $(\mathbb{C}^2)^{\otimes n}$ as special cases within the holomodal framework (Section 4.1.5 and Definition 1.32) [22]. The relational bundle $\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \times \mathcal{F}_x^{\text{time}}$ with Fourfold-dialectic coordinates provides the canonical staging for these constructions and for their specialisation to emergent proper quantities (Section 5.3.8) [45, 36, 37].

In plain terms, Chapter 4 builds the **ruler** and the **clock** out of correlations themselves. Starting from the Fourfold inter-modal correlator $\hat{G}_\Lambda$ (Definition 4.9) and an admissible spectral operator $\hat{D}$, it uses the GNS construction to obtain an emergent representation $\mathcal{H}_{\text{em}}$ (Section 1.4.2) and then extracts two coordinated triads: one that measures distinguishability (three "distance" modes) and one that measures temporal flow (three "time" modes) [30, 29, 36, 37]. Those six modes—defined by gauge-covariant, state-dependent expectations of $\hat{G}_\Lambda$ and its spectral commutator $[\hat{D}, \hat{G}_\Lambda]$—form a tri-axial, background-free chronogeometry on the quantum configuration space $\mathcal{X}_q$ [23, 24, 25, 22]. The result is not merely formal: parallel transport, curvature, and loop operators make the geometry operational (one can "close a loop" and read off holonomy) in the holosymmetric channel (Section 4.1.3), while the spectral leg neatly self-regularises without external cutoffs (cf. Definition 4.428 and Remark thereafter) [45, 36, 37].

It also explains how local, apparently autonomous subsystems emerge without breaking the global, correlator-driven picture. Exact factorisation is generically obstructed, but approximate (FAPP) factorisation holds widely enough to recover familiar dynamics; along the same lines, protected twofold qubit sectors appear as block-diagonalisable limits inside the Fourfold architecture (Section 4.1.5 and Definition 1.32) [22, 30, 29]. All of this is organised in a relational bundle $\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \times \mathcal{F}_x^{\text{time}}$ that stitches local interference rules to global metric structure via the composite tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (Section 4.1.3), and sets the stage for defining emergent proper distance and proper time (Section 5.3.8) [45, 36, 37].

Chapter 5: The Metric and Temporal Tensors

Chapter 5 develops the operator–geometric heart of the programme. First, it defines an *operator-valued emergent metric* by taking the Fréchet second variation (in the strong–operator topology) of the composite triadic distance D^2 between PQS loci (cf. Section 4.11.3 and Definition 5.10), yielding a positive, Hermitian field $\hat{g}_{\mu\nu}(x)$ whose classical avatar $\bar{g}_{\mu\nu}(x) = \langle \overset{\circ}{\mathbf{\Psi}} | \hat{g}_{\mu\nu}(x) | \overset{\circ}{\mathbf{\Psi}} \rangle$ governs the expectation-level geometry (cf. Definitions 5.1 and 5.10 and Section 5.1) [36, 37, 30, 29]. Ultra-locality on spectrally regulated fibres and gauge covariance are made explicit (cf. eqs. (4.11) and (4.303) and Section 4.19.1) [45, 36], while positivity ensures a viable seed for distances and curvature in the emergent configuration space $\mathcal{X}_q$ (cf. Section 5.1) [30, 29].

In parallel, the chapter introduces the *operator-valued temporal curvature tensor* by the same second-variation construction applied to a composite temporal functional T^2, producing $\hat{t}_{\mu\nu}(x)$ with a canonical triadic split (correlational, vacuum, spectral) and with ultra-sub-

Planckian support and gauge covariance (cf. Definitions 5.17 and 5.54 and eq. (4.303)) [36, 37, 30]. Its expectation $\bar{t}_{\mu\nu}(x) = \langle \overset{\circ}{\boldsymbol{\Psi}} | \hat{t}_{\mu\nu}(x) | \overset{\circ}{\boldsymbol{\Psi}} \rangle$ encodes curvature of quantum phase flow (cf. Definition 5.22 and Section 5.1) [23, 24, 25]. Conceptually, $\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \oplus \mathcal{F}_x^{\text{time}}$ underwrites a *relational duality* (cf. eq. (4.302) and Section 1.2.9): distance and phase arise as orthogonal, independent contributors to chronogeometry, unified at the operator level by $\hat{\Sigma}_{\mu\nu} := \hat{g}_{\mu\nu} + \hat{t}_{\mu\nu}$ and at the classical level by $\bar{\Sigma}_{\mu\nu} := \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (cf. Definitions 5.25 and 5.26) [45, 36]. The text distils the physical content of $\bar{\Sigma}_{\mu\nu}$: it is not a Riemannian metric but a total *chronogeometric* response field, from which both distinguishability ("how far apart") and phase-flow ("how out of phase") of nearby configurations can be read (cf. Section 5.1) [36, 37].

From this vantage, causal structure becomes two-layered (cf. Section 5.4): a *hard* kinematic boundary—the effective light cone—emerges from the symmetrized Lorentzian tensor $\bar{g}_{\mu\nu}^{\text{Lor}} := \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}^{\text{sym}}$ (cf. Section 5.4.1 and Definition 5.122) [45], while a *soft* quantum texture inside the cone is governed by $\bar{t}_{\mu\nu}$, potentially including torsion-like effects from its antisymmetric sector and rendering causality state-dependent and dynamical (cf. Section 5.1) [56, 20]. The classical GR limit is recovered by a coarse-graining that discards $\bar{t}_{\mu\nu}$, projecting to a pseudo-Riemannian manifold $\mathcal{M}_{\text{geom}}$ determined solely by $\bar{g}_{\mu\nu}$ (cf. Section 5.3.12) [45, 43, 44]. Operationally, geodesics of $\bar{g}^{\text{Lor}}$ need not coincide with *paths of maximal coherence*, and quantum processes can exhibit directional decoherence anisotropies—diagnostics for experimental tests (cf. Sections 4.12, 4.12.3 and 4.12.5, Definition 4.523, and eq. (4.243)) [23, 24, 25, 22, 53, 51]—before closing with concrete avenues: coupled field equations for $(\bar{g}, \bar{t})$, Bianchi-type identities, invariant diagnostics, and interferometric probes of the temporal sector (cf. Sections 5.1 and 5.4) [45, 22].

Chapter 5 lifts the *relational fibre data* of Chapter 5 into *operator–valued tensors* on $\mathcal{X}_q$—an operator–valued metric $\hat{g}_{\mu\nu}$ and an operator–valued temporal tensor $\hat{t}_{\mu\nu}$—and then takes Born expectations to obtain classical tensor fields $\bar{g}_{\mu\nu}$ and $\bar{t}_{\mu\nu}$. These assemble into the *Unified Relational Chronogeometric Tensor* $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$, which supplies the expectation-level chronogeometry on $\mathcal{X}_q$ (cf. Definitions 5.10, 5.22 and 5.26) [30, 29, 36, 37, 45]. The construction is *gauge-covariant*, *ultra-local* on the spectrally regulated sector, and *operationally complete* at second order (cf. eq. (4.303) and Section 4.19.1) [36, 37, 30, 29, 45].

From fibre to tensors: the $\rightsquigarrow$ mapping. Orthogonal fibre structure. On the regulated sector (cf. eq. (4.303)), the relational bundle fibre at x, $\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \times \mathcal{F}_x^{\text{time}}$ (cf. eq. (4.302)), is treated as a Hilbert direct sum

$$\mathfrak{F}_x \;\cong\; \mathcal{F}_x^{\text{dist}} \oplus \mathcal{F}_x^{\text{time}},$$

with the Fourfold inner product from Section 1.2.9. This orthogonality permits the formation of quadratic functionals and the taking of second variations to define $\hat{g}_{\mu\nu}$ and $\hat{t}_{\mu\nu}$ (cf. Definitions 5.1 and 5.17).

Second variations of composite norms. The tensors arise as Hessians of sectoral squared norms in the coincidence limit $x' \to x$:

- *Metric part:* from the distinguishability norm $D^2(x, x') = \|\vec{d}(x, x')\|_2^2$ (cf. Definitions 5.1 and 5.10).

- *Temporal part:* from the temporal-flow norm $T^2(x,x') = \|\vec{t}(x,x')\|_2^2$ (cf. Definitions 5.17 and 5.22).

Because $\mathcal{F}_x^{\text{dist}}$ and $\mathcal{F}_x^{\text{time}}$ are orthogonal, the resulting tensors contribute independently to the emergent chronogeometry.

Relational duality (distance vs. phase). At the expectation level, $\bar{g}_{\mu\nu}$ and $\bar{t}_{\mu\nu}$ are smooth, symmetric, real $(0,2)$ tensors on $\mathcal{X}_q$, obtained as Born expectations of the corresponding operator–valued Hessians. They encode complementary aspects of the same fibre data—spatial distinguishability and curvature of quantum phase flow (cf. Section 5.1).

The unified chronogeometry and its decompositions. Unified tensor. The expectation tensors are packaged as

$$\bar{\Sigma}_{\mu\nu}(x) \;:=\; \bar{g}_{\mu\nu}(x) \;+\; \bar{t}_{\mu\nu}(x) \quad \text{(cf. Definition 5.26)}.$$

This is the classical carrier of chronogeometric information in the IQR framework.

Triadic split. Each piece admits the canonical triadic decomposition aligned with the correlation/vacuum/spectral axes (Chapter 5),

$$\bar{g}_{\mu\nu} = \bar{g}^{\text{corr}}_{\mu\nu} + \bar{g}^{\text{vac}}_{\mu\nu} + \bar{g}^{\text{spec}}_{\mu\nu}, \qquad \bar{t}_{\mu\nu} = \bar{t}^{\text{corr}}_{\mu\nu} + \bar{t}^{\text{vac}}_{\mu\nu} + \bar{t}^{\text{spec}}_{\mu\nu} \quad \text{(cf. Definition 5.54)}.$$

This preserves functional orthogonality of the three axes at the level of tensor contributions.

Expectation-level relational manifold. The expectation-level manifold is then

$$\mathcal{M}_{\text{rel}} \;:=\; \big(\mathcal{X}_q,\; \bar{g}_{\mu\nu},\; \bar{t}_{\mu\nu}\big),$$

intermediate between the operator-level quantum manifold $\hat{\mathcal{M}}$ and any macroscopic coarse-graining $\mathcal{M}_{\text{geom}}$ (cf. Definition 5.66).

Why the split $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ is canonical.

- **Gauge covariance & ultra-locality.** The sectoral functionals D^2, T^2 are gauge-invariant and supported at the $\mathcal{O}(\ell_{\text{PQS}})$ scale (cf. eq. (4.303)); hence $\hat{g}_{\mu\nu}, \hat{t}_{\mu\nu}$ are gauge-covariant operators with gauge-invariant expectations, suitable as classical geometry on $\mathcal{X}_q$.
- **Operational sufficiency.** Visibility moduli feed $D^2 \to \bar{g}$; phase-slope data feed $T^2 \to \bar{t}$. At second order these Hessians exhaust the observer-independent, gauge-invariant chronogeometric content encoded by the regulated fibre and its connection (cf. Section 4.19.1 and eq. (4.11)).
- **Minimality with room for extensions.** The diagonal sectorization is the minimal choice consistent with IQR semantics; a regulated, gauge-invariant mixed functional $M(x,x') = \langle \vec{d}, \mathsf{K}\,\vec{t}\rangle$ could be introduced to define a third tensor $\bar{m}_{\mu\nu}$, if required by future physics.

Causality and holosymmetric control. A holosymmetric analysis considers families of Lorentzian branch metrics $\{\bar{g}^{\mathrm{Lor}}_{(k)}\}$ along with temporal profiles $\{\bar{t}_{(k)}\}$ [45]. Chapter 5 defines *holosymmetric causal functionals* on $T_x\mathcal{M}_{\mathrm{geom}}$: a micro-causality test $\mathcal{C}^{\mathrm{micro}}_x$, a reach functional $\mathcal{C}^{\mathrm{reach}}_x$, and a temporal profile $\mathcal{T}^{\mathrm{HS}}_x$, built from $\chi_{\mathrm{causal}}\big[\bar{g}^{\mathrm{Lor}}_{(k)\mu\nu}V^\mu V^\nu\big]$ across branches (cf. Definition 5.123) [45, 30, 29]. From these, the *no–signalling and phase invariance* proposition states: if regions A, B are spacelike in the intersection of branch cones $\mathrm{Spacelike}_\cap$, then local observables commute for all holosymmetric phases (φ, θ), and influence is confined to $J^+_\cup(A)$ (the union of future cones); both $\mathrm{Spacelike}_\cap$ and $J^\pm_\cup$ are invariant under holosymmetric phase choices (cf. Proposition 5.152) [22, 30, 29, 45, 23, 24, 25, 20].

Where Chapter 4 enters the pipeline.

1. **Fibre-level primitives (from Chapter 4).** The relational fibre $\mathfrak{F}_x = \mathcal{F}^{\mathrm{dist}}_x \oplus \mathcal{F}^{\mathrm{time}}_x$ and the coordinated triads $\vec{d}, \vec{t}$ along the corr/vac/spec axes are built from the Fourfold correlator and the GNS/emergent setting (Definition 4.9, Sections 1.4.2 and 4.1.3, and eq. (4.302)).

2. **Sectoral norms (Chapter 5).** These fibres are summarised by the quadratic functionals $D^2 = \|\vec{d}\|_2^2$ and $T^2 = \|\vec{t}\|_2^2$, which package distinguishability and temporal response for second-variation analysis (Section 5.1).

3. **Second variations to tensors.** Taking Hessians of D^2 and T^2 yields operator–valued tensors $\hat{g}_{\mu\nu}$ and $\hat{t}_{\mu\nu}$ (Definitions 5.1 and 5.17); Born expectations give the smooth fields $\bar{g}_{\mu\nu}$ and $\bar{t}_{\mu\nu}$ (Definitions 5.10 and 5.22).

4. **Unified chronogeometry.** The expectation tensors assemble into the Unified Relational Chronogeometric Tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ with its corr/vac/spec triadic split, defining the expectation-level relational manifold $\mathcal{M}_{\mathrm{rel}} = (\mathcal{X}_q, \bar{g}, \bar{t})$ (Definitions 5.26, 5.54 and 5.66).

This chain is *self-regularising* (no external cutoffs): finiteness of the sectoral distances/-times implies finiteness of $\hat{g}_{\mu\nu}, \hat{t}_{\mu\nu}$ and their expectations via modal-weight suppression and commutator bounds (Definition 4.428 and Section 4.9.14). Gauge-covariant transport and its path-ordered form control comparisons along curves and around loops (Section 4.19.1 and eq. (4.11)).

Key properties and guarantees.

- **Orthogonal sectors.** The splitting $\mathfrak{F}_x = \mathcal{F}^{\mathrm{dist}}_x \oplus \mathcal{F}^{\mathrm{time}}_x$ ensures clean second-variation constructions and independent sectoral contributions (eq. (4.302), Section 1.2.9, and Definitions 5.1 and 5.17).

- **Expectation-level tensors.** $\bar{g}_{\mu\nu}$ and $\bar{t}_{\mu\nu}$ arise by Born expectation of the operator Hessians of D^2 and T^2, respectively (Definitions 5.10 and 5.22 and Section 5.1).

- **Unified, triadic structure.** $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ carries the minimal split into metric and temporal parts, each with corr/vac/spec decomposition (Definitions 5.26 and 5.54).

- **Gauge covariance and ultra-locality.** The framework is gauge-covariant and ultra-local on the spectrally regulated sector; mixed contributions can be introduced in a regulated, gauge-invariant way if required (eqs. (4.11) and (4.303) and Sections 4.9.14 and 4.19.1).

- **Causal controls.** Holosymmetric causal functionals yield micro-causality and controlled reach across branch cones; a no–signalling theorem holds on the intersection of branch spacelike cones (Definition 5.123 and Proposition 5.152).

The Continuum: Relational Chronogeometry Across Chapters 4 and 5

Chapter 4 lays the algebraic and kinematic groundwork by introducing the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda$ and the admissible Spectral Operator $\hat{D}$ as gauge-covariant primitives (cf. Definitions 4.9 and 4.343) [36, 37, 30, 29]. Their comparison across loci is organised by the operational connection and its path-ordered transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ (cf. Section 4.19.1 and eq. (4.11)) [45, 36]. Within this framework the channel operators $\hat{G}_\Lambda^{\alpha\beta}(x, x')$ inherit Hermiticity and covariance from the Fourfold structure, providing the observer-independent kinematics upon which the emergent configuration space $\mathcal{X}_q$ and all subsequent geometric constructs are built [30, 29].

Chapter 4 packages these primitives into a fibrewise, tri-axial calculus on $\mathcal{X}_q$. The Relational Distinguishability and Temporal fibres collect the three axes of distinguishability $\vec{d} = (d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}})$ and their temporal complements $\vec{t} = (t_{\text{corr}}, t_{\text{vac}}, t_{\text{spec}})$ (cf. Definitions 4.599 and 4.600 and Section 4.11.3) [22, 23, 24, 25, 36, 37]. Composite, gauge-covariant notions of distance and time arise from these axes (cf. Sections 4.10.2, 4.12 and 5.3.8) [45]; for example, t_{corr} is fixed by the correlator's argument with a differential phase-rate 1-form and a node regularisation prescription (cf. Definitions 4.523 and 4.527, eq. (4.243), and Remark 4.524) [23, 24, 25]. The chapter further establishes functional orthogonality and Fréchet independence of the generators (cf. Sections 4.10.1 and 4.11.5) [30, 29],å and proves *self-regularization* of the spectral leg via state-conditioned modal weights—yielding endogenous finiteness and a coherent regularisation principle—together with a relational framework for infrared control (cf. Sections 4.9.7, 4.9.11 and 4.9.13 to 4.9.15) [36, 37, 30, 29, 45, 53, 51].

Chapter 5 takes the fibre-level "ruler and clock" of Chapter 4 and turns them into fields that live everywhere on $\mathcal{X}_q$. Technically, it lifts the fibre data to operator–valued tensors by taking second variations (Hessians) of the sectoral squared norms $D^2 = \|\vec{d}\|_2^2$ and $T^2 = \|\vec{t}\|_2^2$, thereby defining an operator-valued metric $\hat{g}_{\mu\nu}$ and an operator-valued temporal tensor $\hat{t}_{\mu\nu}$ (cf. Definitions 5.1 and 5.17) [36, 37, 30, 29]. These constructions are gauge–covariant and ultra-local on the spectrally regulated sector (eq. (4.303); cf. Definition 4.428) [36, 37], while the operational connection (and its path-ordered transport) tells you how to carry the "ruler and clock" along paths and compare them on loops (Section 4.19.1 and eq. (4.11)) [45]. Taking Born expectations turns the operator responses into smooth, symmetric $(0, 2)$ fields $\bar{g}_{\mu\nu}$ and $\bar{t}_{\mu\nu}$ (cf. Definitions 5.10 and 5.22 and Section 5.1) [30, 29]. Because the relational fibres split orthogonally, $\mathfrak{F}_x = \mathcal{F}_x^{\text{dist}} \oplus \mathcal{F}_x^{\text{time}}$, the distance and time sectors contribute independently to the chronogeometry (cf. eq. (4.302) and Section 1.2.9) [23, 24, 25]. The two expectation fields assemble into the Unified Relational Chronogeometric Tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ with a triadic split aligned to the corr/vac/spec axes (cf. Definitions 5.26 and 5.54), defining the expectation-level relational manifold $\mathcal{M}_{\text{rel}} = (\mathcal{X}_q, \bar{g}, \bar{t})$ (cf. Definition 5.66) [45, 36, 37]. Conceptually, $\bar{\Sigma}_{\mu\nu}$

is a *response* field—like a material's stiffness that changes with state—rather than a fixed Riemannian metric (Section 5.1) [36, 37].

On top of this split, Chapter 5 builds causality and phenomenology. A symmetrised Lorentzian combination $\bar{g}^{\mathrm{Lor}}_{\mu\nu} := \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu}$ draws the kinematic boundary—the effective light cone—while $\bar{t}_{\mu\nu}$ sets the state-dependent "weather" inside the cone (cf. Sections 5.4 and 5.4.1 and Definition 5.122) [45, 20]. Holosymmetric causal functionals and a no-signalling proposition formalise micro-causality and controlled reach across branch cones (cf. Definition 5.123 and Proposition 5.152) [22, 30, 29]. In the macroscopic limit, neglecting $\bar{t}_{\mu\nu}$ recovers the pseudo-Riemannian manifold $\mathcal{M}_{\mathrm{geom}}$ determined by $\bar{g}_{\mu\nu}$ (cf. Section 5.3.12) [43, 44, 45]. Operationally, geodesics of $\bar{g}^{\mathrm{Lor}}_{\mu\nu}$ need not follow paths of maximal coherence, suggesting interferometric diagnostics tied to the triadic time structure and phase/response functionals (Sections 4.12, 4.12.3 and 4.12.5, Definition 4.523, and eq. (4.243)) [23, 24, 25, 22, 53, 51]. In this way, the pipeline that began with the Fourfold correlator and operational transport of Chapter 4 (Sections 1.4.2 and 4.1.3) culminates in Chapter 5's expectation-level chronogeometric and causal structure [30, 29, 36, 37, 45].

Part III: Laws, States and Fundamental Fields

Chapter 6: The Gaiamiti and Tantrakyma Fields

Unified correlator and transport. First, Chapter 6 puts the Fourfold/GNS infrastructure of Chapters 4–5 to work by declaring the *Unified Inter-Modal Correlator* $\hat{\mathbf{G}}_\Lambda(x, x')$ as a 2×2 matrix over the two field channels $\mathbf{A}, \mathbf{B} \in \{\Phi, \Theta\}$ (Gaiamiti and Tantrakyma). Each block $\hat{G}_{\mathbf{AB}}(x, x')$ is expanded in a mode basis $\{\psi^{(\mathbf{A})}_k\}$ and made gauge-covariant by an explicit path-ordered transport $U(x \leftarrow x')$ built from the operational connection; this locks the correlator to the relational parallel transport introduced earlier (Definition 6.4, Section 4.19.1, and eq. (4.11)) [45]. The definition spells out the mode sum and U precisely, so the whole object is state- and connection-covariant from the outset [30, 29, 36, 37].

Relational Levi–Civita calculus on $(\mathcal{X}_q, \bar{\Sigma})$. Second, it *upgrades calculus on* $(\mathcal{X}_q, \bar{\Sigma})$ by defining the *Relational Levi–Civita Connection* $\nabla^{(\mathrm{rel})}$ whose Christoffels are computed from the *composite* chronogeometric tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (not just $\bar{g}$). The formula for $\Gamma^\lambda_{\mu\nu}[\bar{\Sigma}]$ and the induced covariant derivatives on vectors/covectors are given explicitly (Definition 6.7 and eq. (6.22)) [45]. The text is careful about scope: $\nabla^{(\mathrm{rel})}$ lives on the emergent configuration space $\mathcal{X}_q$ and is applied to smooth tensor fields there—the "hierarchy of manifolds" paragraph makes that domain separation exact (Proposition 4.625) [30, 29]. This is what lets the chapter talk cleanly about geodesics and curvature *of the chronogeometry* rather than only of $\bar{g}$.

Measure, action, and dynamical fields. Third, it *chooses the integration measure and builds dynamics*. The *Relational Volume Element* is fixed as

$$d\mu(x) \;=\; \sqrt{-\det \bar{g}^{\mathrm{Lor}}(x)}\, d^d x, \qquad \bar{g}^{\mathrm{Lor}}_{\mu\nu} \;:=\; \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu},$$

so the temporal response tensor $\bar{t}_{\mu\nu}$ affects the measure already at the expectation level (Definition 6.33) [45]. This choice is then used to write action integrals and energy functionals, ensuring that *measure, connection, and correlators* are mutually consistent on the same background-free geometry (Definitions 6.4 and 6.7 and Section 4.19.1) [36, 30, 29]. Concretely, the chapter postulates an *operator-valued Lagrangian density* for the *Dynamical Gaiamiti Field* $\hat{\mathbf{\Phi}}(x)$—treated as a section of $\mathrm{End}(\mathcal{H}_{\mathrm{em}}) \otimes T\mathcal{M}_{\mathrm{vac}}$—with a total covariant derivative (geometric + internal) and an operator-valued inner product g_T on $T\mathcal{M}_{\mathrm{vac}}$ (Section 6.5 and Definition 6.172) [36, 37, 45]. This makes the field-theory part explicitly "relational": both kinematics (∇) and the bundle the field lives in depend on the emergent structures of Chapters 4–5.

Relational Hamiltonian and vacuum. Finally, it *defines the Relational Hamiltonian* $\hat{H}[|\mathbf{\Psi}\rangle]$ by integrating the traces of the correlator blocks against the relational measure, with an explicit split into $\hat{H}_{\Phi}$, $\hat{H}_{\Theta}$, and a mixed $\hat{H}_{\Phi\Theta}$ (Definition 6.54 and eq. (6.109)) [30, 29]. This makes the *state-dependence* of $\hat{H}$ a principled, background-independent feature (since the measure $\sqrt{-\det \bar{g}^{\mathrm{Lor}(\mathbf{\Psi})}(x)}$ is itself state-conditioned, cf. Definition 6.33) [36, 37, 45]. The *Vacuum Manifold* $\mathcal{M}_{\mathrm{vac}}$ is then identified spectrally as the ground-state eigenspace of $\hat{H}$, closing the loop from correlators → geometry → dynamics → vacua (Section 6.1.17 and Definition 6.61) [30, 29]. The text emphasises this non-linear, state-determined eigenproblem as the core "solution concept" for the theory [29].

Compact synthesis. Put compactly: Chapter 6 formalises the *objects of motion on the relational manifold*—a gauge-covariant correlator matrix $\hat{\mathbf{G}}_{\Lambda}$ tying fields to transport, a Levi–Civita calculus built from $\bar{\Sigma}$, a volume form that already "knows" about $\bar{t}$, an operator-valued Lagrangian for $\hat{\mathbf{\Phi}}$, and a state-dependent Hamiltonian whose spectrum *defines* the vacuum geometry [36, 37, 30, 29, 45]. All of these are written so the same composite tensor $\bar{\Sigma}$ plays the starring role in transport ($\Gamma[\bar{\Sigma}]$), measure ($\sqrt{-\det \bar{g}^{\mathrm{Lor}}}$), and energy (via $\hat{H}[|\mathbf{\Psi}\rangle]$), keeping the framework consistently background-free and operational [45, 36, 37].

The Nature of the Fundamental Fields. In the IQR framework, the universe's content is posited to arise from a structured singularity $\hat{\mathbf{\Omega}}(x) = \overset{\circ}{\mathbf{\Lambda}}_{\hat{\mathbf{\Phi}}\hat{\mathbf{\Theta}}}(x)$, evaluated at each locus x of a foundational continuum (Section 6.1) [20]. Geometry (*Gaiamiti*) and matter-like content (*Tantrakyma*) co-arise from this singular source and are explicitly packaged as a single generalized field doublet $\hat{\mathbf{F}}(x) = (\hat{\mathbf{\Phi}}(x), \hat{\mathbf{\Theta}}(x))^{\mathsf{T}}$ on the emergent configuration space $\mathcal{X}_q$ (Definition 6.1) [36, 37, 30, 29]. This packaging is operationally meaningful because the doublet is measured and transported by the *Unified Inter-Modal Correlator* $\hat{\mathbf{G}}_{\Lambda}(x, x')$, a 2×2 block operator over channels $\mathbf{A}, \mathbf{B} \in \{\Phi, \Theta\}$ whose parallel transport is fixed by the path-ordered relational connection $U(x \leftarrow x')$ (Definition 6.4, Section 4.19.1, and eq. (4.11)) [45, 36]. In this sense, $\hat{\mathbf{F}}$ is not merely a formal concatenation: it is the basic field object whose correlations, transport, and responses are already locked to the chronogeometric background produced by the theory itself [36, 37].

Within the doublet, $\hat{\mathbf{\Phi}}(x)$ provides the geometric response that sources admissible distances, durations, and curvatures at expectation level via the composite chronogeometric tensor

$\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$; the associated calculus and measure are governed by the Relational Levi–Civita connection $\nabla^{(\mathrm{rel})}$ and the relational volume element built from $\bar{g}^{\mathrm{Lor}}_{\mu\nu} := \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu}$ (Definitions 6.7 and 6.33) [45]. Complementarily, $\hat{\boldsymbol{\Theta}}(x)$ carries internal symmetries and excitations (charges, flavours, particle-like modes) that propagate on this chronogeometry; their operator-level coupling to geometry is collected in the unified $\hat{\Sigma}$-sector and its expectation $\bar{\Sigma}$ (Definition 5.25) [38, 36, 37]. Conceptually, this is analogous in spirit to electroweak unification—one packages distinct physical aspects into a single field representation—yet here the unification is effected at the level of relational packaging and transport rather than by identifying gauge groups [57, 58, 59, 38, 36, 37]. The upshot is that spacetime structure and internal structure are *co-constituted* from the start, with their interplay made explicit by $\hat{\mathbf{F}}$, $\hat{\mathbf{G}}_\Lambda$, $\nabla^{(\mathrm{rel})}$, and the relational measure (Section 6.1 and Definitions 6.1, 6.4, 6.7 and 6.33) [30, 29, 45, 36, 37].

Etymological Foundations. The names chosen for these fields reflect their roles, drawing from deep linguistic and mythological roots.

Gaiamiti Field ($\hat{\boldsymbol{\Phi}}$)

The name **Gaiamiti** fuses:

- **Gaia** (Γαῖα): The primordial Greek goddess of Earth, the "ever-sure foundation" in Hesiod's *Theogony* [60]. She represents the **primordial ground** or substrate from which structure emerges. She births, separates, advises, and eventually recedes as order matures, embodying both fecundity [61] and the decisive act of separation needed for structure [60]. Her connection to prophecy at Delphi [62] and autochthonous origins [63] reinforces her foundational role. The name itself is likely pre-Greek, suggesting a primordial origin [64, 65].
- **Miti**: From Sanskrit (*miti*), meaning **measure**. It forms the basis of *jyā-miti* ("bowstring-measure"), the classical term for geometry [66]. This highlights geometry as an operational act of relating curves (the world) to straight lines (measurement tools) [34]. This concept spans from practical altar construction (*Śulba-sūtras*) to astronomy [67], eventually yielding terms like *sine* [68]. It signifies the act of rendering relations legible.

Thus, **Gaiamiti** means "measure of the ground" or "Gaia's geometry," signifying the field whose correlations draw out and make legible the geometric structure from the primordial substrate.

Definition 6.2: The Gaiamiti Field The field $\hat{\boldsymbol{\Phi}}(x)$ is formally defined as the first component of $\hat{\mathbf{F}}(x)$, a Hermitian, operator-valued field generating the emergent metric $\bar{g}_{\mu\nu}(x)$ and temporal tensors $\bar{t}_{\mu\nu}(x)$. It admits a modal decomposition:

$$\hat{\boldsymbol{\Phi}}(x) = \sum_{\alpha} \hat{\Phi}_\alpha(x)\, |\alpha\rangle_x$$

over the dialectical modes $\alpha \in \{0, 1, p, s\}$.

Apeiron (ἄπειρον) (Section 6.1) This term, meaning "un-limited" or "indefinite," is redeployed to denote the **quantum pulse of the Gaiamiti field**: the minimal, predicate-free

event of givenness before measure articulates it. It draws on Anaximander's *archē* [69, 70, 71], the Pythagorean opposition of Limit (*peras*) and Unlimited (*apeiron*) [72], and Aristotle's potential infinite [71, 73]. In this framework, it signifies a discrete, pre-metric, rhythmic pulse articulated by measure (Section 6.1).

Tantrakyma Field ($\hat{\mathbf{\Theta}}$). The name **Tantrakyma** combines:

- **Tantra** (तन्त्र): From Sanskrit root $\sqrt{tan}$ ("to stretch, weave") + suffix *-tra* ("instrument") [66]. It primarily means the **warp** of a fabric or a **loom**, extending to mean framework, system, rule, or doctrine. It became a designation for scriptural corpora in Śaiva, Śākta, Vaiṣṇava, and Buddhist traditions from the mid-first millennium CE [74, 75, 76, 77, 78, 79]. The Tibetan translation *rgyud* ("continuity") emphasizes the unbroken transmission, akin to warp threads [75].
- **Kyma** (κῦμα): The classical Greek word for **wave** or swell, from PIE root *keue-* ("to swell, curve") [80, 81]. It signifies dynamic form, embodying both pattern and flux, central to Heraclitus' philosophy (*panta rhei*) [70]. Its modern legacy includes terms like cymatics, kymograph, myokymia, cyma (architecture), and cyme (botany) (Section 6.1).

Therefore, **Tantrakyma** signifies a "woven-wave framework": a field where wave-like excitations ($\hat{\Theta}_\beta(x)$ modes) act as threads woven upon a structural warp (internal symmetries), generating coherent particle content and conserved quantum numbers.

Definition 6.3: The Tantrakyma Field The field $\hat{\mathbf{\Theta}}(x)$ is the second component of $\hat{\mathbf{F}}(x)$. It's a Hermitian, operator-valued field whose excitations correspond to emergent particles and internal symmetries yield conserved quantities. It also has a modal decomposition:

$$\hat{\mathbf{\Theta}}(x) = \sum_\beta \hat{\Theta}_\beta(x)\,|\beta\rangle_x$$

where $\hat{\Theta}_\beta(x)$ describes internal excitation states.

Kymon: The fundamental quantum of the Tantrakyma field, named from *Kyma* + suffix *-on*. It represents a wave-like excitation propagating on the Gaiamiti-generated geometry, carrying charges determined by $\hat{\mathbf{\Theta}}$'s symmetries [82, 14].

Chrono-Kymon: An excitation linked to the temporal structure ($\bar{t}_{\mu\nu}$), specifically a spin-1 mediator of temporal torsion, influencing how clocks and causal order knit together. It represents a quantum twist in the local flow of time, distinct from spin-2 gravitons [83, 11].

Dual Roles and Unification. The Gaiamiti $\left(\hat{\mathbf{\Phi}}\right)$ and Tantrakyma $\left(\hat{\mathbf{\Theta}}\right)$ fields play distinct yet complementary roles within the unified singularity $\hat{\mathbf{\Omega}} = \overset{\circ}{\Lambda}_{\hat{\mathbf{\Phi}}\hat{\mathbf{\Theta}}}$ (Section 6.1), and are operationally packaged by the generalized field doublet $\hat{\mathbf{F}}(x)$ (Definition 6.1).

- **Gaiamiti.** The architect of geometry, establishing admissible distance, duration, and curvature at expectation level through the chronogeometric response $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (Definition 5.26). Its self-correlations $\hat{G}_{\Phi\Phi}$ are the geometric block of the Unified Inter-Modal Correlator and "weave" the spacetime fabric in a gauge-covariant way (Definition 6.4, Section 4.19.1, and eq. (4.11)).

- **Tantrakyma.** The source of flavour/charge and matter-like structure, carrying internal excitations that propagate on the chronogeometry. These modes $\hat{\Theta}_\beta$ live in the excitation fibre orthogonal to geometric deformations and are represented by the dynamical Tantrakyma field section (Definitions 6.141 and 6.142).

This relationship is likened to a *celestial symphony*: Gaiamiti provides the harmonic space (geometry) while Tantrakyma traces the melodic figures (matter content) (Section 6.1).

Correlations and Dynamics. The interplay between Gaiamiti and Tantrakyma is encoded by the *Unified Inter-Modal Correlator* $\hat{\mathbf{G}}_\Lambda(x,x')$, a 2×2 matrix over channels $\mathbf{A},\mathbf{B}\in\{\Phi,\Theta\}$ acting on the generalized field doublet $\hat{\mathbf{F}}$ (Definitions 6.1 and 6.4):

$$\hat{\mathbf{G}}_\Lambda(x,x') \;:=\; \begin{pmatrix} \hat{G}_{\Phi\Phi}(x,x') & \hat{G}_{\Phi\Theta}(x,x') \\ \hat{G}_{\Theta\Phi}(x,x') & \hat{G}_{\Theta\Theta}(x,x') \end{pmatrix}.$$

Each block $\hat{G}_{\mathbf{AB}}(x,x')$ further resolves over the 4×4 dialectical modes (α,β) as operator products of the form $\hat{A}^\dagger_\alpha(x)\,U(x\leftarrow x')\,\hat{B}_\beta(x')$, where $U(x\leftarrow x')$ is the path-ordered relational transport generated by the operational connection (Sections 4.19.1 and 6.1.1 and eq. (4.11)). This construction makes $\hat{\mathbf{G}}_\Lambda$ manifestly state- and connection-covariant from the outset.

The diagonal blocks play distinct roles. The *geometric block* $\hat{G}_{\Phi\Phi}$ encodes self-correlations of Gaiamiti and, at expectation level, feeds into the chronogeometric response $\bar{\Sigma}_{\mu\nu}=\bar{g}_{\mu\nu}+\bar{t}_{\mu\nu}$ that structures distance, duration, and curvature (Definition 5.26). The *matter block* $\hat{G}_{\Theta\Theta}$ captures self-correlations of Tantrakyma governing propagation and internal interactions on that chronogeometry (Definition 6.142). The off-diagonal *interaction blocks* $\hat{G}_{\Phi\Theta}$ and $\hat{G}_{\Theta\Phi}$ implement geometry–matter coupling in both directions—schematically "matter tells geometry how to curve" and "geometry tells matter how to move"—and are evaluated in the same gauge-covariant, transported form (Definition 6.4 and Section 4.19.1).

Dynamically, these correlations are propagated and compared using connections and measures compatible with the emergent geometry. Covariant differentiation is performed with the Relational Levi–Civita connection $\nabla^{(\mathrm{rel})}$ built from the composite tensor $\bar{\Sigma}$ (Definition 6.7), while action and energy functionals integrate correlator traces against the relational volume element $d\mu(x)=\sqrt{-\det \bar{g}^{\mathrm{Lor}}(x)}\,d^dx$, with $\bar{g}^{\mathrm{Lor}}_{\mu\nu}:=\bar{g}_{\mu\nu}+\bar{t}^{\mathrm{sym}}_{\mu\nu}$ (Definition 6.33). In particular, the Relational Hamiltonian $\hat{H}$ decomposes into geometric, matter, and mixed parts $\hat{H}_\Phi+\hat{H}_{\Phi\Theta}+\hat{H}_\Theta$, making the block structure of $\hat{\mathbf{G}}_\Lambda$ operational in energy accounting (Definition 6.54 and eq. (6.109)).

Relational Levi–Civita derivative. On the emergent configuration space $\mathcal{X}_q$ (cf. Proposition 4.625), the theory singles out a unique torsion-free connection $\nabla^{(\mathrm{rel})}$ that is compatible with the full *chronogeometric tensor* $\bar{\Sigma}_{\mu\nu}=\bar{g}_{\mu\nu}+\bar{t}_{\mu\nu}$ (cf. Definitions 5.26 and 6.7). Its Christoffel symbols are computed from the composite $\bar{\Sigma}$,

$$\Gamma^\lambda_{\mu\nu}[\bar{\Sigma}] \;=\; \tfrac{1}{2}\,\bar{\Sigma}^{\lambda\rho}\Big(\partial_\mu\bar{\Sigma}_{\nu\rho}+\partial_\nu\bar{\Sigma}_{\mu\rho}-\partial_\rho\bar{\Sigma}_{\mu\nu}\Big).$$

Here $\bar{\Sigma}^{\mu\nu}$ denotes the inverse of $\bar{\Sigma}_{\mu\nu}$ (cf. Definition 6.24 and eq. (6.22)).

Because $\nabla^{(\mathrm{rel})}$ is metric-compatible with $\bar{\Sigma}$, parallel transport, curvature, and geodesics are all defined with respect to the *composite* response, so geodesic motion is influenced both by the metric part $\bar{g}_{\mu\nu}$ and by gradients of the temporal tensor $\bar{t}_{\mu\nu}$ (see Definition 6.7 and references therein, e.g. [7, 84, 85]).

Relational volume element. The invariant integration measure on $\mathcal{X}_q$ is determined by the *Effective Lorentzian Metric* $\bar{g}^{\mathrm{Lor}}_{\mu\nu} := \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu}$ (cf. Definition 5.77 and Section 6.1.5):

$$d\mu(x) \;:=\; \sqrt{-\det \bar{g}^{\mathrm{Lor}}_{\mu\nu}(x)}\, d^d x,$$

as stated in Definition 6.33. This measure is the one used in action and energy functionals [7]; crucially, its dependence on both the geometric curvature $\bar{g}_{\mu\nu}$ and the temporal structure $\bar{t}^{\mathrm{sym}}_{\mu\nu}$ makes the weighting of fields intrinsically state-responsive, with potential phenomenological implications in extreme regimes [86, 87, 88, 89, 1].

The Vacuum Manifold. The vacuum is characterised as a state of *minimal relational complexity*, formulated in parallel variational and spectral terms (Section 6.1.8). In the variational picture, one evaluates the *relational action functional* on a state $|\mathbf{\Psi}\rangle \in \mathcal{H}_{\mathrm{em}}$ (cf. Definition 4.287) using the state-conditioned measure built from $\bar{\Sigma}^{(\mathbf{\Psi})}_{\mu\nu}(x) := \langle \mathbf{\Psi}|\hat{\Sigma}_{\mu\nu}(x)|\mathbf{\Psi}\rangle$ (Definitions 5.25 and 6.33):

$$S[|\mathbf{\Psi}\rangle] := \int_{\mathcal{X}_q} d\mu^{(\mathbf{\Psi})}(x)\, \mathrm{Tr}\Big(\langle \mathbf{\Psi}|\hat{\mathbf{G}}_\Lambda(x,x)|\mathbf{\Psi}\rangle \Big),$$
$$d\mu^{(\mathbf{\Psi})}(x) := \sqrt{-\det \bar{g}^{\mathrm{Lor}(\mathbf{\Psi})}(x)}\, d^d x.$$

See Definitions 6.4 and 6.33 and Section 6.1.10.

The trace $\mathrm{Tr}(\cdot)$ aggregates over field channels (Φ, Θ) and their dialectical modes, so that S encompasses geometric, matter, and interaction contributions in a single expression (cf. the sectoral decompositions $S_\Phi, S_\Theta, S_{\Phi\Theta}$ and Definitions 6.4 and 6.172).
In the spectral picture, the *Relational Hamiltonian* is defined so that its expectation value coincides with the action—this is the variational–spectral equivalence (Definition 6.54):

$$\langle \mathbf{\Psi}|\hat{H}|\mathbf{\Psi}\rangle \;=\; S[|\mathbf{\Psi}\rangle], \qquad \hat{H}[|\mathbf{\Psi}\rangle] \;:=\; \int_{\mathcal{X}_q} d\mu^{(\mathbf{\Psi})}(x)\, \mathrm{Tr}_{\mathrm{op}}\Big(\hat{\mathbf{G}}_\Lambda(x,x)\Big),$$

with the blockwise split $\hat{H} = \hat{H}_\Phi + \hat{H}_{\Phi\Theta} + \hat{H}_\Theta$ made explicit in eq. (6.109). The dependence of $d\mu^{(\mathbf{\Psi})}$ on $\bar{g}^{\mathrm{Lor}}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu}$ (Definition 6.33) renders $\hat{H}$ intrinsically state-conditioned.
The *Vacuum Manifold* $\mathcal{M}_{\mathrm{vac}}$ is then the set of normalised states that minimise S (variational view) or, equivalently, the ground-state eigenspace of $\hat{H}$ (spectral view) (Section 6.1.17 and Definition 6.61):

$$\mathcal{M}_{\mathrm{vac}} \;:=\; \Big\{ |\mathbf{\Psi}_{\mathrm{vac}}\rangle \in \mathcal{V}_0 \;\Big|\; \langle \mathbf{\Psi}_{\mathrm{vac}}|\mathbf{\Psi}_{\mathrm{vac}}\rangle = 1 \Big\}, \qquad \mathcal{V}_0 = \ker\Big(\hat{H} - E_0 \mathbb{I}_{\mathrm{em}}\Big),\; E_0 = \inf \mathrm{spec}(\hat{H}).$$

Within this manifold, a particular *Quantum Holo-State* $|\overset{\circ}{\mathbf{\Psi}}\rangle$ is selected to describe our universe (cf. Section 6.1.17), closing the loop from correlators → geometry → dynamics → vacua.

Operator Algebra and Field Definitions. The framework uses an algebraic approach, defining observables abstractly and then realizing them via the GNS construction.

- **Algebra of Observables $\mathcal{A}$:** The foundational C*-algebra (Section 1.4.1).
- **GNS Construction:** Generates the emergent Hilbert space $\mathcal{H}_{\text{em}}$, representation $\pi^{\mathring{\Psi}}$, and cyclic vector $|\mathring{\Psi}\rangle$ from $\mathcal{A}$ and the holo-state functional $\omega^{\mathring{\Psi}}$ (Definition 1.34).
- **Algebra of Endomorphisms** $\text{End}(\mathcal{H}_{\text{em}})$**:** The concrete arena of bounded linear operators $\mathcal{B}(\mathcal{H}_{\text{em}})$ on the emergent Hilbert space, forming a unital Banach $*$-algebra (likely C*-algebra) (Definition 6.111, Definition 6.112, Definition 6.113). $\pi^{\mathring{\Psi}}$ maps $\mathcal{A}$ into this space (Section 6.1.28).

Fluctuations around the vacuum are described using the tangent bundle:

Operator–theoretic tangent bundle of the vacuum. At a vacuum state $|\Omega\rangle \in \mathcal{M}_{\text{vac}}$ (cf. Remark 6.91), the operator–theoretic tangent fibre is taken to be

$$T_{|\Omega\rangle}\mathcal{M}_{\text{vac}} \;=\; \Big\{\, |V\rangle \in \mathcal{V}_0 \;\Big|\; \text{Re}\,\langle\Omega|V\rangle = 0 \Big\},$$

namely the space of infinitesimal, energy-preserving deformations $|V\rangle$ that are physically distinct from the vacuum (orthogonal in the real part) (Definition 6.90). This space is equipped with the inner product $g_T(|V\rangle, |W\rangle) := \langle V|W\rangle_{\mathcal{H}_{\text{em}}}$, which provides the canonical metric on vacuum tangents (Definition 6.104).

Dynamical Gaiamiti field. The geometric response is encoded by a smooth operator-valued section $\hat{\mathbf{\Phi}}(x)$ of the bundle $\text{End}(\mathcal{H}_{\text{em}}) \otimes T\mathcal{M}_{\text{vac}}$ over $\mathcal{X}_q$; locally one has $\hat{\mathbf{\Phi}}(x) \in \text{End}(\mathcal{H}_{\text{em}}) \otimes T_{|\Omega(x)\rangle}\mathcal{M}_{\text{vac}}$. Thus $\hat{\mathbf{\Phi}}(x)$ acts as a quantum–geometric deformation operator anchored to the vacuum-tangent directions at the point x (Definition 6.118; cf. also Section 6.5 and Definition 6.172).

Excitation fibre and Dynamical Tantrakyma field. Orthogonally to the geometric tangents, the excitation fibre at x is

$$\mathcal{E}_{\text{exc}}(x) \;=\; \big(T_{|\Omega(x)\rangle}\mathcal{M}_{\text{vac}}\big)^{\perp},$$

which collects matter-like (internal) directions in state space (Definition 6.141). The corresponding field $\hat{\mathbf{\Theta}}(x)$ is an operator-valued section of $\text{End}(\mathcal{H}_{\text{em}}) \otimes \mathcal{E}_{\text{exc}}$ over $\mathcal{X}_q$, governing the propagation of excitations that are orthogonal to geometric deformations (Definition 6.142). In practice, $\hat{\mathbf{\Phi}}$ and $\hat{\mathbf{\Theta}}$ are coupled and transported jointly through the Unified Inter-Modal Correlator, ensuring gauge-covariant comparison across points of $\mathcal{X}_q$ (Definition 6.4, Section 4.19.1, and eq. (4.11)).

Bundle-Theoretic Formulations (Section 6.4)

- $\hat{\mathbf{\Phi}}(x) = \sum_{i=1}^{r} \hat{\Phi}^i(x)\,|e_i(x)\rangle$ in a tangent space basis $\{|e_i(x)\rangle\}$. $\hat{\Phi}^i$ are operator-valued amplitudes for geometric deformation modes.

- $\hat{\mathbf{\Theta}}(x) = \sum_{\alpha,\beta} \theta^{\alpha\beta}(x)\, |\alpha\rangle_x \langle\beta|_x$ in the dialectical basis. $\theta^{\alpha\beta}$ govern internal dynamics and mixing.

Dual Roles (Summary): $\hat{\mathbf{\Phi}}$ sources geometric observables (apeiron, graviton). $\hat{\mathbf{\Theta}}$ sources matter observables (kymons, particle species, gauge groups via symmetries).

Action and dynamics of the Gaiamiti field. The dynamics of the geometric response are encoded in an operator-valued Lagrangian density that contracts the composite chronogeometric tensor with a vacuum-tangent inner product on covariant derivatives of the field (Section 6.5 and Definition 6.172):

$$\mathcal{L}_\Phi(x) \;=\; \mathrm{Tr}\Big\{ \bar{\Sigma}^{\mu\nu}(x)\, g_T\Big(\nabla_\mu \hat{\mathbf{\Phi}}(x), \nabla_\nu \hat{\mathbf{\Phi}}(x)\Big) + \mathcal{V}_\Phi\Big(\hat{\mathbf{\Phi}}(x)\Big)\Big\}\,.$$

Here $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ is the expectation-level chronogeometric tensor (Definition 5.26), g_T is the canonical inner product on the operator-theoretic vacuum tangents (Definition 6.104), and $\mathcal{V}_\Phi$ encodes self-interactions. The sectoral action has two equivalent guises: fundamentally as a correlator trace integrated with the state-dependent measure,

$$S_\Phi[|\mathbf{\Psi}\rangle] = \int_{\mathcal{X}_q} d\mu^{(\mathbf{\Psi})}(x)\, \mathrm{Tr}\Big(\langle \mathbf{\Psi}|\hat{G}_{\Phi\Phi}(x,x)|\mathbf{\Psi}\rangle\Big).$$

See Definitions 6.4 and 6.33 and Section 6.1.10.

and operationally as the Lagrangian integral

$$S_\Phi[\hat{\mathbf{\Phi}}] \;=\; \int_{\mathcal{X}_q} d\mu(x)\; \mathcal{L}_\Phi(x) \quad (\textit{Definitions } 6.33 \textit{and } 6.174).$$

Self-consistency is built in: the $\bar{\Sigma}_{\mu\nu}$ that contracts the kinetic term is itself sourced by $\hat{\mathbf{\Phi}}$ through the holo-state expectation (Section 6.5 and Definition 5.26).

Covariant structure and the operator bundle connection. The total covariant derivative splits into a base-manifold piece and an internal (bundle) piece (Definition 6.184):

$$\nabla_\mu \hat{\mathbf{\Phi}} \;=\; \nabla^{(\mathrm{rel})}_\mu \hat{\mathbf{\Phi}} \;+\; D_\mu \hat{\mathbf{\Phi}}, \qquad D_\mu \;=\; \partial_\mu + i\,[\mathcal{A}_\mu(x), \cdot\,].$$

The base connection $\nabla^{(\mathrm{rel})}$ is the torsion-free, $\bar{\Sigma}$-compatible Relational Levi–Civita derivative acting on $\mathcal{X}_q$ (Definition 6.7 and Proposition 4.625), while $\mathcal{A}_\mu(x)$ is the Hermitian operator bundle connection arising intrinsically from the algebra of observables via the GNS representation (Definition 6.192 and Remark 6.198). This $\mathcal{A}_\mu$ is universal—acting on both $\hat{\mathbf{\Phi}}$ and $\hat{\mathbf{\Theta}}$ (Remark 6.200)—and governs gauge-covariant parallel transport (cf. the operational connection and its path-ordered transport $U(x \leftarrow x')$ in Section 4.19.1 and eq. (4.11)). Its sectoral quanta (the *mition* in the Gaiamiti sector and the *tantron* in the Tantrakyma sector) are discussed in Remark 6.201, with masses generated via a BEH-type mechanism (Remark 6.205).

Symmetry considerations. Within the relational framework, symmetry is assessed at two levels: the *law level*—the invariances of the relational action and Hamiltonian—and the *state level*—the invariances of vacua and excitations that inhabit the vacuum manifold. Spontaneous symmetry breaking (SSB) occurs when the relational action $S[|\mathbf{\Psi}\rangle]$ and the Relational Hamiltonian $\hat{H}$ possess a symmetry G (Definitions 6.33 and 6.54) that is not shared by the selected vacuum $|\mathbf{\Psi}_{\mathrm{vac}}\rangle \in \mathcal{M}_{\mathrm{vac}}$ (Section 6.1.17 and Definition 6.61). The resulting vacuum degeneracy is organised by the coset G/H, and the tangential excitations along these flat directions manifest as Nambu–Goldstone modes living in the operator–theoretic tangent bundle $T\mathcal{M}_{\mathrm{vac}}$ with inner product g_T (Definitions 6.90 and 6.104; see also [90, 91, 82, 92, 93, 94]). When the relevant symmetry is gauged, the Brout–Englert–Higgs (BEH) mechanism operates: the universal operator bundle connection $\mathcal{A}_\mu$ (Definition 6.192 and Remark 6.200) reorganises the spectrum so that gauge quanta (mition/tantron) acquire mass (Remarks 6.201 and 6.205; cf. [95, 96, 97, 98, 99]), with familiar low-dimensional constraints [100, 101].

Emergent (asymmetry-induced) symmetry refers to situations where the infrared theory exhibits a larger symmetry H_{IR} than is present microscopically G_{UV} [82, 14, 102]. In the present setting, such enhancement can be diagnosed directly in the block structure and transport of the Unified Inter-Modal Correlator $\hat{\mathbf{G}}_\Lambda$ (Definition 6.4 and Section 4.19.1): symmetry-breaking operators may become RG-irrelevant in the correlator's off-diagonal entries, or descend to accidental invariants in the effective Lagrangian density $\mathcal{L}_\Phi$ (Definition 6.172). At the same time, the relational measure $d\mu = \sqrt{-\det \bar{g}^{\mathrm{Lor}}}\, d^d x$ (Definition 6.33) weights configurations in a way that can suppress symmetry-violating responses of $\bar{t}_{\mu\nu}$ relative to $\bar{g}_{\mu\nu}$, yielding an effectively more symmetric infrared chronogeometry. Standard diagnostics—scaling suppression, anomaly consistency [103], approach to fixed-point structure—carry over, now stated in terms of $\hat{\mathbf{G}}_\Lambda$, $\mathcal{L}_\Phi$, and the state-dependent background $\bar{\Sigma}_{\mu\nu}$.

Weaving the two arrows. Many systems realise both tendencies: microscopic asymmetries are diluted along the flow to the infrared (emergence), and the resulting symmetric infrared law is then *spontaneously* broken by the choice of vacuum (SSB). In our notation, the law-level arrow is tracked by the evolution of the correlator blocks and couplings in $\mathcal{L}_\Phi$ (Definitions 6.4 and 6.172) together with the compatible covariant calculus $\nabla^{(\mathrm{rel})}$ (Definition 6.7); the state-level arrow is read off from order parameters living on $T\mathcal{M}_{\mathrm{vac}}$ and the pattern of NG directions inside $\mathcal{M}_{\mathrm{vac}}$ (Definitions 6.61 and 6.90). The 2×2 "Laws vs. States'' matrix in table 6.1 organises these possibilities and their diagnostics, keeping clear which effects are due to changes in the effective *laws* versus choices of *states*.

BRST quantisation and gauge redundancy. Gauge invariance is treated as a redundancy of description by promoting the field space to include ghosts, anti-ghosts, and auxiliary fields and endowing it with a nilpotent BRST charge $\hat{Q}_{\mathrm{BRST}}$ satisfying $\hat{Q}^2_{\mathrm{BRST}} = 0$. Physical states are identified with the ghost-number–zero cohomology, $\mathcal{H}_{\mathrm{phys}} = H^0(\hat{Q}_{\mathrm{BRST}})$, so that gauge-equivalent configurations differ by BRST-exact vectors and are projected out (*Kugo–Ojima* quartet mechanism for unitarity; see [104, 105, 106, 107, 108, 91, 82]). In our setting, this cohomology is taken inside the emergent Hilbert space $\mathcal{H}_{\mathrm{em}}$ and is compatible with the relational covariant calculus $\nabla^{(\mathrm{rel})}$ and the state-dependent integration measure $d\mu = \sqrt{-\det \bar{g}^{\mathrm{Lor}}}\, d^d x$ (Definitions 6.7 and 6.33), so that BRST invariance is formulated directly on

$(\mathcal{X}_q, \bar{\Sigma})$.

Gauge fixing appears as a BRST-exact deformation of the action, $\delta S = \zeta\Psi$ with $\zeta(\cdot) = \{\hat{Q}_{\mathrm{BRST}}, \cdot\}$, which preserves the cohomology class of observables. Accordingly, expectation values of BRST-invariant operators are independent of gauge parameters, as captured by the *Nielsen identity* and the *gauge-fixing exactness principle* (Proposition 6.214 and Principle 6.1). Within the relational framework, the universal operator bundle connection $\mathcal{A}_\mu$ that enters the internal part of the covariant derivative $D_\mu = \partial_\mu + i[\mathcal{A}_\mu, \cdot]$ (Definitions 6.184 and 6.192) is thus fixed only up to BRST-exact choices; "Higgsing'' is not literal gauge SSB, since the would-be Goldstone directions are BRST-exact and removed from $\mathcal{H}_{\mathrm{phys}}$ (Proposition 6.213).

The chapter relates these consistency conditions to the HSP viability criteria: *Stage I* viability (self-coherence of the description) is equivalent to BRST consistency—nilpotency, BRST-invariant dynamics, and absence of gauge anomalies (Principle 6.2 and Proposition 6.217). Operationally, this means the Unified Inter-Modal Correlator $\hat{\mathbf{G}}_\Lambda$, the relational derivative $\nabla^{(\mathrm{rel})}$, and the measure $d\mu$ (Definitions 6.4, 6.7 and 6.33) can be chosen so that all gauge-variant contributions are BRST-exact, while the cohomology classes furnish the gauge-invariant observables and states on the relational manifold.

Duality, quadrants, and holosymmetry. The chapter links the Axiom of Duality to the quadrant structure used for symmetry assessment (see table 6.1). Starting from the duality object and its status lift $\Delta_{\mathcal{C}}$ (Definitions 6.220 and 6.221), one obtains commuting involutions Δ_{Law} and Δ_{State} acting on the law/state symmetry predicates (Definition 6.224). Their $\mathbb{Z}_2 \times \mathbb{Z}_2$ action generates four quadrants—$(\mathsf{Th}, \mathsf{Th})$,$(\mathsf{Th}, \mathsf{AntiTh})$,$(\mathsf{AntiTh}, \mathsf{Th})$,$(\mathsf{AntiTh}, \mathsf{AntiTh})$—which follow from the commuting-lifts result and are organised by the quadrant schema (Proposition 6.225 and Theorem 6.231) [52, 30, 29]. These quadrants correspond, respectively, to the Unbroken, SSB, Emergent, and Explicit–Breaking regimes (Corollary 6.232) [52, 109].

For gauge theories, a cohomological reading is provided: BRST maps the predicates to statements about cohomology classes and anomaly filters, aligning duality with the quartet structure (Remark 6.226, Proposition 6.227, and Corollary 6.228) [52, 109, 110, 111]. In short, duality supplies the algebraic backbone, while the quadrant taxonomy records where symmetry resides—in the *laws* or in the *states* [29].

On top of this algebraic scaffold, the chapter introduces a holosymmetric meta-layer based on two-path interferometry. Law-coherence and state-coherence are captured by functionals Λ_{law} and Λ_{state} that are defined in a parameter-agnostic manner (Definitions 6.237 and 6.238) and evaluated directly in the physical cohomology $\mathcal{H}_{\mathrm{phys}}$. They are gauge-parameter independent (Nielsen-type control; Lemma 6.243), respect the triadic channel split (functoriality with the corr/vac/spec decomposition; Lemma 6.247), and preserve causal cones in the holosymmetric sense (Lemma 6.248) [52, 30, 29, 45]. Crucially, overlaying these diagnostics does not change a system's quadrant membership (Proposition 6.251); instead, it furnishes operational signatures—interference visibilities and phase responses—that distinguish the four regimes (Theorem 6.253, table 6.2) [22, 23, 24, 25]. Thus holosymmetric interferometry supplies an experimentally legible veneer over the duality–quadrant architecture, cleanly separating law-level coherence from state-level order (see table 6.1).

Table 1: Symmetry–Asymmetry Permutations Matrix: Laws vs. States

Laws / World (State)	**Symmetry of World (State)**	**Asymmetry of World (State)**
Symmetry of Law	**I. Unbroken (symmetry preserved)** Unique symmetric vacuum (thermodynamic limit); order parameter = 0; Ward identities exact. Topological/SPT structure may still distinguish phases.	**II. Spontaneous Symmetry Breaking (SSB)** Degenerate vacua related by the symmetry; nonzero order parameter; Nambu–Goldstone modes for broken *global* continuous generators (gauge case diagnosed via gauge-invariant observables).
Asymmetry of Law	**III. Emergent / Accidental Symmetry** IR (effective-law) exhibits enlarged symmetry via RG irrelevance or EFT power suppression; symmetry-violating effects shrink with scale.	**IV. Explicit Breaking (no SSB)** Asymmetric couplings select a unique ground state; no Goldstones. Residual subgroups may remain; responses track the breaking terms.

Notes (cf. table 6.1): (i) "Gauge symmetry" is a redundancy; BEH/Higgs phases are diagnosed by gauge-invariant features (massive vectors, screening), not literal gauge SSB. (ii) Topological/SPT structure can live in quadrant I (symmetry preserved) and should be diagnosed by nonlocal/torsion-like invariants rather than order parameters.

Scale-aware analysis strategy. The chapter closes with a practical programme for analysing phenomena across the four symmetry quadrants that is explicitly scale-aware. First, *scale-tagging* is introduced by combining a UV bandlimit and an IR window: a spectral projector $P_x(\lambda_{\mathrm{UV}})$ selects modes below a local cutoff λ_{UV} (Definition 6.278 and Proposition 6.279), while an IR window $K_{\mathrm{IR}}^{(\ell)}$ of range ℓ implements coarse graining (Definitions 6.280 and 6.289 and Propositions 6.281 and 6.290). Together these define a *band functor* that enforces coherent self-regularisation and the reciprocal resolution trade-off between λ_{UV} and ℓ (Definition 6.282 and Proposition 6.283). With this structure in hand, the theory formulates *scale-tagged* actions, field equations, and Ward identities—Euler–Lagrange equations projected by $P_x(\lambda_{\mathrm{UV}})$ and convolved by $K_{\mathrm{IR}}^{(\ell)}$ (Definition 6.293 and Proposition 6.294), and conserved relations that remain valid after band restriction (Definition 6.295 and Proposition 6.296). The outcome is a family of UV/IR-consistent dynamical statements that can be compared across scales without leaving the relational framework.

Robustness is certified by a *plateau criterion*. A physical claim—such as a mode identification or an effective coupling—is accepted only if it is stable within tolerance $\varepsilon_{\mathrm{tol}}$ across a plateau region in the two-parameter scale space $(\lambda_{\mathrm{UV}}, \ell)$, quantified by small log-derivatives with respect to both scale knobs (Definition 6.297 and Proposition 6.298). Crucially, plateau assessments are *gauge-parameter independent*: the Nielsen-type control shows that admissible variations of gauge-fixing do not spoil plateau stability (Proposition 6.299 and Corollary 6.265). Hence, plateau-qualified statements have operational meaning that does not depend on auxiliary gauge choices.

Finally, a *quadrant traversal strategy* organises concrete analyses in each of the symmetry quadrants (QI–QIV). One proceeds from the variational backbone—scale-tagged actions and projected equations of motion (Definition 6.293 and Proposition 6.294) together with Ward identities (Definition 6.295 and Proposition 6.296)—to linear response (propagators) and then to holosymmetric, two-path diagnostics of law- and state-coherence, Λ_{law} and Λ_{state} (Definitions 6.237 and 6.238). At every step, mode tagging is treated as provisional until plateau stability and BRST consistency are verified; the procedure is spelled out quadrant-by-quadrant in Section 6.12.5. To keep the workflow auditable, the chapter recommends maintaining *practical ledgers*—explicit records of the chosen $(\lambda_{\mathrm{UV}}, \ell)$, gauges, and diagnostic outcomes—throughout the analysis (Section 6.12.7).

The objects and the holosymmetric lift.

Triadic channelization. Work with three BRST-closed channel projectors $\{\Pi_\alpha\}_{\alpha\in\{\mathrm{corr,vac,spec}\}}$ of ghost number 0. These projectors implement the channel split used throughout: they are the projectors that define the channel-restricted visibilities (cf. the channel visibilities in (6.347) and (6.348)) and the SSB channel signatures in Theorem 6.261. Gauge-parameter (ξ) independence of channel observables is ensured by BRST closure; see Proposition 6.276 and the pointwise identities (6.318) and (6.325).

Holosymmetric lift. For any operator/kernel A (e.g. $A \in \pi(\mathcal{A}) \subset \mathrm{End}(\mathcal{H}_{\mathrm{em}})$), define the holosymmetric lift (cf. Proposition 6.257)

$$\mathfrak{H}_{\lambda_{\mathrm{UV}},\ell}[A] \;=\; \sum_{\alpha\in\{\mathrm{corr,vac,spec}\}} \Pi_\alpha\, K_{\mathrm{IR}}^{(\ell)}\, P_x(\lambda_{\mathrm{UV}})\, A\, P_x(\lambda_{\mathrm{UV}})\, K_{\mathrm{IR}}^{(\ell)}\, \Pi_\alpha\,,$$

where the UV/IR tags $P_x(\lambda_{\mathrm{UV}})$ and $K_{\mathrm{IR}}^{(\ell)}$ are given in (6.353), (6.359), and (6.361) (see also Definitions 6.280 and 6.289 and Proposition 6.290). Feeding $\mathfrak{H}_{\lambda_{\mathrm{UV}},\ell}[\cdot]$ into expectation values produces expectation-level observables (cf. the algebra–Hilbert bridge Section 6.1.28 and, e.g., (6.107)); their plateau regularity is controlled by Definition 6.297 and Proposition 6.298.

Properties:

1. *Block-diagonal (no cross-channel couplings).* The sum above is diagonal in the Π_α blocks (see the triadic split (6.306) and the blockwise structure in Proposition 6.257), matching the channelwise diagnostics used for SSB and Berry/WZ phases (cf. Theorem 6.261).
2. *Functorial over direct sums/projections.* The lift respects algebraic decompositions and projections (cf. Proposition 6.257), ensuring compatibility with the construction of expectation-level quantities and with plateau-based stability bounds (Proposition 6.298).
3. *Cone-preserving relative to $\bar{\Sigma}_{\mu\nu}$.* The lift leaves the principal symbol—and thus the chronogeometric light-cone structure—unchanged (cone preservation in Proposition 6.257). For the relational connection and its Levi–Civita form see Definition 6.7 and the Christoffel expression (6.22); related ingredients include Definitions 6.24 and 6.33 and (6.62), (6.74).

Visibilities, RG convention, and Duhamel control.

- **RG scaling convention.** Running couplings at momentum $\mu \sim \ell^{-1}$ obey

$$g_k(\mu) = \mathcal{O}\Big(\mu^{\Delta_k-(d+z)}\Big) \quad (\mu \downarrow 0), \qquad \Longleftrightarrow \qquad g_k(\ell) = \mathcal{O}\Big(\ell^{-(\Delta_k-(d+z))}\Big) \quad (\ell \uparrow \infty),$$

  with the change of variables $\mu = 1/\ell$. On plateau regions $\mathcal{B}$ (cf. Definition 6.297), the scale response of expectation-level fields is uniformly controlled by Proposition 6.298.

- **Channel-restricted visibilities.** Using the projectors $\{\Pi_\alpha\}$ from the holosymmetric framework (cf. Proposition 6.257), define the law- and state-side visibilities (cf. (6.347), (6.348))

$$\Lambda_{\mathrm{law}}^{(\alpha)}(\ell) = \mathrm{Tr}\Big[\Pi_\alpha\, U_B^\dagger(\ell)\, U_A(\ell)\, \Pi_\alpha\, \rho_0\Big],$$
$$\Lambda_{\mathrm{state}}^{(\alpha)}(V) = \Big\langle \Omega_2 \Big|\, \Pi_\alpha\, U^\dagger(V)\, U(V)\, \Pi_\alpha \,\Big|\Omega_1\Big\rangle.$$

  Because the lift is block-diagonal and cone-preserving (see Proposition 6.257), these visibilities inherit channel block-diagonality and preserve the principal chronogeometric cones. Moreover, they are *pointwise* gauge-parameter independent in $\mathcal{H}_{\mathrm{phys}}$ by BRST closure (see Proposition 6.276 and the identities (6.318), (6.325)). As smooth functionals on the IR manifold $\mathcal{M}_{\mathrm{IR}}$, their "defect potentials"

$$\mathcal{V}^{(\alpha)}(\varphi;\ell) := 1 - \Big|\Lambda_{\mathrm{law}}^{(\alpha)}(\ell)\Big|$$

  coincide with the channel visibilities (6.347) and are used to read off asymptotic exponents on plateaus (cf. (6.352), (6.277)).

- **Duhamel/BCH control.** For a scale-dependent perturbation $\delta H(\ell') = \sum_k g_k(\ell')\,\mathcal{O}_k(\ell')$, the channel-projected propagator admits a Duhamel expansion yielding

$$1 - \left|\Lambda^{(\alpha)}_{\mathrm{law}}(\ell)\right| \;\le\; c_{1,\alpha}\int_0^\ell d\ell' \sum_k |g_k(\ell')| \;+\; c_{2,\alpha}\int_{0<\ell''<\ell'<\ell} d\ell'\,d\ell'' \sum_{k,k'} |g_k(\ell')g_{k'}(\ell'')| \;+\; \cdots,$$

  cf. the law-side defect bound (6.311) (see also (6.305), (6.310)). Combining this with the IR scaling laws (6.352) and (6.277) shows that *irrelevant* deformations ($\Delta_k > d+z$) drive a power-law *improvement* of the defects on plateau bands (uniformly controlled by Proposition 6.298):

$$\mathcal{V}^{(\alpha)}(\varphi;\ell) \;=\; \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big) \quad (\ell \uparrow \infty),$$

  in agreement with the IR scaling relations (6.352) and (6.277). Channelwise SSB diagnostics extracted from these visibilities are summarized in Theorem 6.261.

Plateaus (scale stability) and certification.

- **Definition (plateau region).** Let $\mathcal{O}(\lambda_{\mathrm{UV}}, \ell)$ be an observable produced by a scale-tagging functor $\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}$ (cf. the holosymmetric framework in Proposition 6.257 and the expectation-field map (6.362)). Set $u = \ln \lambda_{\mathrm{UV}}$, $v = \ln \ell$, $D_\lambda = \partial_u$, $D_\ell = \partial_v$. On a rectangle $\mathcal{B} = \big[\lambda_{\mathrm{UV},1}, \lambda_{\mathrm{UV},2}\big] \times \big[\ell_1, \ell_2\big]$, we say $\mathcal{O}$ is *plateau* (scale-stable) iff the bounds below hold.

$$\sup_{(u,v)\in \ln \mathcal{B}} \Big|D_\lambda \mathcal{O}\Big| \le \varepsilon_{\lambda_{\mathrm{UV}}}, \qquad \sup_{(u,v)\in \ln \mathcal{B}} \Big|D_\ell \mathcal{O}\Big| \le \varepsilon_\ell.$$

  For expectation-level fields $\mathbf{\Phi}_{\mathrm{IR}}$ (defined via Definition 5.26 together with (6.362)), these bounds imply the finite-difference/stability estimate of Proposition 6.298, which feeds into the visibility functionals (6.302) and their IR improvements (cf. Section 6.12.5, (6.277)).

- **Finite-difference certification.** If $\mathcal{O} \in C^1(\ln \mathcal{B})$ and the plateau criterion holds (cf. Section 6.12.4), then for any two points $(u, v), (u', v') \in \ln \mathcal{B}$,

$$\Big|\mathcal{O}(u', v') - \mathcal{O}(u, v)\Big| \;\le\; \varepsilon_{\lambda_{\mathrm{UV}}}\,|u' - u| \;+\; \varepsilon_\ell\,|v' - v|.$$

  This estimate controls the slow variation of both fields (6.362) and channel-restricted visibilities (6.347)–(6.348) across a plateau, and underlies the extraction of asymptotic exponents entering the scaling relations Section 6.12.5, (6.277).

Gauge-parameter (Nielsen) independence and plateau/exponent invariants.

- **Pointwise ξ-independence (Nielsen invariance).** After inserting the scale tags (and optional Π_α, cf. Proposition 6.257), both law- and state-side visibilities (6.347)–(6.348) are BRST-closed; hence for each fixed scale argument

$$\partial_\xi \Lambda_\square(\cdot) = 0, \qquad \partial_\xi \Lambda^{(\alpha)}_\square(\cdot) = 0.$$

  See Proposition 6.276 and the pointwise identities (6.318), (6.325). This is compatible with cone preservation in Proposition 6.257 and with the relational chronogeometry defined by Definition 6.7 together with (6.22).

- **Plateau locations are gauge-independent.** Because the Nielsen equalities above (see Propositions 6.264 and 6.276 and the pointwise identities (6.294), (6.325)) are *pointwise* in ℓ (or V), predicates such as the plateau criterion Section 6.12.4 and the stability bound Proposition 6.298 hold at the same scale points for all ξ, channel-wise as well. In particular, the IR geodesic transport (with coefficients given by (6.22) from Definition 6.7) is unaffected at principal order by changes of ξ.

- **Asymptotic exponent invariance.** If on a plateau $1 - |\Lambda_{\text{law}}(\ell)| = C\,\ell^{-\beta}\,(1 + r(\ell))$ as $\ell \uparrow \infty$ (cf. the IR scaling relations (6.352) and (6.277)), then the effective exponent

$$\beta_{\text{eff}}(\ell) := -\frac{d\log\Big(1 - |\Lambda_{\text{law}}(\ell)|\Big)}{d\log\ell}$$

  is ξ-invariant. This guarantees that the channelwise SSB diagnostics summarized in Theorem 6.261 are gauge-robust on plateaus.

The SSB arrow. Assuming a G-symmetric, anomaly-free law and a thermodynamic limit, Chapter 6 gives channel-wise SSB signatures:

- **(a) Correlational channel** corr**.** Long-range order/stiffness and gapless Nambu–Goldstone (NG) poles live here; dispersion and soft responses are encoded in $\Lambda_{\text{law}}^{(\text{corr})}(\ell)$ (stable up to irrelevant corrections). If the broken generators are *gauged*, Elitzur/BRST remove the would-be NG poles from $\mathcal{H}_{\text{phys}}$ (quartet mechanism), so no physical NG pole appears in Π_{corr}.

- **(b) Vacuum channel** vac**.** The order parameter is the one-point function in Π_{vac}; distinct SSB vacua become orthogonal in the thermodynamic limit (state-side Π_{vac} visibility tends to 0 with volume V), while on the law side exact G symmetry gives $|\Lambda_{\text{law}}^{(\text{vac})}(\ell)| \to 1$ as $\ell \downarrow 0$.

- **(c) Spectral channel** spec**.** This block isolates commutators/phase curvature. Along adiabatic loops γ in slow-parameter space, the *phase* of $\Lambda_{\text{law}}^{(\text{spec})}$ equals a Berry/Wess–Zumino integral, while the principal symbol—and hence the $\bar{\Sigma}$ light-cones—remain unchanged (only intra-cone phases/subprincipal terms are modified). These geometric terms shift NG couplings/dispersion without altering the cones.

How irrelevant breakings improve law-side visibility. Using the RG convention (cf. (6.352), (6.277)) and the Duhamel bound (cf. (6.311)), *irrelevant* symmetry violations ($\Delta > d + z$) decay as powers of ℓ. Consequently, on plateau regions (cf. Definition 6.297) the law-side visibility defects vanish with exponent $\Delta - (d + z)$ uniformly in scale (cf. the stability bounds Proposition 6.298 and the IR scaling relations (6.352), (6.277)). Explicitly, for the spectral block (and analogously for Π_{vac} and Π_{corr}, using the block-diagonality of Proposition 6.257),

$$\Big|1 - \Lambda_{\text{law}}^{(\text{spec})}(\ell;\varphi,\theta)\Big| \;\le\; C(\varphi,\theta)\sum_{k}\Big|g_k(1/\ell)\Big| \;=\; \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big) \quad (\ell \uparrow \infty),$$

i.e. $\mathcal{O}\big(\ell^{\Delta-(d+z)}\big)$ in the $\ell \downarrow 0$ convention. For the vacuum block one likewise finds $|\Lambda^{(\mathrm{vac})}_{\mathrm{law}}(\ell)| \to 1$ as $\ell \downarrow 0$ (cf. (6.347)), with the same power counting; the associated asymptotic exponents read off from $\mathcal{V}^{(\alpha)}$ are ξ-invariant by Proposition 6.276 (see also (6.318)).

Expectation-level fields and the IR manifold. After lifting by the holosymmetric functor (cf. Proposition 6.257) and coarse-graining, every local operator is mapped to an *expectation-level field*. Concretely, for a multiplet of relational operators $\hat{\mathbf{\Phi}}(x) = \{\hat{\Phi}^a(x)\}_a$ we recall

$$\Phi^a_{\mathrm{IR}}(x;\ell,\lambda_{\mathrm{UV}}) \;:=\; \Big\langle \overset{\circ}{\mathbf{\Psi}}\Big|\, \mathfrak{H}_{\lambda_{\mathrm{UV}},\ell}\Big[\hat{\Phi}^a(x)\Big]\,\Big|\overset{\circ}{\mathbf{\Psi}}\Big\rangle, \qquad a=1,\dots,N,$$

where $|\overset{\circ}{\mathbf{\Psi}}\rangle$ is the GNS cyclic vector (cf. Section 6.1.28). The image of this map defines a smooth *IR configuration manifold*

$$\mathcal{M}_{\mathrm{IR}} \;:=\; \mathrm{Im}\Big(\,\hat{\mathbf{\Phi}} \;\mapsto\; \mathbf{\Phi}_{\mathrm{IR}}(\,\cdot\,;\ell,\lambda_{\mathrm{UV}})\Big)\,,$$

on which slow collective variables φ^i (moduli, order-parameter coordinates, etc.) provide local charts. Plateau regularity is controlled by Proposition 6.298, and the relational chrono-geometry/connection come from Definition 6.7 together with the Christoffel formula (6.22); IR transport is encoded by the geodesics of $\nabla^{(\mathrm{rel})}$. Visibility functionals pull back to smooth IR potentials as in (6.302), with large-ℓ improvement governed by the IR scaling relations Section 6.12.5, (6.277).

Plateau regularity and RG transport. On any plateau block $\mathcal{B}$ (cf. Definition 6.297), the field map (6.354) is scale-stable as stated in Proposition 6.298. Explicitly,

$$\sup_{(u,v)\in \ln\mathcal{B}} \Big\|\partial_v \mathbf{\Phi}_{\mathrm{IR}}(x;\ell,\lambda_{\mathrm{UV}})\Big\| \;\le\; \varepsilon_\ell, \qquad \sup_{(u,v)\in \ln\mathcal{B}} \Big\|\partial_u \mathbf{\Phi}_{\mathrm{IR}}(x;\ell,\lambda_{\mathrm{UV}})\Big\| \;\le\; \varepsilon_{\lambda_{\mathrm{UV}}},$$

with $u = \ln\lambda_{\mathrm{UV}}$, $v = \ln\ell$. In particular, along RG trajectories generated by $\beta^i(\varphi)\partial_{\varphi^i}$ (cf. (6.352)) one has $\dot\varphi^i = \beta^i(\varphi)$ and, on plateaus, $\beta^i(\varphi_\star) \approx 0$, so the φ^i evolve adiabatically. This stability is compatible with the block-diagonal, cone-preserving holosymmetric lift (cf. Proposition 6.257) and underlies the uniform control of the visibility functionals in (6.302) and the scaling relations (6.352), (6.277).

Induced chronogeometry and relational connection. The unified expectation tensor $\bar\Sigma_{\mu\nu}$ induces on $\mathcal{M}_{\mathrm{IR}}$ both a metric and a torsion-free, metric-compatible *relational* connection (see Definition 6.7 and (6.22)):

$$\bar g_{\mu\nu}(x) := \mathsf{P}_{\mathrm{geom}}\Big[\bar\Sigma_{\mu\nu}\Big](\mathbf{\Phi}_{\mathrm{IR}}(x))\,, \qquad \nabla^{(\mathrm{rel})}_\alpha \bar g_{\mu\nu} = 0. \tag{3}$$

Slow configurations $\gamma : s \mapsto \varphi^i(s)$ follow geodesics on $\mathcal{M}_{\mathrm{IR}}$ up to subprincipal corrections, as encoded by the relational Levi–Civita connection Definition 6.7, with Christoffel symbols given explicitly in (6.22):

$$\frac{D^2\varphi^i}{Ds^2} \;+\; \Gamma^i{}_{jk}(\varphi)\,\frac{D\varphi^j}{Ds}\frac{D\varphi^k}{Ds} \;=\; \mathcal{O}\big(\varepsilon_\ell,\varepsilon_{\lambda_{\mathrm{UV}}}\big),$$

where $\Gamma^{i}{}_{jk}$ is the Levi–Civita connection of the moduli-space metric G_{ij} induced, for instance, from connected two-point functions after the holosymmetric lift (cf. Proposition 6.257). By Nielsen/BRST gauge-parameter independence (Proposition 6.276; see also (6.318)), the plateau loci and the exponents extracted from these IR transports are ξ-invariant.

Visibility functionals as IR potentials. Channel-restricted law-side visibilities (Part 2) pull back to smooth functionals on $\mathcal{M}_{\mathrm{IR}}$:

$$\mathcal{V}^{(\alpha)}(\varphi;\ell) \;:=\; 1-\left|\Lambda^{(\alpha)}_{\mathrm{law}}(\ell)\right| \qquad \Big(\text{cf. (6.347)}\Big),$$

and, for irrelevant deformations, satisfy the power-law improvement from Part 6,

$$\mathcal{V}^{(\alpha)}(\varphi;\ell) \;=\; \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big) \quad \text{as } \ell\uparrow\infty, \qquad \text{uniformly on plateaus; cf. (6.352), (6.277).}$$

By Nielsen (gauge-parameter) independence (Part 4; Proposition 6.276), both the plateau loci and the asymptotic exponents extracted from $\mathcal{V}^{(\alpha)}$ are ξ-invariant (see also (6.325)). Along adiabatic loops in slow-parameter space, the spec-channel phase of $\Lambda^{(\mathrm{spec})}_{\mathrm{law}}$ reproduces the Berry/WZ integral without altering the principal cones (Part 5; Theorem 6.261). In summary, $\mathcal{M}_{\mathrm{IR}}$ provides the macroscopic geometric stage on which the diagnostics from Parts 2–6 live: fields (6.362) evolve quasi-geodesically with respect to the relational Levi–Civita connection Definition 6.7 with coefficients (6.22), and the visibility functionals (6.302) obey the plateau/improvement bounds of Proposition 6.298 and the scaling relations (6.352), (6.277).

Algebraic–to–Hilbert-space bridge (GNS) and the concrete operator arena.

- **Representation-independent start.** Begin with the abstract *-algebra $\mathcal{A}$ of operations and relations (no representation chosen). The concrete operator arena used later for visibilities (see (6.347)–(6.348)) and for the holosymmetric lift (see Proposition 6.257) will be obtained functorially from $\mathcal{A}$ via GNS.

- **GNS construction of the "quantum holo-state."** Given a pure state functional $\omega^{\mathring{\mathbf{\Psi}}}: \mathcal{A}\to\mathbb{C}$, the GNS theorem (cf. Section 6.1.28) yields $(\mathcal{H}_{\mathrm{em}}, \pi^{\mathring{\mathbf{\Psi}}}, |\mathring{\mathbf{\Psi}}\rangle)$ with

  $$\omega(A) = \Big\langle \mathring{\mathbf{\Psi}} \,\Big|\, \pi(A) \,\Big|\, \mathring{\mathbf{\Psi}} \Big\rangle, \qquad A\in\mathcal{A}.$$

  Feeding $\pi(A)$ through the holosymmetric lift (cf. Proposition 6.257) and then taking expectations produces the expectation-level fields used on the IR manifold, canonically organized by (6.364) (cf. Definition 6.286).

- **Destination: $\mathrm{End}(\mathcal{H}_{\mathrm{em}})$.** The image $\pi(\mathcal{A})\subset\mathcal{B}(\mathcal{H}_{\mathrm{em}}) =: \mathrm{End}(\mathcal{H}_{\mathrm{em}})$ is the concrete operator arena where the relational observables (e.g. $\hat{\mathbf{\Phi}}(x)$) live. Channel projectors $\{\Pi_\alpha\}$ from the holosymmetric framework act on $\mathcal{H}_{\mathrm{em}}$ to define the channel-restricted visibilities (6.347)–(6.348). Block-diagonality and cone preservation follow from Proposition 6.257 together with the relational connection $\nabla^{(\mathrm{rel})}$ from Definition 6.7 and (6.22); plateau/exponent robustness is ensured by the Nielsen/BRST results Proposition 6.276 (cf. (6.318)).

Emergent chronogeometry and the relational Levi–Civita derivative

- **Chain of emergence.** From the quantum "globe" $\mathcal{X}_q$ and the unified expectation tensor $\bar{\Sigma}_{\mu\nu}$, construct the relational connection $\nabla^{(\mathrm{rel})}_\mu$ (see Definition 6.7); its coefficients are given by (6.22). This is the geometric substrate on which the expectation-level dynamics are read (cf. Definition 6.286, (6.364)) together with the plateau diagnostics Definition 6.297 and Proposition 6.298.

- **Geodesics & effects.** Slow configurations $\gamma : s \mapsto \varphi^i(s)$ evolve along IR geodesics up to subprincipal corrections, governed by the relational Levi–Civita connection Definition 6.7 with symbols (6.22):

$$\frac{D^2\varphi^i}{Ds^2} + \Gamma^i{}_{jk}(\varphi)\,\frac{D\varphi^j}{Ds}\,\frac{D\varphi^k}{Ds} \;=\; \mathcal{O}\big(\varepsilon_\ell, \varepsilon_{\lambda_{\mathrm{UV}}}\big).$$

  Gradients of the temporal tensor $\bar{t}_{\mu\nu}$ (see Definition 6.7 and (6.22)) generate controlled departures from GR-like transport in regimes of strong coherence (e.g. near black-hole or early-universe conditions). The principal cones remain unchanged under adiabatic loops; only intra-cone phases adjust, consistent with the spectral-channel Berry/WZ structure in Theorem 6.261 and the pointwise BRST/Nielsen independence Proposition 6.276 (cf. (6.318)).

Chapter 6 lays the groundwork for dynamics on the emergent chronogeometry by specifying the fundamental field content and the operational structures that govern it. The generalized field doublet $\hat{\mathbf{F}}(x) = (\hat{\mathbf{\Phi}}(x), \hat{\mathbf{\Theta}}(x))^{\mathsf{T}}$ provides the basic degrees of freedom (Definition 6.1), whose correlations are organised by the Unified Inter–Modal Correlator $\hat{\mathbf{G}}_\Lambda(x, x')$ with gauge–covariant transport (Definition 6.4, Section 4.19.1, and eq. (4.11)) [30, 29, 36, 37, 45]. Calculus is performed with the Relational Levi–Civita derivative $\nabla^{(\mathrm{rel})}$, compatible with the composite chronogeometric response $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ (Definition 6.7) [45], and actions are integrated against the state–responsive relational volume element $d\mu = \sqrt{-\det \bar{g}^{\mathrm{Lor}}}\, d^d x$ with $\bar{g}^{\mathrm{Lor}}_{\mu\nu} := \bar{g}_{\mu\nu} + \bar{t}^{\mathrm{sym}}_{\mu\nu}$ (Definition 6.33) [45]. The geometric sector is encoded by an operator–valued Lagrangian density $\mathcal{L}_\Phi$ and its action S_Φ (Definitions 6.172 and 6.174) [36, 37], while the full energy bookkeeping is handled by the Relational Hamiltonian $\hat{H} = \hat{H}_\Phi + \hat{H}_{\Phi\Theta} + \hat{H}_\Theta$ (Definition 6.54 and eq. (6.109)) [30, 29]. Vacua are then identified either variationally via the action or spectrally via $\hat{H}$, yielding the Vacuum Manifold $\mathcal{M}_{\mathrm{vac}}$ that anchors geometric tangents and excitation fibres for subsequent analysis (Section 6.1.17 and Definition 6.61) [30, 29].

Beyond these constructions, the chapter equips the framework with a methodological toolkit for extracting physics. Gauge redundancy is treated cohomologically through BRST quantisation—ensuring nilpotency, gauge–parameter independence, and consistency tests for anomalies (Propositions 6.213, 6.214 and 6.217 and Principles 6.1 and 6.2) [52, 109, 110, 111]. Symmetry organisation is clarified by the duality–quadrant schema, which separates law–level from state–level symmetry via commuting lifts and classifies regimes as Unbroken, SSB, Emergent, or Explicit Breaking (Definitions 6.220, 6.221 and 6.224, Proposition 6.225, Theorem 6.231, and Corollary 6.232) [52, 29]. Operational diagnostics are provided by holosymmetric,

two–path coherence functionals Λ_{law} and Λ_{state}, which are gauge–stable and quadrant–preserving (Definitions 6.237 and 6.238, Lemmas 6.243, 6.247 and 6.248, Proposition 6.251, and Theorem 6.253) [22, 23, 24, 25]. Finally, a scale–aware strategy—UV/IR scale–tagging and the plateau criterion—ensures that claims are robust across reciprocal resolution trade–offs and insensitive to gauge choices (Definitions 6.278, 6.280, 6.282, 6.289, 6.293, 6.295 and 6.297, Propositions 6.294, 6.296, 6.298 and 6.299, and Corollary 6.265) [36, 37, 30, 29].

Chapter 7 Field Laws and Physical States

Physical sector and kernels. Chapter 7 works entirely on the *physical sector*—the BRST cohomology $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$—and at fixed *scale tags* $(\lambda_{\text{UV}}, \ell)$ [52, 112]. It expands the (gauge-fixed) action to quadratic order around a symmetric reference vacuum $(\bar{\Phi}, \bar{\Theta})$ and packages fluctuations as

$$\delta\hat{\mathbf{U}}_{\lambda_{\text{UV}},\ell} := \left(\delta\hat{\mathbf{\Phi}}_{\lambda_{\text{UV}},\ell} \,,\, \delta\hat{\mathbf{\Theta}}_{\lambda_{\text{UV}},\ell} \right)^{\mathsf{T}}.$$

This defines the *gauge-fixed quadratic kernel* $\mathcal{K}_{\Psi}^{(\lambda_{\text{UV}},\ell)}$ and, after projection, the *physical kernel*

$$\mathcal{K}_{\text{phys}}^{(\lambda_{\text{UV}},\ell)} := \mathsf{P}_{\text{phys}}\, \mathcal{K}_{\Psi}^{(\lambda_{\text{UV}},\ell)}\, \mathsf{P}_{\text{phys}},$$

whose inverse (retarded/advanced/Feynman) is the *physical propagator* $\mathcal{D}_{\text{phys}}^{(\lambda_{\text{UV}},\ell)}$ [22] (Definitions 6.274 and 7.15). On $\mathcal{H}_{\text{phys}}$ one has the *cohomological inversion* $\mathcal{K}_{\text{phys}} \cdot \mathcal{D}_{\text{phys}} = \mathbf{1}$, and—crucially—the *pole locations and residues* of $\mathcal{D}_{\text{phys}}$ are *independent of the gauge parameter* (either ξ generically or α_{gf} in the background-field method), since quartet/longitudinal pieces decouple and Slavnov–Taylor/Nielsen identities render gauge-parameter shifts BRST-exact (Proposition 7.16) [112, 38, 109, 113]. For background geometric and measure structures used throughout, see the relational calculus and volume element of Chapter 6 (Definitions 6.7 and 6.33) and the chronogeometric response from Chapters 4–5 (Definition 5.26).

BFM Ward identities and Nielsen control on the band. To control gauge symmetry cleanly, the chapter adopts the *Background-Field Method (BFM)* and imposes background Ward identities together with a *band-limited Nielsen identity* for the 1PI functional Γ [114, 112]. Two key conclusions follow: (i) *pole masses are gauge-parameter independent*; (ii) *on-shell visibilities* are protected. Both hold *on the band*—i.e., after applying the UV projector $P_x(\lambda_{\text{UV}})$ and IR window $K_{\text{IR}}^{(\ell)}$—and remain *robust under admissible regulator changes* within tolerance ε_{reg} [112, 38, 109] (eqs. (7.201), (7.207) and (7.209) and Section 7.3.7). For the UV/IR operators themselves, see the scale-tagging constructions of Chapters 6–7 (Definitions 6.278, 6.280, 6.282 and 6.289).

Band Callan–Symanzik and BRST compatibility. With the *scale-tagged equations of motion* held fixed (eqs. (6.333) and (6.334)), the *Callan–Symanzik equation* holds *on the band* for any renormalised 1PI n-point function $\Gamma_{\text{band}}^{(n)}$, with the usual mass insertions when present [32, 112] (eq. (7.213)). A remark clarifies compatibility with Slavnov–Taylor/Nielsen identities and the band EOM: the UV/IR maps carry ghost number 0, commute with BRST, and thus

preserve the algebraic constraints on visibilities [52, 109]. (For context from Chapter 6: the *scale-tagged EOM* arise by inserting $P_x(\lambda_{\mathrm{UV}})$ and $K_{\mathrm{IR}}^{(\ell)}$ into the operator equations and then projecting to $\mathcal{H}_{\mathrm{phys}}$; their BRST-closedness yields *gauge-parameter invariance in cohomology* at fixed scales, cf. eqs. (6.333) and (6.334) and Definition 6.270.)

UV/IR knobs and plateau certification. The chapter then formalises *scale control* and an *acceptance test* for *plateau stability*. All subsequent constructions are declared to act *on the band* and to be compatible with BRST and the scale-tagged EOM [112] (eqs. (6.333), (6.334) and (6.374)). Three quantitative *plateau metrics*—Slope, Curvature, Oscillation—are defined with a pass criterion: for each audited observable O, the metrics must lie below user-chosen tolerances $\tau_O^{(1)}$, $\tau_O^{(2)}$, $\tau_O^{(\mathrm{osc})}$ throughout a 2D region of $(\lambda_{\mathrm{UV}}, \ell)$. If all audited observables satisfy these bounds, the bandpoint is declared *plateau-stable* and can be used for mode identification and cross-quadrant comparisons (eq. (7.28) and Section 7.3).

Pole extraction and certification workflow. Operationally, *pole extraction* uses *Riesz projectors* on the transverse–traceless kernel $\Gamma^{(\mathrm{TT})}(p^2)$: encircle a (possibly degenerate) pole at $p^2 = -m_i^2$ with a loop γ_i, form

$$\mathbb{P}_i = \frac{1}{2\pi i} \oint_{\gamma_i} \left(\Gamma^{(\mathrm{TT})}(z)\right)^{-1} dz, \qquad \widehat{\Gamma}_i := \mathbb{P}_i \, \Gamma^{(\mathrm{TT})} \, \mathbb{P}_i,$$

and read off m_i^2 from the eigenvalues of $\widehat{\Gamma}_i$ [30]. By the band Nielsen identity, the *pole positions* are α-independent (residues may vary), and the certification step declares *pass/fail* for a bandpoint $(\lambda_{\mathrm{UV}}, \ell)$ by checking algebraic items (C1–C6) together with the plateau metrics [114, 112] (Section 7.3).

Quadrant-wise readings (QI baseline; QIV synopsis). For *Quadrant I* (unbroken laws, symmetric state), mixing respects spin and the BRST projection leaves only *transverse, positive-norm* modes in $\mathcal{H}_{\mathrm{phys}}$ (no ghosts, no tachyons) [52, 112]. QI thus provides a *robust, gauge-independent, scale-stable baseline* against which any sharper particle-level tagging (e.g., "graviton", "Higgs", "apeiron", "chrono-kymon") must be validated on a certified plateau (Sections 7.2.6 and 7.3 to 7.5). For *Quadrant IV* (explicit breaking; asymmetric state), the adjoint-covariant Ward identity on $\mathcal{H}_{\mathrm{phys}}$ acquires a *non-vanishing source* proportional to explicit spurions $\{\epsilon_k\}$ (eq. (7.665)), so Goldstone's theorem does not apply—there are *no exact NG poles* [38]. Instead, would-be NG modes develop *small but nonzero gaps* governed by a *GMOR-type identity*,

$$f_{\pi_b}^2 \, m_{\pi_b}^2 = \sum_k \epsilon_k \left\langle \mathcal{S}_{k,b}^{(\lambda_{\mathrm{UV}})} \right\rangle_{\mathbf{\Psi}} + \mathcal{O}(\epsilon^2),$$

hence $m_{\pi_b}^2 \propto \epsilon$ with vanishing intercept within plateau tolerance [112, 32]. The *splitting pattern* across light multiplets is fixed by the spurion irrep's projection onto broken directions; in practice one isolates a near-degenerate cluster with a Riesz projector, follows its analytic subspace, and uses *Kato parallel transport* for eigenframe labelling [30] (Theorem 7.630, Corollary 7.631, Definitions 7.559 and 7.618, Lemmas 7.566 and 7.619, and Propositions 7.568 and 7.620).

Scale-tagged, BRST-consistent equations on $\mathcal{H}_{\text{phys}}$. Chapter 7 formalises how the *scale-tagged* equations of motion—after UV/IR tagging and channel projection—descend to the physical Hilbert space and become *gauge-parameter independent* via band-limited Nielsen identities on $\mathcal{H}_{\text{phys}}$ [112, 38] (Definition 6.272 and eqs. (6.333), (6.334), (6.374) and (7.201)). Concretely, with the physical projector P_{phys} and BRST differential ζ,

$$\mathsf{P}_{\text{phys}}(\mathcal{E}_\bullet + \zeta\,\chi_\bullet)\,\mathsf{P}_{\text{phys}} = 0,$$
$$\partial_\xi[\mathsf{P}_{\text{phys}}(\mathcal{E}_\bullet + \zeta\,\chi_\bullet)\,\mathsf{P}_{\text{phys}}] = 0.$$

(Similarly, $\partial_{\alpha_{\text{gf}}} = 0$.) See [52, 112]. Here the ζ-exact pieces vanish in BRST cohomology, so the *clean forms* $\mathsf{P}_{\text{phys}}\mathcal{E}_\bullet\mathsf{P}_{\text{phys}} = 0$ hold and are independent of gauge parameters (Nielsen safety on the band; see eq. (7.209) and the discussion following eq. (7.201); cf. also Definition 6.270) [114, 38].

Assuming the UV projector $P_x(\lambda_{\text{UV}})$ and IR window $K_{\text{IR}}^{(\ell)}$ are BRST-closed and commute with the channel projectors $\{\Pi_\alpha\}$, every scale-tagged object produced by the *band functor* $\mathfrak{B}_{\lambda_{\text{UV}},\ell}$ (Definitions 6.278, 6.280, 6.282 and 6.289) *descends* to $\mathcal{H}_{\text{phys}}$, and all channel-resolved observables inherit *gauge-parameter independence* [52, 114, 109, 112]. Symbolically,

$$\mathsf{P}_{\text{phys}}\,\mathfrak{B}_{\lambda_{\text{UV}},\ell}[\cdot]\,\mathsf{P}_{\text{phys}} = \mathfrak{B}_{\lambda_{\text{UV}},\ell}\Big[\mathsf{P}_{\text{phys}}(\cdot)\,\mathsf{P}_{\text{phys}}\Big], \qquad \partial_\xi,\ \partial_{\alpha_{\text{gf}}} \text{ kill physical readouts.}$$

See Definition 6.272 for the precise construction on the band, Definition 6.275 for channel-resolved visibilities on $\mathcal{H}_{\text{phys}}$, and Section 6.12.4 for the plateau criterion that underwrites scale-stable interpretation.

UV/IR knobs, band preparation, and self-adjointness. After restricting dynamics to the physical sector (Stage-I, BRST-consistent regime), the generator $\mathbb{K}(\epsilon)$ preserves $\mathcal{H}_{\text{phys}}$ and remains self-adjoint on a common domain $\mathcal{D}$ [115]. The UV/IR taggers—local spectral projector $P_x(\lambda_{\text{UV}})$ and IR window $K_{\text{IR}}^{(\ell)}$—are chosen so that they commute with $\mathbb{K}(\epsilon)$ and with the channel projectors (the conditions listed in Section 7.3; cf. Definitions 6.278, 6.280, 6.282 and 6.289) [114, 52, 109]. Consequently, the *band-prepared* generator

$$\mathbb{K}^{(x)}(\epsilon) := K_{\text{IR}}^{(\ell)}\,P_x(\lambda_{\text{UV}})\,\mathbb{K}(\epsilon)\,P_x(\lambda_{\text{UV}})\,K_{\text{IR}}^{(\ell)}$$

is again self-adjoint on $\mathcal{D}$ [115, 116]. The *band Hessian* $\mathbb{H}^{(x)}(\epsilon)$—the second variation of the band action around the vacuum—obeys the standard quadratic-form criteria: under the locality/polynomial hypotheses used for the band constructions, the perturbations are form-bounded with relative bound < 1, and by KLMN/Kato–Rellich one obtains a *unique self-adjoint* operator on the same form (hence operator) domain [115, 30] (Section 7.3; see also the preparation of scale-tagged equations in eqs. (6.333), (6.334) and (6.374)).

Plateau geometry in the log-chart and equivalence of definitions. Chapter 7 fixes the parameter-space *log-chart*

$$(u, v) = (\ln\lambda_{\text{UV}}, \ln\ell), \qquad g_{\text{plat}} := du^2 + dv^2, \qquad D_\lambda = \partial_u = \lambda_{\text{UV}}\partial_{\lambda_{\text{UV}}}, \quad D_\ell = \partial_v = \ell\,\partial_\ell,$$

and defines the gradient/Hessian operators used to test plateau stability for C^2 observables [112, 32] (Section 7.3). Two plateau criteria are then shown to be *equivalent (with matched tolerances)*: a channelwise/directional version and a geometric version phrased in terms of gradient smallness and local oscillation bounds on geodesic balls $B_r^{\mathrm{plat}}(\lambda_{\mathrm{UV}}, \ell)$ in the metric g_{plat}. The text proves both inclusions under the stated identification of neighbourhoods and tolerances, establishing operational equivalence of the tests and providing the quantitative thresholds used later for certification (Sections 6.12.4 and 7.3 and eq. (7.28)).

Quadrant logic on a certified plateau $\mathfrak{P}$ Using the *visibilities* $(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}})$ (cf. Definitions 7.35 and 7.42), a *decision rule* $\mathrm{Quad}(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}})$ classifies the plateau into:

QI: $|\Lambda_{\mathrm{law}}| \approx 1$ and $|\Lambda_{\mathrm{state}}| \approx 1$.

QII: law conserved ($|\Lambda_{\mathrm{law}}| \approx 1$), but state decoheres: $\Lambda_{\mathrm{state}}(V) \to 0$ as $V \to \infty$.

QIII: "IR healing" of apparent law deficits: $1 - |\Lambda_{\mathrm{law}}(\ell)| = \mathcal{O}(\ell^{\Delta-(d+z)})$, while $|\Lambda_{\mathrm{state}}| \approx 1$.

QIV: persistent law deficit: $|\Lambda_{\mathrm{law}}| \le 1 - \delta_\star$ on $\mathfrak{P}$ for some $\delta_\star \in (0,1)$, with $\Lambda_{\mathrm{state}}(V) \to 1$.

Here "≈ 1" means $\big||\cdot| - 1\big| \le \varepsilon_{\mathrm{tol}}$ uniformly on $\mathfrak{P}$ in the log-chart variables u, v. This rule makes Ward-type statements and spectral data *readable across scales* on a certified plateau (cf. Section 6.12.4).

Integrated readouts and their inheritance properties. Given channel readouts $R_\alpha(u, v)$, Chapter 8 introduces *integrated readouts* $\overline{R}_\alpha$ (and $\overline{\overline{R}}_\alpha$) obtained by averaging against a weight w supported inside a certified plateau $\mathfrak{P}$ (cf. the plateau definition and certification in Section 6.12.4 and eq. (7.28)). On a certified plateau, the *same* gradient/curvature/oscillation bounds *carry over* to the integrated objects—with equal or better constants:

$$\big|\partial_v \overline{R}_\alpha\big| \le \varepsilon_{\mathrm{grad}}, \qquad \big\|\nabla^2 \overline{R}_\alpha\big\| \le \varepsilon_{\mathrm{curv}}, \qquad \mathrm{osc}\,[\overline{R}_\alpha] \le \varepsilon_{\mathrm{osc}},$$

and analogously in u. Discrete counterparts follow by replacing integrals with convex combinations (see eqs. (7.413) and (7.414)).
The *integrated vs. pointwise diagnostic* at a reference point $(u_*, v_*) \in \mathrm{supp}(w)$,

$$\Delta_\alpha := \big|\overline{R}_\alpha - R_\alpha(u_*, v_*)\big|,$$

is $\mathcal{O}(\varepsilon_{\mathrm{plat}})$ by the inheritance lemma together with a mean-value estimate *within* $\mathfrak{P}$; reports should include Δ_α and the weight's shape/support (cf. eq. (7.390)).

Discrete IR window and curvature-based plateau test (error control). For a grid v_k with mesh h and a smoothed curvature proxy $\phi_h = \mathsf{LP}_{\tau,h}\,\mathsf{D}_2 f$, one has the uniform second-order *consistency*

$$\phi_h(k) = \phi(v_k) + \mathcal{O}(h^2), \qquad \sup_k \big|\phi_h(k) - f''(v_k)\big| = \mathcal{O}(h^2) + \mathcal{O}(\tau^2),$$

using the bias expansion with an even kernel W of finite $m_2(W)$. Defining the continuous IR window $\mathcal{I}_{\mathrm{IR}} = \{\, v : \ |\phi(v)| \le \varepsilon_{\mathrm{curv}} \,\}$ and its *grid* counterpart $\mathcal{I}_{\mathrm{IR}}^{(h)} = \{\, k : \ |\phi_h(k)| \le \varepsilon_{\mathrm{curv}} \,\}$, the chapter proves a *band-measure control*

$$\mu\Big(\mathcal{I}_{\mathrm{IR}} \,\triangle\, \mathcal{I}_{\mathrm{IR}}^{(h)}\Big) \le C\,\delta_\phi = \mathcal{O}(h^2),$$

under Lipschitz regularity of ϕ on the operational window (cf. Proposition 7.397).

Ward-operator bounds and Nielsen projection. Expanding the *Ward operator* around the symmetric point and evaluating on-shell yields a linear-response representation with *band-limited kernels* $\mathcal{K}_A^a(p;\ell)$. Taking operator norms on the compact band $\mathfrak{B}(\lambda_{\mathrm{UV}},\ell)$ gives a uniform bound

$$\mathcal{W}(\ell) \ \le \ C(\lambda_{\mathrm{UV}},\ell)\sum_A \Big|\varepsilon_A(\kappa/\ell)\Big| + \mathcal{O}(\|\varepsilon\|^2),$$

where $C = \sum_A C_A$ encodes band suprema of the kernel/reference-operator ratio. Passing to *Nielsen-projected eigen-couplings*—a change of basis R that Jordanises the projected stability matrix on $W = \mathrm{im}\,\mathcal{N}$—improves interpretation and stabilises the flow (cf. Definitions 7.454 and 7.457).

Joint (multi-channel) integrated plateaus. For a set of channels $\mathfrak{C} \subset \{\mathrm{law}, \mathrm{state}, \mathrm{mix}, \ldots\}$ and averaging widths $(\Delta\lambda, \Delta\ell)$ (or $(\Delta u, \Delta v)$), the *joint integrated plateau* is

$$\overline{\mathfrak{P}}_{\mathfrak{C}}(\Delta\lambda,\Delta\ell) := \bigcap_{\alpha\in\mathfrak{C}} \Big\{ (\lambda_{\mathrm{UV}},\ell) \in \mathcal{R} : \ \overline{\Lambda}_\alpha \text{ satisfies Section 7.3.5 with prescribed tolerances} \Big\},$$

with inheritance-consistent tolerances per α. It *includes* the pointwise joint plateau when the averaging box stays inside the test ball and tolerances match; conversely, under a $C^{1,1}$ assumption on each channel and small enough half-sizes $\Delta u/2, \Delta v/2 \le r$, one gets *reverse inclusion* after *rescaling* tolerances using channel Lipschitz data (cf. eq. (7.64)).

Operational process.

1. *Prepare the band* with BRST-closed taggers $P_x(\lambda_{\mathrm{UV}})$, $K_{\mathrm{IR}}^{(\ell)}$; restrict to $\mathcal{H}_{\mathrm{phys}}$; ensure self-adjoint $\mathbb{K}^{(x)}$ and $\mathbb{H}^{(x)}$. (cf. Section 7.1.4 and Definition 6.282)

2. *Certify a plateau* in the log-chart by gradient, curvature, oscillation tolerances on B_r^{plat}; use the geometric/channelwise equivalence to choose the most convenient test. (cf. Definition 7.47 and Section 6.12.4)

3. *Classify the physics* on $\mathfrak{P}$ via $\mathrm{Quad}(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}})$ (QI–QIV) to read Ward statements and spectra consistently across scales. (cf. Definition 7.685)

4. *Report integrated readouts* $\overline{R}_\alpha$; include the *diagnostic gap* Δ_α and the averaging weight/-support, knowing the plateau tolerances inherit. (cf. Lemma 7.345 and eq. (7.418))

5. *Discrete implementation*: use the curvature-window method; budget $\mathcal{O}(h^2)$ (mesh) and $\mathcal{O}(\tau^2)$ (smoothing) errors; control the symmetric-difference measure of the IR window. (cf. Propositions 7.382 and 7.397)

6. *Linear response*: bound $\mathcal{W}(\ell)$ by band-kernels times small couplings; optionally *Nielsen-project* to eigen-couplings for sharper flow control. (cf. Definition 7.454)

Quadrant Analysis Strategy. Chapter 7 outlines a systematic, scale-aware strategy (Section 6.12.5) using the variational backbone (Section 6.12.2) and operational diagnostics (Section 6.12.3) to analyze each quadrant. All analyses are performed within the physical sector $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$ (Remark 6.226), ensuring gauge invariance and relying on plateau stability (Section 6.12.4) for robust results. Mode identifications (like "Higgs-like", "graviton-like") remain provisional until confirmed stable on a plateau (Definition 6.300).

QI (law symmetric, state symmetric) Goal (baseline). On a certified plateau $\mathfrak{P}$, QI is the fully coherent reference case: both visibilities satisfy $\left|\Lambda_{\text{law}}\right| \approx 1$ and $\left|\Lambda_{\text{state}}\right| \approx 1$ (tolerance semantics on $\mathfrak{P}$ in the $(u, v) = (\ln \lambda_{\text{UV}}, \ln \ell)$ chart); this is the calibration baseline for all other quadrants, as fixed by the canonical decision rule Definition 7.685 and Remark 7.686. (Log-chart/plateau geometry used throughout is defined in Definition 7.47 and Section 6.12.4.)

Checks

- *Scale-tagged physical EOMs (clean, gauge-independent).* On $\mathcal{H}_{\text{phys}}$ the BRST-exact pieces drop out and the "clean forms" hold,

$$\mathsf{P}_{\text{phys}}\big(\mathcal{E}_\bullet + \zeta\, \chi_\bullet\big)\, \mathsf{P}_{\text{phys}} = 0, \qquad \partial_\xi(\cdot) = 0 \quad \text{(Nielsen safety)},$$

  so the physical equations are independent of gauge parameters/presentation choices on certified plateaus; see Section 7.1.3 (with inputs from Definition 6.272). Moreover the BRST-closed UV/IR taggers commute with channel projections, and the band functor descends:

$$\mathsf{P}_{\text{phys}}\ \mathfrak{B}_{\lambda_{\text{UV}},\ell}[\cdot]\ \mathsf{P}_{\text{phys}} = \mathfrak{B}_{\lambda_{\text{UV}},\ell}\Big[\mathsf{P}_{\text{phys}}(\cdot)\,\mathsf{P}_{\text{phys}}\Big],$$

  ensuring all scale-tagged objects/readouts are defined on $\mathcal{H}_{\text{phys}}$ (and remain gauge-independent); cf. Section 7.1.4 and Definition 6.282.

- *Ward/Slavnov–Taylor conservation in $\mathcal{H}_{\text{phys}}$.* The scale-tagged Ward identity on the physical sector reads, schematically,

$$\nabla_\mu^{(\text{ad})}\, \bar{J}^\mu_{a,\text{imp}} = \sum_k \epsilon_k\, \mathcal{S}^{(\lambda_{\text{UV}},\ell)}_{a,k} \quad \text{on } \mathcal{H}_{\text{phys}},$$

  with all right-hand terms BRST/Nielsen-safe. In QI (no explicit breaking in the law channel), $\epsilon_k = 0$ and conservation is exact: $\nabla_\mu^{(\text{ad})} \bar{J}^\mu_{a,\text{imp}} = 0$. Definition 7.567 and eq. (7.665).

- *Spectrum health from the physical Hessian.* Linearisation about the symmetric vacuum gives the physical Hessian $\mathbb{H}^{(\lambda_{\text{UV}},\ell)}_{\text{phys}}$ via the linearised Euler–Lagrange system eq. (6.332) (and, in the band-prepared setting, eq. (7.10)). On $\mathcal{H}_{\text{phys}}$ the two-point functions admit a Källén–Lehmann representation with positive weights; poles/residues are gauge-parameter independent, giving positivity (no ghosts) and a non-tachyonic spectrum under the stated hypotheses. eqs. (7.12), (7.14) and (7.15) and Corollary 7.24.

- *Holosymmetric visibilities at unity on* $\mathfrak{P}$. The (holosymmetric) visibilities are BRST/Nielsen-safe and normalised so that on QI plateaus they satisfy

$$\left|\Lambda_{\text{law}}(\ell)\right| \approx 1 \quad \text{and} \quad \left|\Lambda_{\text{state}}(V)\right| \approx 1.$$

  Definitions 6.275 and 7.685.

In Chapter 7 the Law-State quadrant means: clean, gauge-independent physical equations; exact Ward conservation on $\mathcal{H}_{\text{phys}}$; a positive, ghost-free, non-tachyonic spectrum from the physical Hessian; and visibilities pinned to unity on a certified plateau—precisely as encoded by the canonical quadrant rule.

QII (law symmetric, state asymmetric) Goal (broken phase, conserved law). On a certified plateau $\mathfrak{P}$, QII keeps *law*-level conservation intact while the *state* decoheres because a vacuum manifold is present. In the canonical decision rule this is recorded as $\left|\Lambda_{\text{law}}\right| \approx 1$ and $\Lambda_{\text{state}}(V) \to 0$ as $V \to \infty$; the remark explicitly ties the decoherence to the manifold of vacua that become orthogonal at large volume (cf. Definition 7.685 and Remark 7.686).

Vacuum structure and unbroken subgroup. The broken-phase bookkeeping is given in terms of the decomposition of the Lie algebra into unbroken versus broken pieces, with the counts

$$r_{\text{g}} = \dim \mathfrak{g}_{\text{gauge}} - \dim \mathfrak{h}_{\text{gauge}}, \qquad r_{\text{gl}} = r - r_{\text{g}},$$

and all statements to be evaluated on $\mathcal{H}_{\text{phys}}$ and certified plateaus. This encodes the unbroken subgroup (here, $\mathfrak{h}_{\text{gauge}}$ on the gauged side) and sets the stage for mode counting around any chosen vacuum on the manifold (cf. Definition 6.61).

Hessian analysis and mode content (Goldstone vs. BEH). Linearising about a symmetry-broken vacuum and reading the *band* Hessian on the physical sector gives the expected spectrum:

- unbroken gauged generators $\mathfrak{h}_{\text{gauge}}$: massless spin-1 vectors (physical polarisations after BRST projection);
- broken *global* generators: r_{gl} Nambu–Goldstone scalars (gapless in the $V \to \infty$ limit, with standard caveats for nonrelativistic/type-B cases);
- broken *gauged* generators: r_{g} massive vectors via Brout–Englert–Higgs reorganisation; the would-be NG modes are "eaten" and are not separate physical excitations.

All counts and readings are taken in $\mathcal{H}_{\text{phys}}$ on certified plateaus (cf. eq. (7.10) and Propositions 6.213 and 7.22).

Law channel (conservation) and quartet decoupling. In the band/IR-tagged setting the improved currents obey the scale-tagged Ward structure; with no explicit breakers in QII, law-level conservation survives on $\mathcal{H}_{\text{phys}}$. Ghosts, antighosts, Nakanishi–Lautrup fields and longitudinal gauge modes organise into Kugo–Ojima quartets and decouple, so physical poles come from the transverse blocks of the Hessian (cf. Definition 7.567, eq. (7.665), and Proposition 7.22).

State channel (preparation and ordered limits). The broken state is prepared by a seed that *does not* alter the symmetric operator content used by the law-channel meters; ordered

limits $\varepsilon \to 0^+$, then $V \to \infty$, then the plateau scan, produce distinct symmetry-broken branches that become orthogonal as $V \to \infty$. This realises $\Lambda_{\text{state}}(V) \to 0$ while keeping $\left|\Lambda_{\text{law}}\right| \approx 1$ (cf. Remark 7.686 and Definition 6.275).

Gauge/Nielsen safety and plateau robustness. With BRST-closed UV/IR tags, the dynamics descends to $\mathcal{H}_{\text{phys}}$ and physical spectra/matrix elements are gauge-parameter independent (Nielsen identities). Within the IR window used for audits, pole positions and residues have $\partial_\xi m_\alpha^2 = \partial_\xi Z_\alpha = 0$ (within tolerance). Plateau acceptance criteria (slope/curvature/oscillation budgets) gate the analysis (cf. Sections 6.12.4 and 7.1.3 and Definitions 6.272, 6.282 and 7.47).

Net QII signature (Chapter 8). On $\mathfrak{P}$: exact law conservation and ghost/longitudinal decoupling (law visibility at unity), a vacuum manifold that drives state-sector decoherence as $V \to \infty$ (state visibility to zero), and a spectrum with NG modes for broken global symmetries and BEH-massive vectors for broken gauged ones—each read in the band-prepared, BRST-physical sector with gauge-independent pole data (cf. Definitions 6.275 and 7.685).

QIII (law asymmetric, state symmetric): what Chapter 8 establishes. Goal (emergent symmetry). QIII captures cases where explicit microscopic breaking is present but *irrelevant* in the renormalisation–group sense, so the *law channel heals in the IR* while the *state channel remains symmetric* on a certified plateau $\mathfrak{P}$. In the canonical decision rule this reads

$$1 - \left|\Lambda_{\text{law}}(\ell)\right| \xrightarrow[\ell\to\infty]{} 0, \qquad \left|\Lambda_{\text{state}}(V)\right| \approx 1 \quad \text{(tolerance semantics on } \mathfrak{P}\text{)},$$

classifying the law as asymptotically exact while the state shows no SSB (cf. Definitions 6.275 and 7.685 and Section 6.12.4).

Checks (with operative scalings and plateau controls).

1. **Setup with irrelevant explicit breakers.** Work with a scale–tagged Lagrangian that includes explicit symmetry–breaking insertions

$$\sum_k \varepsilon_k \mathcal{O}_k, \qquad \Delta_k > d + z,$$

so each $\mathcal{O}_k$ is RG–irrelevant. The "relational Ward'' control sets the decay rate in the IR by the leading irrelevant dimension $\Delta := \min_k \Delta_k$ (cf. Lemma 6.233 and Definition 7.567).

2. **Ward–identity violation decays at a power law.** On the physical sector $\mathcal{H}_{\text{phys}}$, the scale–tagged Ward deviation $\Delta_a^{(\lambda_{\text{UV}},\ell)}$ obeys the IR law

$$\Delta_a^{(\lambda_{\text{UV}},\ell)} = \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big) \quad (\ell \to \infty),$$

equivalently $\mathcal{O}\Big(\mu^{\Delta-(d+z)}\Big)$ for $\mu \sim 1/\ell$ (cf. eq. (6.377) and Lemma 6.233).

3. **Law–coherence deficit heals with the same exponent.** The visibility deficit tracks the Ward decay:

$$1 - \left|\Lambda_{\text{law}}(\ell)\right| = \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big),$$

so the law channel tends to unity on $\mathfrak{P}$ (cf. Proposition 6.277 and Definition 7.685).

4. **State remains symmetric.** Within the certified IR window, order parameters vanish and the state visibility stays at unity (within tolerances):

$$\left|\Lambda_{\text{state}}(V)\right| \approx 1 \quad \text{on } \mathfrak{P},$$

with inheritance to integrated readouts $\overline{R}_\alpha$ (cf. Definition 6.275, Lemma 7.345, and eq. (7.390)).

5. **Plateau certification and discrete IR–window test.** Use the chapter's log–chart $u = \ln \lambda_{\text{UV}}$, $v = \ln \ell$ and metric g_{plat} to enforce gradient/curvature/oscillation tolerances (cf. Definition 7.47 and Section 6.12.4). For implementations on a grid v_k with mesh h, the smoothed curvature proxy $\phi_h = \mathsf{LP}_{\tau,h}\,\mathsf{D}_2 f$ satisfies

$$\phi_h(k) = \phi(v_k) + \mathcal{O}(h^2), \qquad \sup_k \left|\phi_h(k) - f''(v_k)\right| = \mathcal{O}(h^2) + \mathcal{O}(\tau^2),$$

and the symmetric–difference measure between the continuous and grid IR windows is controlled by

$$\mu\Big(\mathcal{I}_{\text{IR}} \,\triangle\, \mathcal{I}_{\text{IR}}^{(h)}\Big) = \mathcal{O}(h^2),$$

which underwrites robust QIII diagnoses on $\mathfrak{P}$ (cf. Propositions 7.382 and 7.397).

6. **Gauge/Nielsen safety.** Because the UV/IR taggers are BRST–closed and commute with channel projectors, all band–limited objects descend to $\mathcal{H}_{\text{phys}}$, and physical readouts are gauge–parameter independent:

$$\partial_\xi(\text{physical readout}) = 0, \quad \partial_{\alpha_{\text{gf}}}(\text{physical readout}) = 0,$$

within the plateau tolerances (cf. Section 7.1.3 and Definition 6.282).

Net QIII signature On a certified plateau $\mathfrak{P}$: (i) explicit breaking is present but irrelevant; (ii) the Ward deficit and the law–visibility deficit both decay as $\ell^{-(\Delta-(d+z))}$; (iii) the state channel remains symmetric, $\left|\Lambda_{\text{state}}\right| \approx 1$; (iv) all statements are BRST-/Nielsen–safe and stable under the chapter's plateau certification and discrete IR–window controls (cf. eq. (6.377), Propositions 6.277, 7.382 and 7.397, Definitions 6.275 and 7.47, and Section 7.1.3).

Quadrant IV vs. III — resolving the mismatch. Quadrant IV describes *persistent explicit breaking* driven by relevant/marginal spurions $\{\epsilon_k\}$, together with a *non-vanishing Ward deficit in the IR* and *state coherence* in a unique (non-symmetric) vacuum. In Chapter 7 this appears as an adjoint–covariant Ward identity with a source term proportional to the spurions (eq. (7.665)) and leads to GMOR–type gaps for the would-be NG modes, $f_{\pi_b}^2 m_{\pi_b}^2 = \sum_k \epsilon_k \langle \mathcal{S}_{k,b}^{(\lambda_{\text{UV}})} \rangle_{\mathbf{\Psi}} + \mathcal{O}(\epsilon^2)$, hence $m_{\pi_b}^2 \propto \epsilon$ within plateau tolerance (Theorem 7.630 and Corollary 7.631). The *assignment and covariance* of spurions, and the extraction of near-degenerate multiplets via Riesz projectors with Kato parallel transport, are spelled out in Definitions 7.559 and 7.618, Propositions 7.568 and 7.620, and Lemma 7.619. In Chapter 8 this constellation is the signature of *QIV* (persistent law deficit with a coherent state), not QIII.

By contrast, Quadrant III is the *emergent-symmetry* case: the explicit breaking is RG-irrelevant and the *law channel heals in the IR* while the state remains symmetric. Band diagnostics formalise this healing via IR-window invariance and stability of curvature-based tests (Proposition 7.397), consistent with the band Callan–Symanzik control (eq. (7.213)) and with gauge-parameter–independent visibilities (Nielsen safety on the band; eq. (7.209)). For interpreting flows, the chapter also uses the *Nielsen projection* and an eigen-basis that Jordanises the projected stability matrix, improving channelwise readings in the law sector (Definitions 7.454 and 7.457).

QIV (law asymmetric, state coherent). Goal (explicit breaking that persists at all scales). Work on a scale–tagged band that lies on a certified plateau $\mathfrak{P}$ (Definitions 7.31 and 7.96 and eq. (7.28)) produced by the band functor with UV/IR taggers (Definitions 7.26, 7.27 and 7.29). Introduce explicit symmetry–breaking spurions in the Lagrangian,

$$\mathcal{L} = \mathcal{L}_{\text{sym}} + \sum_k \varepsilon_k \mathcal{O}_k, \qquad \Delta_k \le d + z, \quad \varepsilon_k \neq 0,$$

so the breaking is relevant/marginal and does *not* wash out in the IR—the defining setting of the QIV sector (Section 7.9 and Theorem 7.557).

Checks (operational).

1. **Ward channel: non-vanishing IR violation.** The scale-tagged *physical* Ward identity on $\mathcal{H}_{\text{phys}}$ carries a persistent adjoint–covariant source proportional to the spurions ($\{\varepsilon_k\}$) and does *not* heal in the IR (Definition 7.567, eq. (7.147), and Theorem 7.570). In visibility language, the *law* channel is uniformly below unity on $\mathfrak{P}$:

$$\left|\Lambda_{\text{law}}(\ell)\right| \le 1 - \delta_\star.$$

   Here $\delta_\star \in (0,1)$ is uniform on the certified plateau $\mathfrak{P}$ (see Definition 7.553, Theorem 7.580, and Corollary 7.677).

2. **Spectrum and pseudo–Nambu–Goldstones (pNG).** Diagonalising the *physical*, band-prepared Hessian $\mathbb{H}^{(\lambda_{\text{UV}},\ell)}$ yields *pNG* modes when a symmetry is explicitly (but weakly) broken (eq. (7.10) and Proposition 7.629). Their masses obey GMOR-type relations controlled by spurion insertions and symmetry-breaking densities on $\mathcal{H}_{\text{phys}}$ (Section 7.9.11, Theorem 7.630, Corollary 7.631, and Proposition 7.627).

3. **State channel: coherence, not a vacuum cat.** Explicit breaking selects a *unique* non-symmetric vacuum, so the state-sector visibility remains near unity on large volumes,

$$\left|\Lambda_{\text{state}}(V)\right| \approx 1 \quad (V \to \infty),$$

   i.e. no macroscopic decoherence over a vacuum manifold (Definition 7.103 and Section 7.9.6). Contrast this with QII, where $\Lambda_{\text{state}}(V) \to 0$ as $V \to \infty$ due to SSB over a vacuum manifold (Sections 7.7 and 7.7.4).

4. **BRST/Nielsen safety and plateau robustness.** BRST-closed UV/IR taggers and commuting channel projectors ensure descent to $\mathcal{H}_{\text{phys}}$ and *gauge-parameter independence* of readouts (Nielsen safety on the band) (Definition 7.671, Propositions 7.130 and 7.236, and eq. (7.209)). Acceptance on $\mathfrak{P}$ is gated by the chapter's plateau criteria—small slope/curvature/oscillation in the log-chart $(u, v) = (\ln \lambda_{\text{UV}}, \ln \ell)$ (Definitions 7.47 and 7.96 and eq. (7.28)), and discrete IR-window controls make the tests numerically robust (Proposition 7.397 and Corollary 7.417).

Net QIV signature. In Quadrant IV the breaking terms are *explicit* and *relevant/marginal* ($\Delta_k \leq d + z$), so they do not wash out under the UV/IR flow on the band [32, 112]. Operationally, the adjoint–covariant, scale–tagged *physical* Ward identity carries a persistent IR source (no healing), cf. eq. (7.665); equivalently, the *law visibility* defined on $\mathcal{H}_{\text{phys}}$ satisfies $|\Lambda_{\text{law}}| < 1$ uniformly across the certified plateau $\mathfrak{P}$ [114, 38] (Definition 6.275, Section 6.12.4, and eq. (7.28)). By contrast, the *state visibility* remains near unity because explicit breaking selects a unique (non–symmetric) vacuum, so $|\Lambda_{\text{state}}| \approx 1$ on large volumes (no decoherence across a vacuum manifold) [112, 32]. All statements are made on the BRST–physical sector with band–limited operators—UV projector $P_x(\lambda_{\text{UV}})$ and IR window $K_{\text{IR}}^{(\ell)}$ that commute with channel projectors—and are *Nielsen–safe* by the band Nielsen identities [52, 114, 38, 112] (Definitions 6.272, 6.278, 6.280, 6.282 and 6.289 and eqs. (7.201) and (7.209)). Spectrally, would–be NG modes acquire small gaps governed by *GMOR–type* relations [112, 32] (Theorem 7.630 and Corollary 7.631).

One–line contrast with QIII (for orientation). Quadrant III realises *emergent symmetry*: explicit breakers are RG–*irrelevant* ($\Delta_k > d+z$), the Ward deficit and the law–visibility deficit *decay* in the IR with the predicted power law, and the state remains symmetric [32, 112] (cf. Proposition 7.397 and eqs. (7.209) and (7.213)). Quadrant IV has *relevant/marginal* breakers; the Ward deficit *persists* (no decay) while the state remains *coherent* due to a unique vacuum [114, 38] (eq. (7.665) and Theorem 7.630).

Classification on certified plateaus. On a certified plateau $\mathfrak{P}$ in the log–chart $(u, v) = (\ln \lambda_{\text{UV}}, \ln \ell)$ (Definition 7.47 and Section 6.12.4), Chapter 7 uses a canonical decision rule based on the *witness pair* $(\Lambda_{\text{law}}, \Lambda_{\text{state}})$ to assign quadrants [114, 52, 112] (Definitions 6.275 and 7.685). The law channel tests whether Ward/Slavnov–Taylor constraints are effectively exact on $\mathfrak{P}$ [38]; the state channel tests whether macroscopic preparation decoheres across a vacuum manifold [112]. Because the UV/IR taggers are BRST–closed and the equations are projected to $\mathcal{H}_{\text{phys}}$, all readouts are *Nielsen–safe* (gauge–parameter independent) [114, 52, 38, 112], and the plateau criteria—small gradient/curvature/oscillation—ensure stability of the verdicts (Definitions 6.272, 6.278, 6.280 and 6.289 and eqs. (7.28) and (7.201)).

QI (law symmetric, state symmetric). This is the calibration baseline: $|\Lambda_{\text{law}}| \approx 1$ and $|\Lambda_{\text{state}}| \approx 1$ on $\mathfrak{P}$. Scale–tagged equations reduce to clean, gauge–independent forms on $\mathcal{H}_{\text{phys}}$ [114, 38, 112] (Definition 6.272 and eqs. (6.333) and (6.334)); Ward identities are exactly conserved; and the physical (band–prepared) Hessian yields a positive, ghost–free, non–tachy-

onic spectrum with gauge–independent pole data [52, 114, 38, 30] (see $\mathcal{K}_{\rm phys}$–inversion and band Nielsen control in Proposition 7.16 and eq. (7.209); cf. Section 7.2.6).

QII (law symmetric, state asymmetric). The law channel remains at unity, but the state decoheres as volume grows because a vacuum manifold is present: $\Lambda_{\rm state}(V)\to 0$ as $V\to\infty$ while $|\Lambda_{\rm law}|\approx 1$ [32, 112] (Definition 6.275). Around a chosen vacuum, NG modes appear for broken *global* generators; for broken *gauged* generators the would–be NG modes are BRST–exact (eaten) and vectors become massive (BEH), all read on $\mathcal{H}_{\rm phys}$ with quartet decoupling ensuring that only transverse/matter poles are physical [38, 52, 109] (Section 7.2.6 and eq. (7.209)).

QIII vs. QIV (law asymmetric, state symmetric/coherent). In **QIII** the microscopic breaking is RG–irrelevant and the law channel *heals* in the IR with the predicted power law $1-|\Lambda_{\rm law}(\ell)| = \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big)$ (band CS control) [32, 112] (eq. (7.213) and Proposition 7.397), while the state remains symmetric $|\Lambda_{\rm state}|\approx 1$. In **QIV**, relevant/marginal explicit breakers keep a *persistent* law deficit: $|\Lambda_{\rm law}(\ell)|\le 1-\delta_\star$ on $\mathfrak{P}$, yet the state is coherent $|\Lambda_{\rm state}|\approx 1$ because a unique non–symmetric vacuum is selected; pseudo–NG masses track the breaking scales (GMOR–type relations) [112, 32] (Theorem 7.630 and Corollary 7.631). Across all quadrants, plateau certification and the discrete IR–window controls secure numerical robustness, and BRST/Nielsen safety guarantees that quadrant assignment is invariant under admissible gauge choices and band preparation [114, 38, 112] (Section 6.12.4, eqs. (7.28) and (7.209), and Proposition 7.397).

Intuition. "The law heals in the IR" signals that any apparent violation of dynamical constraints—those encoded by Ward/Slavnov–Taylor relations and their Nielsen-controlled refinements—diminishes under coarse–graining. At sufficiently long wavelengths, the effective description recovers the symmetry relations to the accuracy set by the infrared scale, so the constraints become effectively exact again [114, 38, 112].

Scaling statement. Let the law visibility be $\Lambda_{\rm law}(\ell)$ and define the law deficit $\delta_{\rm law}(\ell) := 1-|\Lambda_{\rm law}(\ell)|$. In Quadrant III, where the explicit breaking operators are RG–irrelevant ($\Delta>(d+z)$), the deficit obeys the band Callan–Symanzik control

$$\delta_{\rm law}(\ell) \;=\; \mathcal{O}\Big(\ell^{-(\Delta-(d+z))}\Big), \qquad \Delta>(d+z),$$

so the deficit decays as the IR window ℓ grows [32, 112] (eq. (7.213)).

Band preparation on $\mathcal{H}_{\rm phys}$. After UV/IR tagging and projection to the physical Hilbert space, the band–prepared Ward identities exhibit a vanishing IR source, and the clean forms of the scale–tagged equations hold to increasing precision [114, 38] (Definition 6.272 and eqs. (6.333) and (6.334)). This is the operational content of "healing": the cohomological projection removes unphysical components so that only the symmetry–respecting content survives on $\mathcal{H}_{\rm phys}$ [52].

Nielsen safety. Because all statements are formulated on $\mathcal{H}_{\text{phys}}$ with band–limited operators, the band Nielsen identities enforce gauge–parameter independence of the recovered relations; the healing is therefore a property of the physics, not of the gauge choice [114, 38, 112] (eqs. (7.201) and (7.209)).

Plateau robustness. On a certified plateau $\mathfrak{P}$ in the log–chart, the diagnostics (SLOPE, CURVATURE, OSCILLATION) sit below the prescribed tolerances across a two–dimensional region, so the limit $|\Lambda_{\text{law}}| \to 1$ is numerically stable and operationally meaningful for mode identification and comparisons [112] (Sections 6.12.4 and 7.3 and eq. (7.28)).

Chapter 8: Parasymmetric Witnesses and Diagnostics

What Chapter 8 does (methods, band, and witnesses). Chapter 8 is a *methods* chapter: it locks all calculations to the *band* (fixed UV/IR tags) and to the *physical BRST cohomology*, then builds *witnesses*—numerical visibilities in $[0, 1]$—that answer, channel by channel, "are the *laws* effectively symmetric here?" and "is the *state* coherently symmetric here?" [114, 52, 112] (cf. Definitions 6.272, 6.275, 6.278, 6.280 and 6.282). The machinery that makes those answers trustworthy is: (i) *Nielsen safety* (gauge–parameter independence on shell) [114, 38, 112] (eqs. (7.201) and (7.209) and Proposition 7.208), (ii) *cohomological inversion* (ghost/longitudinal pieces decouple before propagator inversion) [117, 52] (Proposition 7.16 and Definition 6.274), (iii) *Riesz projectors* to extract pole locations (gauge–independent) [115, 30] (eq. (7.438) and Definition 7.286), and (iv) *plateau certification* in a log–scale geometry (small slope/curvature/oscillation), with integrated–readout and discrete–IR controls [32, 112] (Section 6.12.4, eq. (7.28), and Propositions 7.146 and 7.397). With those in hand, a *canonical decision rule* assigns each certified bandpoint to one of four quadrants (QI–QIV), cleanly separating unbroken, SSB, emergent, and explicit–breaking regimes (Definition 7.685).

Synthesis, sectors, and extensions. The second big idea is *synthesis and extensibility*. The same witness logic is made *sector–conditioned* (TT vs. longitudinal, spin/charge, boundary vs. bulk; Section 8.1 and Definition 8.9) and a *parasymmetric overlay* turns law/state readouts into calibrated "agreement"/"synthesis" meters that remain well–posed even when law and state disagree (Sections 8.2, 8.2.1 and 8.5.4). Boundary soft/edge modes receive a parallel dashboard (Section 8.1.7); anomaly, anyon/CS, fracton, hydrodynamic, SUSY, higher–form and non–invertible cases are all read through sector–specific witnesses but judged by the same band/BRST/plateau standards [114, 52, 112, 118] (Sections 6.12.4, 8.1.2, 8.1.5 and 8.1.8 to 8.1.11 and eq. (7.209)). Net effect: a robust, gauge–clean, scale–aware *operational pipeline* that turns correlators and kernels into falsifiable symmetry diagnoses—uniformly across sectors and boundaries (cf. Definitions 6.274 and 7.15).

What Chapter 8 builds on and where it lives. Everything in Chapter 8 is done *on the band*—i.e., at fixed UV/IR scale tags $(\lambda_{\text{UV}}, \ell)$—and strictly inside the *physical sector* $\mathcal{H}_{\text{phys}}$ (the BRST cohomology). Algebraically, one starts from the scale–tagged, gauge–fixed quadratic

expansion about a symmetric reference vacuum and packages the fluctuations as

$$\delta\hat{\mathbf{U}}_{\lambda_{\mathrm{UV}},\ell} := \big(\delta\hat{\mathbf{\Phi}}_{\lambda_{\mathrm{UV}},\ell},\, \delta\hat{\mathbf{\Theta}}_{\lambda_{\mathrm{UV}},\ell}\big)^{\mathsf{T}}.$$

This defines a *gauge–fixed quadratic kernel* $\mathcal{K}_{\Psi}^{(\lambda_{\mathrm{UV}},\ell)}$. Projecting to $\mathcal{H}_{\mathrm{phys}}$ gives the *physical kernel*

$$\mathcal{K}_{\mathrm{phys}}^{(\lambda_{\mathrm{UV}},\ell)} := \mathsf{P}_{\mathrm{phys}}\, \mathcal{K}_{\Psi}^{(\lambda_{\mathrm{UV}},\ell)}\, \mathsf{P}_{\mathrm{phys}},$$

whose inverses (retarded/advanced/Feynman) are the *physical propagators* $\mathcal{D}_{\mathrm{phys}}^{(\lambda_{\mathrm{UV}},\ell)}$. On $\mathcal{H}_{\mathrm{phys}}$ one has the cohomological inversion $\mathcal{K}_{\mathrm{phys}}\mathcal{D}_{\mathrm{phys}} = \mathbf{1}$, and—crucially—*the pole positions are gauge–parameter independent*. Intuitively, longitudinal/ghost quartets decouple before inversion, and Slavnov–Taylor/Nielsen identities render gauge–parameter shifts BRST–exact, hence invisible in cohomology (cf. Section 7.2.2, Definition 7.15, Proposition 7.16, and eq. (7.209)).

To keep gauge control crisp, the chapter adopts a *Background–Field Method* (BFM) presentation, imposing background Ward identities together with a *band–limited* Nielsen identity for the 1PI functional Γ. Two robust conclusions then follow (on the band): (i) *pole masses are ξ–independent*; (ii) *on–shell visibilities are protected*. Both statements remain stable under admissible regulator moves inside a specified tolerance (cf. Section 7.2.9, Definition 7.59, eqs. (7.19) and (7.27), and Proposition 7.208).

Plateau geometry and certification (scale control). Scale space is equipped with the *log–chart*

$$(u, v) = (\ln \lambda_{\mathrm{UV}}, \ln \ell), \qquad g_{\mathrm{plat}} := du^2 + dv^2, \qquad D_\lambda = \partial_u, \quad D_\ell = \partial_v,$$

and three quantitative *plateau metrics* for any band–readout $O(u, v)$: a *Slope* bound $|\nabla O|$, a *Curvature* bound $\|\nabla^2 O\|$, and an *Oscillation* bound $\operatorname{osc} O$. A band point $(\lambda_{\mathrm{UV}}, \ell)$ is *plateau–stable* if, throughout a small geodesic ball in (u, v), one has

$$|\partial_u O|,\, |\partial_v O| \le \tau_O^{(1)}, \qquad \|\nabla^2 O\| \le \tau_O^{(2)}, \qquad \operatorname{osc} O \le \tau_O^{(\mathrm{osc})}.$$

The chapter proves the *equivalence* (with matched tolerances) between a channelwise/directional certification and this geometric one (cf. Sections 7.3.2 and 7.3.5, Definition 7.31, eqs. (7.28) and (7.46), and Proposition 7.38).

Two stability features matter in practice.

- **Integrated readouts.** If you average a channel readout R_α over a weight w supported inside a certified plateau $\mathfrak{P}$, $\overline{R}_\alpha := \int_{\mathfrak{P}} w\, R_\alpha$, the same slope/curvature/oscillation bounds carry to $\overline{R}_\alpha$ with equal or smaller constants; discrete (grid/box) versions inherit the same control (cf. Proposition 7.146 and eqs. (7.390) and (7.410) to (7.414)).

- **Discrete IR windows.** A curvature–based proxy for the IR window on a grid achieves uniform second–order consistency: the discrete estimator ϕ_h differs from the continuous ϕ by $\mathcal{O}(h^2)$ (plus $\mathcal{O}(\tau^2)$ for the low–pass), and the symmetric–difference in accepted sets has controllably small band–measure (cf. Proposition 7.397).

Witnesses and the quadrant decision rule. The chapter's central deliverable is an *operational decision rule*—applied on a certified plateau—classifying the law/state symmetry situation into the four quadrants (QI–QIV) using *visibilities* (witnesses) computed on $\mathcal{H}_{\text{phys}}$ and on the band:

- a *law–channel* visibility $\Lambda_{\text{law}}(\lambda_{\text{UV}}, \ell)$ that asks whether Ward/Slavnov–Taylor constraints are effectively exact on $\mathfrak{P}$;
- a *state–channel* visibility $\Lambda_{\text{state}}(V; \lambda_{\text{UV}}, \ell)$ that asks whether macroscopic preparation decoheres over a vacuum manifold (large–V limit) or remains coherent (unique vacuum);
- optional *mix–channel* or sector–conditioned variants (e.g., TT vs. longitudinal blocks; spin or charge–resolved) to refine diagnosis while respecting BRST and band operations.

The *canonical quadrant rule* then reads the pair $\big(\Lambda_{\text{law}}, \Lambda_{\text{state}}\big)$ on $\mathfrak{P}$:

- **QI (symmetric law, symmetric state):** $|\Lambda_{\text{law}}| \approx 1$ and $|\Lambda_{\text{state}}| \approx 1$. This is the calibration baseline; the band–prepared physical Hessian is positive with only transverse, positive–norm modes and gauge–independent pole data (no ghosts/tachyons) (cf. Definition 7.685 and Theorem 7.19).
- **QII (symmetric law, asymmetric state):** $|\Lambda_{\text{law}}| \approx 1$ but $\Lambda_{\text{state}}(V) \to 0$ as $V \to \infty$ (vacuum manifold present). Around a chosen vacuum one sees NG modes for broken *global* symmetries; for *gauged* cases would–be NG modes are BRST–paired and vectors become massive (BEH), with quartet decoupling ensuring only physical poles survive (cf. Section 7.7 and Proposition 7.22).
- **QIII (emergent law, symmetric state):** explicit breakers are RG–irrelevant; the Ward deficit and $1 - |\Lambda_{\text{law}}|$ *heal* in the IR with the predicted power law $\sim \ell^{-(\Delta-(d+z))}$; the state stays symmetric, $|\Lambda_{\text{state}}| \approx 1$ (cf. eq. (7.213) and Proposition 7.83).
- **QIV (explicit–breaking law, coherent state):** relevant/marginal breakers keep a *persistent* law deficit on $\mathfrak{P}$, $|\Lambda_{\text{law}}(\ell)| \le 1 - \delta_\star$ (no IR healing), while the state remains coherent $|\Lambda_{\text{state}}| \approx 1$ because a unique non–symmetric vacuum is selected; pseudo–NG masses satisfy GMOR–type relations $m^2_{\text{pNG}} \propto \varepsilon_{\text{eff}}$ (cf. Theorem 7.630, Corollary 7.631, and Section 7.9.11).

All witnesses are *Nielsen–safe* (gauge–parameter independent) because: (i) UV/IR taggers carry ghost number 0 and commute with BRST, (ii) projection to $\mathcal{H}_{\text{phys}}$ removes gauge–exact parts before inversion, and (iii) the BFM/Nielsen algebra keeps band on–shell data invariant (cf. Propositions 7.20 and 7.208 and eq. (7.209)).

How poles are isolated (and kept gauge–safe). Pole extraction is implemented via *Riesz projectors* acting on the transverse–traceless two–point kernel $\Gamma^{(\text{TT})}(p^2)$: encircle a pole at $p^2 = -m_i^2$ with a small contour γ_i and set

$$\mathbb{P}_i \;=\; \frac{1}{2\pi i} \oint_{\gamma_i} \Big(\Gamma^{(\text{TT})}(z)\Big)^{-1} dz, \qquad \widehat{\Gamma}_i := \mathbb{P}_i \, \Gamma^{(\text{TT})} \, \mathbb{P}_i.$$

The eigenvalues of $\widehat{\Gamma}_i$ give m_i^2; by the band Nielsen identity these pole positions are α–independent. Residues may vary with gauge/parametrisation, but *pole locations do not* (cf. Definition 7.286 and eqs. (7.20), (7.21) and (7.438)).

Sector–conditioned witnesses (canonical framework). Chapter 8 systematizes symmetry vs. breaking diagnostics by introducing, for each certified sector $\mathscr{S}$ (bulk, boundary, anisotropic, …), a *witness map* evaluated *on the band* and in the BRST cohomology. A *witness* is a BRST–safe, band–limited functional

$$\mathbf{W}^{[\mathscr{S}]}:\ \mathsf{P}_{\text{phys}}\,\mathfrak{B}_{\lambda_{\text{UV}},\ell}\Big[\text{operators, currents, states on } \mathfrak{P}\Big]\,\mathsf{P}_{\text{phys}} \longrightarrow [0,1], \qquad \Lambda^{[\mathscr{S}]} := \mathbf{W}^{[\mathscr{S}]},$$

constructed so that it is *Nielsen–safe* on shell (gauge–parameter independent; cf. Definitions 6.272 and 6.282 and eqs. (7.201) and (7.209)). Law and state are read as a *witness pair* $\left(\Lambda^{[\mathscr{S}]}_{\text{law}}, \Lambda^{[\mathscr{S}]}_{\text{state}}\right)$ with certified tolerances $\varepsilon_{\text{law}}, \varepsilon_{\text{state}} \in (0,1)$ supplied by the plateau logic (Section 6.12.4, eq. (7.28), and Definition 6.275). Under the chapter's conventions—fixed symmetry G, fixed observation window/order of limits, and BRST–closed probes—the resulting verdict matches the formal quadrant classification on $\mathfrak{P}$ (QI–QIV; Definition 7.685).

Sector–conditioned and boundary variants. Beyond the baseline law/state pair, one may introduce a *mix–channel* witness $\Lambda^{[\mathscr{S}]}_{\text{mix}}$ to monitor cross–couplings (e.g., TT/longitudinal mixing, law–state cross–responses) in a given certified sector $\mathscr{S}$; it is built from the same band–prepared kernels and inherits BRST/Nielsen safety (cf. Section 8.1, Definitions 6.272 and 6.275, and eq. (7.209)). Witnesses may also be *sector–conditioned* (TT vs. longitudinal, spin– or charge–resolved) to disentangle kinematics from conservation–law constraints (Section 8.1 and Definition 8.9). For *boundary* arenas, very–low–frequency transport ("in–/out/through" drivers) can *confound* law–vs–state assessments unless the time–scale hierarchy is respected; some boundary visibilities are excellent for topology/conductance but not faithful for diagnosing law–channel healing or persistent deficits without mode/time–scale filtering (Section 8.1.7 and Lemmas 7.584 and 7.585).

Witnesses and the quadrant decision rule. On a certified plateau, the *operational decision rule* classifies the law/state symmetry situation using visibilities computed on $\mathcal{H}_{\text{phys}}$ and on the band:

- **Law–channel visibility** $\Lambda_{\text{law}}(\lambda_{\text{UV}}, \ell)$: are Ward/Slavnov–Taylor constraints effectively exact on $\mathfrak{P}$?
- **State–channel visibility** $\Lambda_{\text{state}}(V; \lambda_{\text{UV}}, \ell)$: does macroscopic preparation decohere across a vacuum manifold (large–V limit) or remain coherent (unique vacuum)?
- **Optional mix/sector variants** (e.g., TT vs. longitudinal; spin/charge–resolved) to refine diagnosis while preserving BRST and band consistency.

These inputs feed the canonical quadrant rule (Definition 7.685) to return a QI–QIV assignment with the plateau tolerances explicitly tracked.

Boundary/edge witnesses (bulk–boundary parallel). On a certified *boundary* plateau $\mathfrak{P}_\partial$ with a tangential IR window $K^{(L)}_{\mathrm{IR},\partial}$ (band preparation and BRST–closed tagging as in Sections 6.12.4 and 8.1.7 and eq. (7.28)), the tagged boundary Ward identity reads

$$\nabla_\parallel \cdot J^{(\partial)}_\parallel \;=\; S_\partial \quad \text{up to BRST–exact improvements,}$$

and the *law–channel* visibility is defined by

$$\Lambda^{[\partial]}_{\mathrm{law}}(L) \;:=\; 1 - \frac{\big\|S_\partial\big\|_{\mathfrak{P}_\partial}}{\big\|\nabla_\parallel \cdot J^{(\partial)}_\parallel\big\|_{\mathrm{ref},\mathfrak{P}_\partial}} \;\in [0,1],$$

where the boundary norms and the reference normalisation are those fixed in the boundary witness setup (Definition 8.31). The *state–channel* witness uses tolerance semantics on $\mathfrak{P}_\partial$:

$$\begin{aligned} &\text{boundary state symmetric} &&\iff \big|\Lambda^{[\partial]}_{\mathrm{state}}\big| \geq 1-\varepsilon_{\mathrm{state}},\\ &\text{boundary SSB} &&\iff \big|\Lambda^{[\partial]}_{\mathrm{state}}\big| \leq \varepsilon_{\mathrm{state}}. \end{aligned}$$

with $\varepsilon_{\mathrm{law}}, \varepsilon_{\mathrm{state}} \in (0,1)$ taken from the plateau certification (Section 6.12.4 and eq. (7.28)). Quadrant assignments (QI–QIV) mirror the bulk decision rule using the boundary pair $\big(\Lambda^{[\partial]}_{\mathrm{law}}, \Lambda^{[\partial]}_{\mathrm{state}}\big)$, as formalised in Proposition 8.32 and Definition 7.685.

Fermionic witnesses. In the fermionic sector the band–prepared, gauge–fixed two–point kernel $\Gamma_\psi(p)$ is projected to $\mathcal{H}_{\mathrm{phys}}$ and its poles are isolated by Riesz projectors [115, 30],

$$\mathbb{P}_i \;=\; \frac{1}{2\pi i}\oint_{\gamma_i}\big(\Gamma_\psi(z)\big)^{-1}\,dz, \qquad \widehat{\Gamma}_i \;=\; \mathbb{P}_i\,\Gamma_\psi\,\mathbb{P}_i,$$

so that $\mathrm{spec}(\widehat{\Gamma}_i) = \{m_i^2\}$ gives the (gauge–independent) pole masses, while residues encode chiral/parity structure (Nielsen–safe on the band) [114, 38, 112]. The *law* visibility checks the fermionic Ward identities (vector/axial) on the certified plateau [38, 110, 111]; the *state* visibility tests coherence vs. decoherence in macroscopic preparation [32, 112]. In QII (global SSB) NG partners appear in the spectral density [32]; in QIV (explicit breaking) pseudo–NG gaps scale with spurions (GMOR–type) $m^2_{\mathrm{pNG}} \propto \varepsilon_{\mathrm{eff}}$ [112, 32]. See Section 8.1.1, eqs. (7.209) and (7.438), Theorem 7.630, and Corollary 7.631.

Supersymmetry (SUSY) witnesses. Here one compares bosonic and fermionic TT blocks on the band, testing SUSY Ward identities: exact SUSY gives spectral pairing $m_b = m_f$ and matched on–shell visibilities; soft breaking tilts residues but leaves nearby poles; hard breaking splits pole locations [52]. Define a pairing defect

$$\Delta_{\mathrm{SUSY}} \;:=\; \big|m_b - m_f\big|,$$

and read it jointly with the SUSY law visibility (Nielsen–safe) [114, 38, 112]. Healing of $\Delta_{\mathrm{SUSY}} \to 0$ in the IR indicates QIII; a persistent nonzero plateau indicates QIV [32, 112]. See Section 8.1.2 and eqs. (7.19) and (7.209).

p–forms witnesses. For higher–form symmetries the law channel enforces generalized Gauss constraints (higher–form Ward identities),

$$d * F^{(p+1)} \;=\; J^{(p)}_{\mathrm{cons}},$$

while the state channel probes long–range order of brane/line operators. The witness separates Maxwell–like, topological (BF/CS–type), and confining responses by their pole/branch–cut structure and finite–size scalings on the band [110, 111, 32, 112]. See Sections 8.1.3 and 8.1.8.

Higher–spins witnesses. Decompose the spin–s kernel into transverse–traceless and longitudinal parts, $\Gamma^{(s)} \to \big(\Gamma^{(s,\mathrm{TT})}, \Gamma^{(s,\mathrm{L})}\big)$, and locate TT poles with Riesz projectors [115, 30]; healthy sectors exhibit positive–norm TT poles with no ghost contamination [52, 38]. Longitudinal law–deficits shrinking across the plateau indicate QIII (emergent symmetry) [32, 112], whereas regulated mass terms in TT reflect explicit breaking (QIV) [109, 113]. See Section 8.1.4, Definition 7.286, and eq. (7.438).

Hydrodynamics witnesses. In the small–$|p|$ longitudinal block one reads diffusive and sound poles,

$$\omega_{\mathrm{diff}}(p) \approx -\,iD\,p^2, \qquad \omega^{\pm}_{\mathrm{sound}}(p) \approx \pm c_s\,p - i\,\Gamma\,p^2,$$

and extracts Kubo coefficients from band–limited correlators [119, 118]. The law visibility asks whether conserved–current Ward identities hold on $\mathfrak{P}$ [38]; the state visibility tests whether the hydrodynamic modes are coherently supported without boundary artefacts [32, 112]. See Section 8.1.5.

Second sound (matrix formulation). Coupled energy/charge (or entropy) responses define a small–$|p|$ matrix kernel $\mathcal{M}(p)$; a genuine second–sound branch appears as a distinct propagating pole after diagonalization,

$$\det \mathcal{M}(\omega, p) \;=\; 0 \quad \Rightarrow \quad \omega_{\mathrm{2nd}}(p) = \pm c_2\,p + \cdots .$$

The witness includes falsification tests (decoupling conditions) to avoid mis–tagging slow diffusion as a wave [119, 118]. See Section 8.1.6.

Bound soft/edge modes witnesses. With physical boundary conditions imposed, the *edge kernel* $\Gamma^{(\partial)}(k_\parallel, \omega)$ is prepared on the band and projected to $\mathcal{H}_{\mathrm{phys}}$ [114, 52]. Edge poles/zero modes are isolated by Riesz projectors [115, 30],

$$\mathbb{P}^{(\partial)}_i \;=\; \frac{1}{2\pi i}\oint_{\gamma_i}\Big(\Gamma^{(\partial)}(z)\Big)^{-1}\,dz, \qquad \widehat{\Gamma}^{(\partial)}_i := \mathbb{P}^{(\partial)}_i\,\Gamma^{(\partial)}\,\mathbb{P}^{(\partial)}_i,$$

so that $\det \widehat{\Gamma}^{(\partial)}_i(\omega_i, k_\parallel) = 0$ yields chiral branches $\omega_i(k_\parallel) = v_i k_\parallel + \cdots$ when present (Nielsen–safe on the band) [114, 38]. The *law* witness enforces the tagged edge Ward identity (anomaly–inflow form) and its BRST–closed improvements [110, 111, 52],

$$\partial_t \rho_\partial + \nabla_\parallel \cdot j^{(\partial)}_\parallel \;=\; S_\partial, \qquad \Lambda^{[\partial]}_{\mathrm{law}}(L) = 1 - \frac{\|S_\partial\|_{\mathfrak{P}_\partial}}{\|\nabla_\parallel \cdot j^{(\partial)}_\parallel\|_{\mathrm{ref},\mathfrak{P}_\partial}},$$

while the *state* witness diagnoses coherent vs. decohering edges from the sharpness of the edge poles under size/disorder scans on the certified boundary plateau $\mathfrak{P}_\partial$ [32, 112] (cf. Section 8.1.7, Definition 8.31, and Proposition 8.32).

Anyons (Chern–Simons) witnesses. In a band–prepared Chern–Simons (CS) sector, the Hall response σ_H and braiding phases θ provide quantized law–channel diagnostics that are stable on a certified plateau [32, 112, 24, 25, 23]:

$$\left|\sigma_H - \frac{k}{2\pi}\right| \le \varepsilon_{\text{law}}, \qquad \theta_{ab} = 2\pi\,(K^{-1})_{ab} \pmod{2\pi},$$

with deviations indicating explicit breaking or non–topological mixing [112]. The *state* witness separates bulk topological mass from boundary chiral modes by comparing bulk TT poles with edge dispersions in the same band setting; both witnesses inherit gauge–parameter independence via the band Nielsen control [114, 38, 112] and capture anomaly–inflow–type edge constraints [110, 111] (cf. Section 8.1.8 and eq. (7.19)).

Fractons witnesses. Restricted mobility is certified by *higher–moment Ward constraints* for charge and dipole densities on the band [112, 32, 38]:

$$\partial_t \rho + \nabla\cdot J = 0, \qquad \partial_t P_i + \partial_j J^{(2)}_{ij} = 0, \quad P_i := \int x_i\,\rho,$$

together with the *absence* (or parametrically strong suppression) of poles in the driven dipole/quadrupole channels after projection to $\mathcal{H}_{\text{phys}}$ [32, 112]. The *law* witness checks the moment–conservation identities on $\mathfrak{P}$ [38]; the *state* witness verifies that preparation respects subdimensional kinematics (no spurious mobile carriers) (cf. Section 8.1.9).

Higher–forms and non–invertible symmetries. For a p–form symmetry with conserved $(p{+}1)$–form current $J^{(p+1)}$, the law–channel witness enforces the higher–form Ward identity on the band [38, 112, 32],

$$d * J^{(p+1)} = 0,$$

while the state–channel witness uses defect/'t Hooft operators $\mathcal{W}(\Sigma^p)$ (surfaces/lines) to read long–range order and fusion/selection rules [32, 24, 25, 23]. Non–invertible structure is probed by defect composition [112, 32],

$$\mathcal{D}_a \circ \mathcal{D}_b \;=\; \sum_c N_{ab}^{\;c}\,\mathcal{D}_c,$$

and its band–stable plateaus: IR healing of these constraints ($\Rightarrow$ QIII) vs. persistent violations ($\Rightarrow$ QIV) is read from defect–conditioned kernels [112, 32] (cf. Section 8.1.10).

Anomaly witnesses. Background–field variations convert 't Hooft/Wess–Zumino consistency into operational law–channel checks [114, 112]:

$$\delta_\alpha \Gamma_{\text{band}}[A] \;=\; \int \alpha\,\mathcal{A}[A],$$

with $\mathcal{A}[A]$ the anomaly functional extracted on the band [110, 111]. Plateau robustness (small slope/curvature/oscillation) renders the inferred coefficients scheme–stable; UV/IR matching of $\mathcal{A}$ decides if the symmetry is realized, broken, or requires topological sectors [32, 112]. Nielsen identities guarantee gauge–parameter independence of the on–shell readouts [114, 38, 112] (cf. Section 8.1.11 and eq. (7.19)).

Non–equilibrium (Floquet/Lindblad) witnesses. For periodic drive of period T, the law–channel check uses the Floquet operator [22]

$$U_F(T) \;=\; \mathcal{T}\exp\!\Big(-i\int_0^T H(t)\,dt\Big), \qquad U_F\,|\phi_n\rangle = e^{-i\varepsilon_n T}\,|\phi_n\rangle,$$

and stroboscopic Ward constraints on $\Gamma_{\text{band}}\big|_{\text{Floquet}}$ [114, 38]. In open systems the Liouvillian $\mathcal{L}$ governs dynamics, $\dot\rho = \mathcal{L}\rho$, with spectrum $\{\lambda_a\}$ read on the band; the state witness compares coherence vs. heating/decoherence by tracking spectral gaps and steady–state projectors [118, 115, 30]. Integrated–readout versions keep plateau certification despite time dependence [112, 32] (cf. Section 8.1.12 and Proposition 7.146).

The Synthesis of Laws and States (Section 8.2). This section provides a single *operational* stage on which the *law*– and *state*–channel diagnostics can be read *together* without logical dead–ends when they differ. Concretely, the quadrant dashboard is evaluated only on a *certified arena* (shared plateau, BRST–closed tagging, sector witnesses available; cf. Section 6.12.4, eq. (7.28), and Definition 6.275) and packaged in a paraconsistent meta–layer that records co–tenable modalities. On the band and inside the physical sector,

$$(\Lambda_{\text{law}}, \Lambda_{\text{state}}) \;\in\; [0,1]^2, \qquad \mathbb{D} := \{x \in [0,1] \mid x \geq 1-\varepsilon_\bullet\}$$

is the set of designated values (channel–wise tolerances from the plateau), and a non–explosion diagnostic

$$\Pi_{pc}(\Lambda_{\text{law}}, \Lambda_{\text{state}}) \;:=\; \mathbf{1}_{\mathbb{D}}(\Lambda_{\text{law}})\,\mathbf{1}_{[0,1]\setminus\mathbb{D}}(\Lambda_{\text{state}}) \;+\; \mathbf{1}_{\mathbb{D}}(\Lambda_{\text{state}})\,\mathbf{1}_{[0,1]\setminus\mathbb{D}}(\Lambda_{\text{law}})$$

flags controlled "both/and" situations without collapsing the readout; the canonical quadrant decision remains governed by the usual rule (QI–QIV) applied on a certified plateau (Definition 7.685). Interferometric overlays and duality lifts are required to be *dashboard–invariant*, in the sense that any admissible overlay $\mathcal{O}$ that preserves certification (band/BRST closure) satisfies

$$\mathcal{O}:\;\; (\Lambda_{\text{law}}, \Lambda_{\text{state}}) \mapsto (\Lambda'_{\text{law}}, \Lambda'_{\text{state}}) \quad \text{with} \quad \mathbf{1}_{\text{QI–QIV}}\Big(\Lambda_{\text{law}}, \Lambda_{\text{state}}\Big) = \mathbf{1}_{\text{QI–QIV}}\Big(\Lambda'_{\text{law}}, \Lambda'_{\text{state}}\Big),$$

so the quadrant assignment is stable under admissible overlays (cf. Section 8.5).

Sector–conditioned realisation and operational template (Section 8.1). Given a sector $\mathscr{S}$ with instrumentation $\mathcal{I}^{[\mathscr{S}]}$ and witness set $\mathbf{W}^{[\mathscr{S}]}$, the synthesis is instantiated as follows. *Step 0* (arena and certification): fix the arena $\mathcal{A} \in \{\mathfrak{P}, \mathfrak{P}_\partial\}$, the IR knob r, and certify

the plateau(s) using the band functor and BRST–closed taggers ($\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}$; $P_x(\lambda_{\mathrm{UV}}), K_{\mathrm{IR}}^{(\ell)}$; cf. Definitions 6.278, 6.280 and 6.282 and eq. (7.28)). Work on the log–chart

$$(u,v) = (\ln \lambda_{\mathrm{UV}}, \ln r), \qquad g_{\mathrm{plat}} = du^2 + dv^2.$$

Step 1 (witness pair): build the sector pair

$$\Big(\Lambda_{\mathrm{law}}^{[\mathscr{S}]}(u,v),\ \Lambda_{\mathrm{state}}^{[\mathscr{S}]}(u,v)\Big) \ := \ \Big(\mathbf{W}_{\mathrm{law}}^{[\mathscr{S}]}\big[\mathsf{P}_{\mathrm{phys}}\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}[\cdot]\mathsf{P}_{\mathrm{phys}}\big],\ \mathbf{W}_{\mathrm{state}}^{[\mathscr{S}]}\big[\mathsf{P}_{\mathrm{phys}}\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}[\cdot]\mathsf{P}_{\mathrm{phys}}\big]\Big),$$

which is Nielsen–safe on shell by construction ($\partial_\xi, \partial_{\alpha_{\mathrm{gf}}}$ kill physical readouts; eq. (7.209)). The canonical decision rule then applies on $\mathcal{A}$ with the certified tolerances (Definition 7.685 and Section 6.12.4).

Parasymmetric Synthesis of Laws and States (Section 8.2.1). Locally (at an *anchor*), each channel is resolved into a minimal two–mode basis $\{|\mathrm{Sym}\rangle, |\mathrm{Break}\rangle\}$. The parasymmetric overlay forms even/odd combinations that read joint coherence vs. law–state skew with *meter–level* operators:

$$P_{\mathrm{para}}^{(a)} = |+\rangle\langle+|, \quad P_{\mathrm{anti}}^{(a)} = |-\rangle\langle-|, \qquad |\pm\rangle := \tfrac{1}{\sqrt{2}}\Big(|\mathrm{Sym}\rangle \pm |\mathrm{Break}\rangle\Big), \quad a \in \{\mathrm{Law}, \mathrm{State}\}.$$

and, on the relational space $L \otimes S$, Bell–type projectors select "coherent agreement" (I/IV diagonal) vs. "coherent opposition" (II/III diagonal). The corresponding meters,

$$v_{\mathrm{Synthesis}}^{(a)} := \mathrm{Tr}\Big(P_{\mathrm{para}}^{(a)}\rho^{(a)}\Big), \qquad v_{\mathrm{Agreement}}^{(LS)} := \mathrm{Tr}\Big(P_{\mathrm{para}}^{(LS)}\rho^{(LS)}\Big),$$

are computed *on the band* and *in* $\mathcal{H}_{\mathrm{phys}}$, and inherit the plateau/Nielsen guarantees of their ingredients. These anchor–level overlays feed back into the dashboard, providing a concrete, certified mechanism for quadrant readouts that respects the chapter's operational constraints.

Putting them together: sector resolver and stability. The chapter defines a sector–wise resolver that maps the family of sector readouts to labels (quadrant + explanatory class) and proves *stability* under: (i) admissible gauge–fermion retunings (Nielsen–flatness), (ii) BRST–closed retunings of the UV/IR taggers (P_x, K_{IR}) that preserve certification, and (iii) certified coarsenings of the plateau domain. Symbolically,

$$\mathcal{R}^{[\mathscr{S}]} : \ \Big\{\Lambda_{\bullet}^{[\mathscr{S}]}(u,v)\Big\}_{(u,v)\in\mathcal{A}} \ \longmapsto \ (\mathrm{QI–QIV},\ \mathrm{class}) \quad \text{with} \quad \partial_\xi \mathcal{R}^{[\mathscr{S}]} = \partial_{\alpha_{\mathrm{gf}}} \mathcal{R}^{[\mathscr{S}]} = 0,$$

and with inclusion relations preserved under the geometric/log–chart plateau definitions (Sections 6.12.4 and 8.1 and eq. (7.28)).

Summary. Section 8.2 supplies the meta–logic and dashboard for joint law–state reading on certified arenas; Section 8.2.1 gives the *parasymmetric* anchor–level realisation; and the sector template $\big(\mathscr{S}, \mathcal{I}^{[\mathscr{S}]}, \mathbf{W}^{[\mathscr{S}]}\big)$ specifies how to implement both—witnesses, tags, and plateaus—in any sector (Section 8.1).

Parasymmetric Overlay of Boundary Soft/Edge Modes (worked example) (Section 8.5.4). Soft/edge modes often carry clearer symmetry fingerprints than the bulk. This overlay upgrades the law–vs–state dashboard to treat the *boundary* as a first–class certified arena, using the same band/plateau and BRST/Nielsen–safe logic as in the bulk (cf. Sections 6.12.4 and 8.1.7 and eqs. (7.28) and (7.209)).

Boundary calibration: witnesses → density operators. On a certified boundary plateau $\mathfrak{P}_\partial$ with tangential IR window $K^{(L)}_{\mathrm{IR},\partial}$ and spectral projector $P_x(\lambda_{\mathrm{UV}})$ (cf. Definitions 6.278 and 6.280), define the *boundary parasymmetric calibration* as a CPTP map

$$\kappa^{[\partial]}:\ \Big(\Lambda^{[\partial]}_{\mathrm{law}}(L),\,\Lambda^{[\partial]}_{\mathrm{state}}(L);\,\mathcal{W}^{[\partial]},\,\mathcal{Z}^{[\partial]}\Big)\longrightarrow\Big(\rho^{(L)[\partial]},\,\rho^{(S)[\partial]},\,\rho^{(LS)[\partial]}\Big),\qquad (\textit{Definition } 8.133),$$

evaluated *on the band* and in the physical sector $\mathsf{P}_{\mathrm{phys}}\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}[\cdot]\mathsf{P}_{\mathrm{phys}}$ (cf. Definitions 6.272 and 6.282). BRST closure yields *Nielsen flatness* (gauge–parameter independence on shell; eq. (7.209)).

Meters on the boundary: synthesis and agreement. Using parasymmetric projectors at each anchor and Bell–type projectors on the $L\otimes S$ space, define the four boundary meters (cf. Definition 8.134):

$$v^{(L)[\partial]}_{\mathrm{Synthesis}}=\mathrm{Tr}\Big(P^{(L)}_{\mathrm{para}}\rho^{(L)[\partial]}\Big),\quad v^{(S)[\partial]}_{\mathrm{Synthesis}}=\mathrm{Tr}\Big(P^{(S)}_{\mathrm{para}}\rho^{(S)[\partial]}\Big),$$
$$v^{(LS)[\partial]}_{\mathrm{Synthesis}}=\mathrm{Tr}\Big(P^{(LS)}_{\mathrm{para}}\rho^{(LS)[\partial]}\Big),\qquad v^{(LS)[\partial]}_{\mathrm{Agreement}}=\mathrm{Tr}\Big(P^{(LS)}_{\Phi,\mathrm{para}}\rho^{(LS)[\partial]}\Big).$$

These are normalised so 1 = coherent "both/and," 1/2 = *mixture baseline*, and 0 = coherent "anti–both." Intuitively, the *Synthesis* meters detect coherent opposition (II/III diagonal), whereas the *Agreement* meter detects coherent agreement (I/IV diagonal).

Cross–coherence wired to edge operators. A boundary cross–coherence lemma gives an explicit off–diagonal entry (cf. Lemma 8.135):

$$\rho^{(LS)[\partial]}_{12}\ \propto\ \frac{\big\langle S_\partial,\ \mathcal{O}_\partial\big\rangle_{\mathfrak{P}_\partial}}{\sqrt{\langle S_\partial,S_\partial\rangle_{\mathfrak{P}_\partial}\,\langle\mathcal{O}_\partial,\mathcal{O}_\partial\rangle_{\mathfrak{P}_\partial}}},$$

with S_∂ the boundary state readout and $\mathcal{O}_\partial$ a matched edge operator (edge current, soft charge density, memory/vertex operator). Consequently,

$$v^{(LS)[\partial]}_{\mathrm{Synthesis}}=\tfrac12+\mathrm{Re}\ \rho^{(LS)[\partial]}_{12},\qquad v^{(LS)[\partial]}_{\mathrm{Agreement}}=\tfrac12+\mathrm{Re}\ \rho^{(LS)[\partial]}_{\Phi,12},$$

so the meters are directly tied to concrete edge observables.

Quadrant patterns at the boundary. Thresholds $\tau_{\mathrm{agr}},\tau_{\mathrm{syn}}\in(0,\tfrac12)$ fix the correspondence (cf. Proposition 8.136):

$$\text{QI or QIV}\ \Rightarrow\ v^{(LS)[\partial]}_{\mathrm{Agreement}}\geq\tfrac12+\tau_{\mathrm{agr}},\qquad \text{QII or QIII}\ \Rightarrow\ v^{(LS)[\partial]}_{\mathrm{Synthesis}}\geq\tfrac12+\tau_{\mathrm{syn}}.$$

In boundary–QIV (explicit breaking) the *agreement* meter stays high as L grows and the edge spectral ledger displays a pNG band on $\mathfrak{P}_\partial$; in boundary–QII (edge SSB) one finds an edge Goldstone and $v^{(S)[\partial]}_{\mathrm{Synthesis}}\to\frac12$ (mixture baseline); in boundary–QIII the *synthesis* meter rises monotonically as the boundary law deficit $d^{[\partial]}_{\mathrm{law}}(L)\downarrow$ (IR healing).

Operational recipe. As a procedure (cf. Definition 8.137):

1. *Classify* the boundary sector with a resolver $\mathcal{R}^{[\partial]}$ using the boundary witnesses (cf. Definition 8.31 and Proposition 8.32).

2. *Calibrate* $\kappa^{[\partial]}$ and compute the meters $\upsilon^{(L)[\partial]}_{\text{Synthesis}}$, $\upsilon^{(S)[\partial]}_{\text{Synthesis}}$, $\upsilon^{(LS)[\partial]}_{\text{Synthesis}}$, $\upsilon^{(LS)[\partial]}_{\text{Agreement}}$.

3. *Threshold* with $\tau_{\text{agr}}, \tau_{\text{syn}}$ to decide I/IV vs. II/III; the 1/2 baseline flags local "bothness" (incoherent mixture).

4. *Cross–check ledgers:* QII $\Rightarrow$ edge Goldstone & conserved/improved edge current; QIII $\Rightarrow$ adjoint divergence vanishes along L and no NG/pNG.

5. *Steer* by varying L (and boundary conditions) to test healing vs. persistence. In open settings ensure the relevant projectors commute with the evolution, or satisfy $\mathcal{L}^{\dagger}(P) = 0$, so meters are conserved/auditable.

Why this overlay matters. It disambiguates bulk–boundary puzzles by scanning the single tangible knob L, turning tolerance–form boundary witnesses (Section 8.1.7) into instrument–grade coherence diagnostics with the same plateau certification and Nielsen flatness. It is the edge realisation of the global synthesis (Section 8.2), expressed in meters that can be audited on certified boundary arenas.

Chapter 8 delivers a *practical, falsifiable pipeline* for deciding whether symmetry is realized, spontaneously broken, emergent, or explicitly violated, while surviving the standard traps of *gauge dependence*, *ghost contamination*, and *scale drift* [114, 38, 117, 32, 112]. The construction fixes all computations *on the band* and *in the physical BRST cohomology* [114, 52] (cf. Definitions 6.272 and 6.282 and Proposition 7.20) and then builds *witnesses*—visibilities in $[0, 1]$—that answer, channel by channel, whether the *laws* are effectively symmetric and whether the *state* remains coherently symmetric [112, 32] (cf. Definition 6.275). Trustworthiness comes from: (i) *Nielsen safety* (gauge–parameter independence on shell) [114, 38, 112] (eqs. (7.201) and (7.209) and Proposition 7.208), (ii) *cohomological inversion* that decouples longitudinal/ghost pieces before inversion [117, 52] (Proposition 7.16 and Definition 6.274), (iii) *Riesz projectors* to extract gauge–independent pole locations [115, 30] (eq. (7.438) and Definition 7.286), and (iv) *plateau certification* in a UV/IR log–scale geometry—small slope/curvature/oscillation—with integrated–readout and discrete–IR controls [32, 112] (Section 6.12.4, eq. (7.28), and Propositions 7.146 and 7.397). With these in hand, the *canonical decision rule* assigns each certified bandpoint to one of the four quadrants (QI–QIV), cleanly separating unbroken, SSB, emergent, and explicit–breaking regimes (Definition 7.685).

Conclusions (synthesis and extensibility). Equally important is the *synthesis* layer and its *extensibility*. The same witness logic is made *sector–conditioned* (TT vs. longitudinal, spin/charge, boundary vs. bulk; Section 8.1 and Definition 8.9) and upgraded by a *parasymmetric overlay* that turns law/state readouts into calibrated "agreement"/"synthesis" meters—well–posed even when law and state disagree (cf. Sections 8.2, 8.2.1 and 8.5.4). Boundary soft/edge modes receive a first–class dashboard, and anomaly, anyon/CS, fracton, hydrodynamic, SUSY, higher–form and non–invertible cases all plug into the same band/BRST/plateau standards [110, 111, 32, 118, 52, 112] (Sections 8.1.2, 8.1.5 and 8.1.8 to 8.1.11). Net effect: a robust, gauge–clean, scale–aware *operational pipeline* that turns

correlators and Ward identities into falsifiable symmetry diagnoses—uniformly across sectors and boundaries [38, 112] (cf. Definitions 6.274 and 7.15).

Chapter 9: The Quanta of Fields

Where Chapter 9 "lives" in scale and what is admissible Chapter 9 partitions the analysis by scale and specifies *what operations are admissible at each level*. There are three regimes: the *PQS core* (no meters/certifications), the *pre-physical band* $[\ell_{\mathrm{PQS}}, \ell_P)$ (operator-level audits only), and the *realized regime* $\ell \geq \ell_P$ (first certified plateaux $\mathfrak{P}$ and projection to the physical BRST cohomology $H^0(\hat{Q}_{\mathrm{BRST}})$). In particular, *plateau certification* $\mathfrak{P}$ and evaluation of physical, channelized visibilities $\left(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}}\right)$ are allowed only in the realized regime; SynTh and parasymmetric meters act only on H^0 and remain Σ-causal and BRST-safe (cf. Definition 9.1, Chapter 9, Lemma 9.3, and Sections 9.5 and 9.16).

A scale-to-sector reading is provided as follows: for $\ell \geq \ell_P$ one passes to physical poles/residues on H^0—e.g. in the Gaiamiti ($\Phi\Phi$) block, the massless spin-2 Goldstone (graviton) and gapped geometric radials; in the Tantrakyma ($\Theta\Theta$) block, NG/pNG/Higgs content is resolved by the quadrant logic (QI–QIV). For $\ell \gg \ell_P$ or $\ell \sim \mathcal{L}_U$, the same H^0 kernels govern, respectively, IR/classical and cosmological coarse-grain limits (consistently with the earlier framework) (cf. Remark 9.4 and Section 9.18.6).

Pre-physical Symmetry Reduction (PSR). PSR is the operator-level stage, valid for relational scales $\ell < \ell_P$, where symmetry content is analysed *prior* to any physical projection or meters. The analysis is carried out entirely in the Σ-centric language using the unified tensor $\hat{\Sigma}_{\mu\nu} = \hat{g}_{\mu\nu} + \hat{t}_{\mu\nu}$ (cf. Definition 5.25) and the Σ-cones determined by the diagnostic realized reference configuration $\bar{\Sigma}_{\mu\nu}$ (cf. Definition 5.77). Within this band-prepared setting, admissible taggers $P_x(\lambda_{\mathrm{UV}})$ and $K^{(\ell)}_{\mathrm{IR}}$ are applied [32, 112], BRST-exact gauge fixing and Nielsen safety are enforced [52, 117, 120, 121, 114], and typed ledgers are assembled for later realized reads (cf. Section 6.12.7). In this regime, plateaux $\mathfrak{P}$ are not certifiable and no projection to the physical cohomology $H^0(\hat{Q}_{\mathrm{BRST}})$ is performed [52] (cf. Definition 9.58).

Outputs and eligibility. Operationally, PSR identifies broken directions and builds Σ-weighted Gram operators to solve generalized eigenproblems, yielding Σ-orthonormal principal systems (Apeiron–Kymon creators) as robust, gauge-clean *candidates* for modes and channels—still pre-physical in status [115, 30] (cf. Definition 5.25). These outputs function as eligibility data: they acquire physical meaning only upon entering the realization regime $\ell \geq \ell_P$, where a plateau $\mathfrak{P}$ is certified [32, 112] (cf. Definition 9.58) and the projection to $H^0(\hat{Q}_{\mathrm{BRST}})$ is taken [52, 117]. There, meters and visibilities $(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}})$ are evaluated within the witness framework on $\mathcal{H}_{\mathrm{phys}}$ [38, 112] (cf. Section 8.1 and Definition 6.275).

Σ-centric upgrade. Chapter 9 recasts the entire Pre-physical Symmetry Reduction (PSR) $\rightarrow$ realization workflow in the unified chronogeometric language of the operator-level tensor

$$\hat{\Sigma}_{\mu\nu} \;:=\; \hat{g}_{\mu\nu} + \hat{t}_{\mu\nu},$$

(cf. Definition 5.25) together with its realized expectation on the diagnostic realized reference configuration,

$$\bar{\Sigma}_{\mu\nu} \;:=\; \langle\, \hat{\Sigma}_{\mu\nu} \,\rangle \;=\; \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu},$$

(cf. Definition 5.26). Hence any construction that was formerly stated "triad-wise" (separately in $\bar{g}$ and $\bar{t}$; cf. Section 4.10.2) is now expressed intrinsically at the Σ-level (i.e., $\bar{\Sigma} = \bar{g} + \bar{t}$ via Definition 5.25), while all causal and variational statements are understood with respect to $\bar{\Sigma}$ and the Σ-cones it determines (cf. Definitions 5.77 and 6.7 and Section 5.4).

Regime stratification (PQS-anchored). The programme is stratified by relational scale, anchored at the PQS core (cf. Section 4.18) and flowing through pre-physical, realized, IR/classical, and cosmological domains:

$$\begin{aligned}\text{PQS core} \;\rightsquigarrow\; \big[\ell_{\mathrm{PQS}}, \ell_P\big) \text{ (pre-physical)} \;\rightsquigarrow\; \\ \ell \geq \ell_P \text{ (realization)} \;\rightsquigarrow\; \ell \gg \ell_P \text{ (IR/classical)} \;\rightsquigarrow\; \ell \sim \mathcal{L}_U \text{ (cosmological)}\,.\end{aligned}$$

Only for $\ell \geq \ell_P$ can a plateau $\mathfrak{P}$ be certified (see Definitions 6.300, 7.47 and 9.58 and Section 6.12.4); below ℓ_P the analysis is strictly pre-physical/operator-level, admitting neither $\mathfrak{P}$ nor physical meters or projections. At eligible scales, BRST projection to the physical sector is well defined and all physical readouts are taken on

$$\mathcal{H}_{\mathrm{phys}} \;=\; H^0(\hat{Q}_{\mathrm{BRST}})\,,$$

with cohomological/Nielsen hygiene inherited from the band-prepared setting (cf. Definitions 6.278, 6.280 and 6.282, Principle 6.1, and Propositions 6.214 and 7.16). Physical witness evaluations then proceed on $\mathcal{H}_{\mathrm{phys}}$ using the established meters and decision rules (cf. Section 8.1 and Definitions 6.275 and 7.685).

Operational eligibility and workflow by regime. *(i) PQS core:* no operational diagnostics apply. *(ii) Pre-physical band* $\big[\ell_{\mathrm{PQS}}, \ell_P\big)$*:* one may employ band-tagging (cf. Definitions 6.278, 6.280 and 6.282), perform Σ-cone causality checks against the realized cones (cf. Definitions 5.77 and 5.122), enforce BRST/Nielsen hygiene (cf. Principle 6.1, Proposition 6.214, and eq. (7.209)), and prepare typed ledgers for later realized reads (cf. Section 6.12.7); however, there is no $\mathfrak{P}$ in this regime, and thus no physical meters. *(iii) Realization* $\ell \geq \ell_P$*:* certify a plateau $\mathfrak{P}$ (cf. Definitions 6.300, 7.47 and 9.58 and Section 6.12.4), project to H^0, evaluate the physical visibilities $(\Lambda_{\mathrm{law}}, \Lambda_{\mathrm{state}})$ within the witness framework (cf. Section 8.1 and Definitions 6.275 and 7.685), and run SynTh/typed meters exclusively on $\mathcal{H}_{\mathrm{phys}}$ (cf. Sections 8.2 and 8.2.1). In every case, computations and causality statements are articulated in the Σ-centric formulation, ensuring compatibility with the Σ-causal structure (cf. Section 5.4 and Definition 6.7) and the certified-plateau criteria referenced above.

Correlator amplitude, band-locality, and Σ–chronogeometry To compute observables, Chapter 9 fixes the *Fourfold correlator amplitude* and its *normalizations* on the band:

$$\mathsf{G}(x, x'; \psi_1, \psi_2) := \Big\langle \mathring{\mathbf{\Psi}} \Big|\, \hat{G}_\Lambda\Big(\mathfrak{B}_x, \mathfrak{B}_{x'}\Big)\, [\psi_1^*, \psi_2] \,\Big|\, \mathring{\mathbf{\Psi}} \Big\rangle, \qquad N(\psi_1, x) := \mathsf{G}(x, x; \psi_1, \psi_1)^{1/2},$$

with frame alignment via $\mathcal{U}(x \leftarrow x'; \gamma)$ and *band-limited locality* enforced by the tag $\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}$. This construction is compatible with the Fourfold bundle and graded kinematics, preserving Hermiticity/covariance (cf. Definitions 9.5, 9.7, 9.10 and 9.18, Proposition 9.6, eqs. (9.1) and (9.36), and Lemma 9.11).

From these ingredients the *operator-valued chronogeometry* $\hat{\Sigma}_{\mu\nu}$ is built *on the band* by combining correlator-based distances $(d_{\mathrm{corr}}, d_{\mathrm{vac}}, d_{\mathrm{spec}})$ with the spectral generator $\hat{D}$; this is the Σ-object that underwrites cones/hyperbolicity and all subsequent Σ-aware meters (cf. Definitions 9.20 and 9.98, eqs. (9.4) and (9.41), and Proposition 9.108).

Σ-weighted broken-sector mode extraction (pre-physical). In the pre-physical, operator-level stage (PSR; $\ell < \ell_P$), broken directions are isolated by Σ-based contrasts that replace earlier distance-only diagnostics. Concretely, contrasts are formed in the Σ-centric language (cf. Definitions 5.25 and 5.26) and organised using the quadrant logic for symmetry status (cf. Theorem 6.231 and Definition 7.685), providing a Σ-aware selection of the broken-generator set $\mathfrak{B}$. This replaces purely $\bar{g}$-based criteria from the triadic split (cf. Section 4.10.2) and ensures compatibility with the realized causal structure determined by $\bar{\Sigma}$ (cf. Definition 5.77 and Section 5.4).

Step A: find breakings. Given the Σ-centric correlator stack (cf. Definition 6.4 and Section 6.1.1), Σ-contrasts are applied to diagnose departures from the symmetric ledger, yielding the set of broken generators $\mathfrak{B}$. Band hygiene (BRST/Nielsen) is maintained throughout to ensure gauge-stable eligibility data (cf. Principle 6.1, Proposition 6.214, eq. (7.209), and Definitions 6.278, 6.280 and 6.282).

Step B: graded tangents & Σ-weighted Gram operators. For each $X \in \mathfrak{B}$, compute the graded tangent variations $\delta_X \hat{G}_{\Phi\Phi}$ and $\delta_X \hat{G}_{\Theta\Theta}$ of the unified inter-modal correlators (cf. Definition 6.4 and Section 6.1.1) and assemble the corresponding Σ-weighted Gram operators C_Φ and C_Θ. The principal directions are obtained from the generalized eigenproblems

$$C_\Phi\, u_a = \lambda_a\, \hat{\Sigma}^{(\Phi)}\, u_a, \qquad C_\Theta\, v_b = \mu_b\, \hat{\Sigma}^{(\Theta)}\, v_b,$$

posed in the Σ-pre-Hilbert modules determined by the operator tensor $\hat{\Sigma}_{\mu\nu} = \hat{g}_{\mu\nu} + \hat{t}_{\mu\nu}$ (cf. Definition 5.25). By construction these problems are gauge/frame covariant and band-regular (cf. Definitions 6.278 and 6.280), and are compatible with the bundle-theoretic packaging of excitations (cf. Section 6.4 and Definition 6.192).

Step C: principal systems and Apeiron/Kymon creators. Solutions furnish Σ-orthonormal principal systems $\{u_a\} \subset \mathcal{N}_\Phi^{\mathrm{pre}}$ and $\{v_b\} \subset \mathcal{N}_\Theta^{\mathrm{pre}}$ with non-negative spectra, together with Σ-weighted block factorizations that define the Apeiron/Kymon creators (normalisation governed by the Σ-inner product induced from $\hat{\Sigma}$; cf. Definition 5.25). The Σ-weighting renders principal directions intrinsically sensitive to both amplitude curvature and temporal phase-flow via the quadratic form

$$\hat{Q}_x[v] \;=\; v^\mu v^\nu\, \hat{\Sigma}_{\mu\nu}(x) \quad (\text{cf. } \textit{Definitions } 5.25 \textit{and } 6.7),$$

ensuring that $\bar{g}$- and $\bar{t}$-sector information is coherently combined. Off-diagonal intermodal entries in $\hat{G}_{\Theta\Theta}$ are treated faithfully by the same Σ-weighted eigenproblem; when $[\hat{\Sigma}^{(\Theta)}, \delta_X \hat{G}_{\Theta\Theta}] = 0$ the problem block-diagonalises channelwise, otherwise it reduces to a compact positive operator K_Θ with a globally diagonalizable spectrum (cf. Section 6.1.1). Temporal-sector dominance isolates the torsional (Chrono–Kymon) channels as a distinguished type within the Tantrakyma sector (cf. Section 6.1 and Definition 6.141); in the correlator-only or $\hat{\Sigma} \propto \mathbb{I}$ limits the construction collapses to the familiar SVD.

Phase–amplitude split and stability. The Σ-based principal directions carry a phase/amplitude character inherited from the $\bar{t}/\bar{g}$ split (cf. Section 4.10.2), and their spectra and normalisations vary continuously under band deformations. On certified plateaux $\mathfrak{P}$, degeneracy splittings are $\mathcal{O}(\varepsilon)$ with respect to the plateau tolerances (cf. Definitions 6.300, 7.47 and 9.58, Section 6.12.4, and Proposition 7.38).

Status note (pre-physical). All extractions above are pre-physical eligibility data: physical pole structure and residues are to be read only after entering the realization regime $\ell \geq \ell_P$, certifying a plateau $\mathfrak{P}$ and projecting to the physical cohomology $H^0(\hat{Q}_{\mathrm{BRST}})$; the resulting channels persist consistently with Ward/Nielsen identities on $\mathcal{H}_{\mathrm{phys}}$ (cf. Definitions 6.275 and 9.58, eqs. (7.20) and (7.209), and Section 8.1).

Σ–contrasts, continuity, and stability under band deformations Given $\hat{\Sigma}$, the chapter works with the quadratic form $\hat{Q}_x[v] = v^\mu v^\nu \hat{\Sigma}_{\mu\nu}(x)$ and defines *pre-physical, Σ–based contrasts* for the law and state channels. A key technical point is *well-posedness and stability*: for band-regular, Hermitian SOT–C^2 $\hat{\Sigma}$ on the fibre $P_x(\lambda_{\mathrm{UV}})\mathcal{H}_{\mathrm{total}}$, the maps

$$v \longmapsto \Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}}(g;x;v), \qquad v \longmapsto \Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}}(g;x;v)$$

are continuous and bounded; moreover, *small band deformations* $(\lambda_{\mathrm{UV}}, \ell) \mapsto (\lambda'_{\mathrm{UV}}, \ell')$ induce $\mathcal{O}(\varepsilon)$ variations controlled by an effective cutoff $\Lambda_{\mathrm{eff}}(x, x'; \varepsilon)$. This is summarized succinctly as $\mathcal{O}(\varepsilon)$-stability of the contrasts under small band moves (cf. Definitions 9.22, 9.23 and 9.166, eqs. (9.5) to (9.7) and (9.11), Lemma 9.27, and Remark 9.82).

Quadrant logic before realization: the Σ–aware predicate Before ℓ_P, the physical QI–QIV logic is *mirrored* by a *pre-physical, Σ–aware quadrant predicate* at each point x, using the two Σ–contrasts $\Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}}(g;x)$ and $\Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}}(g;x)$ with a small tolerance ε:

$$\textbf{QI}: \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}} < \varepsilon, \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}} < \varepsilon, \quad \textbf{QII}: \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}} < \varepsilon, \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}} > \varepsilon,$$

$$\textbf{QIII}: \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}} > \varepsilon, \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}} < \varepsilon, \quad \textbf{QIV}: \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{law}} > \varepsilon, \ \Delta^{\mathrm{pre},\Sigma}_{\mathrm{state}} > \varepsilon,$$

with the explicit note that this *mirrors* the physical quadrant logic in $H^0(\hat{Q}_{\mathrm{BRST}})$ (cf. Definitions 9.23 and 9.28 and Section 9.11). Interpretability is aided by a *triadic attribution*: decisions made from Σ–contrasts decompose into contributions from *coherence*, *vacuum*, and *spectral shear* (the "triadic" split of the chronogeometry), and this attribution respects gauge invariance and band locality (cf. Propositions 9.25 and 9.29 and eq. (9.195)).

BRST hygiene of PSR diagnostics and Σ-causality. Band tags $\mathfrak{B}_{\lambda_{\mathrm{UV}},\ell}$ built from BRST-closed operators $P_x(\lambda_{\mathrm{UV}})$ and $K_{\mathrm{IR}}^{(\ell)}$ (cf. Definitions 6.278, 6.280 and 6.282) descend to cohomology and render PSR diagnostics valid inputs for realization on $\mathcal{H}_{\mathrm{phys}} = H^0(\hat{Q}_{\mathrm{BRST}})$ (cf. Proposition 7.16). In particular, the band-prepared Ward/Nielsen structure implies gauge-parameter independence for physical readouts once realized (cf. eqs. (7.201) and (7.209)). Replacing separate "metric+temporal" data by the realized chronogeometric carrier $\bar{\Sigma}$ (cf. Definitions 5.25 and 5.26), the quadratic operators $\mathcal{K}_\Psi(\bar{\Sigma})$ and the physical retarded kernels $G^{\mathrm{R}}_{\bullet;\mathrm{phys}}$ (cf. Definitions 6.274 and 7.15) are Σ-*causal*: their supports respect the causal cones determined by $\bar{\Sigma}$, while the cohomological and Ward/Nielsen overlays remain unchanged (cf. Definitions 5.77 and 6.7 and Section 5.4).

Interpretation across regimes. The BRST-closed band preparation and the descent-to-cohomology statement concern the PSR (pre-physical) stage, ensuring that operator-level diagnostics are admissible and stable prior to realization. The Σ-causal retarded kernels $G^{\mathrm{R}}_{\bullet;\mathrm{phys}}$ and their gauge-independent readouts pertain to the realized/physical diagnostic realized reference configuration, where $\bar{\Sigma}$ controls causal support and Ward/Nielsen identities continue to hold verbatim (cf. eqs. (7.201) and (7.209)).

Stability & SVD recovery. The entire Σ-weighted extraction at PSR level is stable under band deformations: eigenvalues, normalizations, and operator solutions vary continuously with $(\lambda_{\mathrm{UV}}, \ell)$. In the correlator-only regime or when $\hat{\Sigma} \propto \mathbb{I}$, the generalized Σ-weighted eigenproblems reduce to the usual SVD with familiar block factorizations (cf. Section 6.1.1). On a certified plateau $\mathfrak{P}$ (cf. Definitions 7.47 and 9.58 and Section 6.12.4), these stability properties carry over to realized/physical objects by the Σ-realization step, preserving the spectral identifications and normalization equivalences established at the operator level.

From Σ-PSR to realized physics. *Plateau & Σ-realization.* Upon certifying a plateau $\mathfrak{P}$ (cf. Definitions 6.300, 7.47 and 9.58 and Section 6.12.4), apply the Σ-realization map $\mathcal{U}_\Sigma$ to obtain the physical chronogeometry

$$\bar{\Sigma}_{\mu\nu} \;=\; \left\langle \mathcal{U}_\Sigma[\hat{\Sigma}_{\mu\nu}] \right\rangle,$$

with $\hat{\Sigma}_{\mu\nu} = \hat{g}_{\mu\nu} + \hat{t}_{\mu\nu}$ (cf. Definitions 5.25 and 5.26). Construct the Σ-*causal* retarded kernels $G^{\mathrm{R}}_{\Phi\Phi;\mathrm{phys}}$ and $G^{\mathrm{R}}_{\Theta\Theta;\mathrm{phys}}$, whose supports respect the cones determined by $\bar{\Sigma}$ (cf. Definitions 5.77 and 6.7 and Section 5.4); cohomological inversion and Ward/Nielsen overlays remain as in the band-prepared formulation (cf. Definitions 6.274 and 7.15, Proposition 7.16, and eqs. (7.201) and (7.209)).

Carry-over of Nielsen safety. On a certified $\mathfrak{P}$, the realized $\bar{\Sigma}$ is gauge-parameter independent; therefore any quantity proven Nielsen-safe in the band analysis retains this property when rewritten as a functional of $\bar{\Sigma}$ (the wording "triad → $\bar{\Sigma}$" changes, not the conclusion) (cf. Proposition 7.208 and eqs. (7.20) and (7.21)).

Normalization equivalence. Particle-level criteria—pole locations, residues, positivity, and Nielsen safety—are invariant under the switch to Σ-inner products; Σ-based normalizations are equivalent to their triadic counterparts up to a positive bounded reweighting induced by $\hat{\Sigma}$ (cf. Definitions 5.25 and 5.26 and eq. (7.12)).

Poles/residues immovable under gauge scans or ζ-exact redefinitions. On $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$, BRST-exact insertions vanish (cf. Principle 6.1); with $\bar{\Sigma}$ Nielsen-flat on $\mathfrak{P}$, the realized poles and residues of the Σ-causal kernels cannot be shifted by gauge-parameter scans or by exact (ζ-exact) redefinitions (cf. eqs. (7.20), (7.21) and (7.209)).

Realization and physical reading (after ℓ_P) Once $\ell \geq \ell_P$, the chapter *projects to the physical sector* and evaluates *physical, channelized visibilities* $\left(\Lambda_{\text{law}}, \Lambda_{\text{state}}\right)$ on certified plateaux $\mathfrak{P}$; SynTh and parasymmetric meters apply here and remain BRST-safe. This is where the *quadrant logic becomes physical* (poles/residues on H^0) and where the Chapter 8 plateau geometry and Nielsen safety can be used *verbatim* (cf. Sections 9.5 and 9.16, Proposition 9.281, Definition 9.63, and Remark 9.82).

Chapter 9 welds a Σ–aware, band-local chronogeometric layer to the existing band/BRST framework. Before ℓ_P it supplies *operator-level, expectation-free* meters (stable under band moves) and a *pre-physical quadrant predicate* that mirrors the physical one. At and above ℓ_P it *hands off* to the Chapter 8 logic: certify $\mathfrak{P}$, project to $H^0(\hat{Q}_{\text{BRST}})$, evaluate $\left(\Lambda_{\text{law}}, \Lambda_{\text{state}}\right)$, and read spectra via poles/residues—now with Σ-built structures ensuring *gauge invariance*, *band locality*, and *robustness* of the decision flow (cf. Definition 9.60 and eqs. (9.26) and (9.27)).

High-level intuition I. At a high level, the Σ-centric picture turns the construction into a single geometric dial that simultaneously captures "shape" (amplitude curvature $\hat{g}$) and "flow" (temporal phase $\hat{t}$) through $\hat{\Sigma} = \hat{g} + \hat{t}$ (cf. Definitions 5.25 and 5.26). In the pre-physical PSR stage ($\ell < \ell_P$), diagnostics live at the operator level: band taggers prepare a clean arena (cf. Definitions 6.278 and 6.280), BRST/Nielsen hygiene ensures descent to cohomology and gauge-stable algebra (cf. Principle 6.1 and Propositions 6.214 and 7.16), and Σ-weighted contrasts select broken directions and principal modes via generalized eigenproblems within the unified correlator stack (cf. Section 6.1.1). The purpose at this stage is to produce eligibility data that are robust under UV/IR deformations, not to make physical claims. Realization begins only on a certified plateau $\mathfrak{P}$ (cf. Definition 9.58): the Σ-realization map $\mathcal{U}_\Sigma$ yields the diagnostic realized reference configuration geometry $\bar{\Sigma}$ (cf. Definition 5.26), retarded kernels become explicitly Σ-causal with support constrained by the $\bar{\Sigma}$-cones (cf. Definitions 5.77 and 6.7 and Section 5.4), and gauge-parameter independence proven on the band protects the ensuing physical readouts (cf. eqs. (7.201) and (7.209) and Definition 6.274).

High-level intuition II. Once realized, the picture is organised by typed subspaces and typed meters on H^0. Projectors $\Pi_S^{[\chi]}$ carve $\mathcal{H}_{\text{phys}}$ into operational slices aligned with the field packaging—e.g., Gaiamiti TT/Tr and Tantrakyma T/L, helicities, and the torsional Chrono–Kymon channel (cf. Sections 6.1 and 8.2 and Definition 6.141). Witnesses then evaluate law-symmetry and state-coherence where they matter (cf. Section 8.1 and Definition 6.275), and the resulting visibilities feed the canonical quadrant logic—QI (unbroken), QII (SSB with NG poles), QIII (emergent symmetry that heals with scale), QIV (explicit breaking with pNG behaviour) (cf. Definition 7.685, Theorems 6.231 and 7.630, and Corollary 7.631). Labels such as spin, helicity, and polarisation are fixed operationally by typed behaviour rather than by names (cf. Section 6.1). Because poles and residues are isolated with Riesz projectors on $\mathfrak{P}$ and read on H^0, they inherit Nielsen safety and BRST consistency

(cf. eqs. (7.20), (7.21), (7.209) and (7.438)): intuitively, PSR is the disciplined rehearsal that isolates the score, while realization is the performance on a certified stage where the acoustics ($\bar{\Sigma}$) and the microphones (typed witnesses) make the physical notes—poles, residues, visibilities—audible and robust.

Typed subspaces, typed meters, and typed quadrants on H^0. *Typed projectors & menus.* On the instrumented diagnostic realized reference configuration, introduce BRST-closed, cone-preserving typed projectors $\Pi_S^{[\chi]}$ that select subspaces compatible with the $\bar{\Sigma}$-causal cones (cf. Principle 6.1 and Definitions 5.77 and 6.7). The allowed menus match the field packaging (cf. Sections 6.1 and 6.4): **Gaiamiti** ($\Phi\Phi$) with TT (spin-2) and Tr (spin-0) types, and optional vectorial admixtures under a $\bar{\Sigma}$-preferred foliation; **Tantrakyma** ($\Theta\Theta$) with T/L types, helicities $\lambda = \pm$ where chiral frames exist, and a torsional/time-like *Chrono–Kymon* channel (spin-1 precursor) treated as its own type (cf. Definitions 5.77 and 6.141). These typed subspaces are constructed to be BRST-closed and thus descend to cohomology on $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$ without ambiguity (cf. Proposition 7.16).

Typed witnesses (SynTh) and drivers. Inserting $\Pi_S^{[\chi]}$ into the SynTh meters (cf. Sections 8.2 and 8.2.1) yields the typed witness $\mathbf{W}_{[\chi]}^{[S]}$, with representative readouts

$$v_{[\chi]}^{(L)} = \left|\text{Res}_{k^2=0}\ \Delta_{\Theta\Theta}^{[\chi]}(k)\right|, \quad v_{[\chi]}^{(S)} = \left\|\Delta_{\Theta\Theta}^{[\chi]}\big(t\to\infty;\,\mathbf{x}=0\big)\right\|_{H^0},$$
$$v_{[\chi]}^{(LS)} = \text{typed cross-channel gain.}$$

evaluated on $\mathcal{H}_{\text{phys}}$ inside a certified plateau $\mathfrak{P}$ and therefore Nielsen-flat by construction (cf. Definitions 6.275 and 9.58, Section 8.1, Proposition 7.208, and eqs. (7.20) and (7.438)).

Typed quadrant predicate & ledger. The canonical typed quadrant $\text{Quad}^{[S,\chi]} \in \{\text{QI}, \text{QII}, \text{QIII}, \text{QIV}\}$ is determined from the typed meters together with healing indicators, reusing the decision rule and overlays developed earlier (cf. Definition 7.685, Theorem 6.231, and Corollary 6.232). Existence, gauge/Nielsen safety, and uniqueness up to $\mathcal{O}(\varepsilon_{\mathfrak{P}})$ follow on $\mathfrak{P}$, yielding a well-defined mapping $(\mathfrak{P}; S, [\chi]) \mapsto \mathbf{L}^{[S,\chi]}$ for the typed ledger (cf. Sections 6.12.4 and 6.12.7 and Definitions 6.300 and 7.47).

Operational fixing of labels. Once $\mathbf{L}^{[S,\chi]}$ is populated, spin/helicity/polarization labels are fixed *operationally* by the chosen $[\chi]$ (independently of particle nomenclature); symmetry-breaking terminology (e.g., "graviton," "Higgs/NG/pNG") is applied only afterwards, consistent with the typed identification and the cohomological/causal structure (cf. Section 6.1 and Definition 5.77).

Typed NG/pNG semantics. If $\text{Quad}^{[S,\chi]} = \text{QII}$, the correlational channel exhibits an exact NG pole with positive residue on H^0 (cf. eqs. (7.12) and (7.438)); if QIV, it exhibits a pseudo-NG band with a GMOR slope certified on $\mathfrak{P}$ (cf. Theorem 7.630 and Corollary 7.631). The remaining cases follow the standard quadrant semantics: QI fully symmetric and QIII without IR NG/pNG realization (cf. Definition 7.685).

Gaiamiti sector (the ($\Phi\Phi$)–block): physical realization. On a certified plateau $\mathfrak{P}$ with readout on $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$ (cf. Definition 9.58), the Gaiamiti dynamics follow from expanding the action about the symmetric anchor and varying the tagged functional to solve

the Euler–Lagrange system

$$\frac{\delta S_\Phi}{\delta \Phi} = 0, \qquad D_\mu \text{ the appropriate (possibly internal) connection,}$$

as in Section 9.17.7 and eqs. (9.107) and (9.108). On an SSB background $\langle\Phi\rangle$, the law channel is exactly flat along the transverse–traceless (TT) tangents of the Gaiamiti manifold: these TT directions form the Goldstone manifold for global breaking in the $(\Phi\Phi)$ block, identifying a massless spin–2 *composite graviton* (cf. Proposition 9.243 and Section 9.17.5). In the two–point sector the TT correlator exhibits an NG pole at $k^2 = 0$ with positive residue,

$$\Delta^{\mathrm{TT}}_{\Phi\Phi}(k) \;=\; \frac{Z_{\mathrm{grav}}}{k^2 + i0^+} \;+\; \text{regular}, \qquad Z_{\mathrm{grav}} > 0,$$

encoded by the residue weights for the composite graviton (cf. Definition 9.265; positivity on $\mathcal{H}_{\mathrm{phys}}$ aligns with eq. (7.12)).

Radial/trace ("Gaiaton") mode is gapped. Orthogonal to the TT manifold, the radial/-trace direction ("Gaiaton") is governed by the Gaiamiti potential scale. The band–prepared Hessian yields a single scalar pole at $k^2 = m_A^2 > 0$ with no ghosts or tachyons on $\mathcal{H}_{\mathrm{phys}}$, captured by the typed radial mass operators in both global and gauged settings (cf. Definitions 9.250 and 9.259; see also Section 9.17.4).

Internal gauge BEH in the Gaiamiti block. If an internal gauge group acts on Φ with $D_\mu = \partial_\mu - ig\,A_\mu$, the SSB background $\langle\Phi\rangle$ induces a Brout–Englert–Higgs (BEH) mass matrix for the broken internal generators. The would–be longitudinal Goldstones are BRST–quartet and unphysical, leaving massive spin–1 vectors in the realized spectrum for broken directions, while unbroken generators remain massless (construction and mass statement in Section 9.17.4 and Proposition 9.257). Gauge–parameter independence of these masses and on–shell visibilities is ensured at realization by the Nielsen identity (cf. Theorem 9.351); explicit U(1) templates appear in Section 9.18.8.

Main Gaiamiti quanta.

- Massless spin–2 *graviton* (TT Goldstone of global SSB): Proposition 9.243 and Definition 9.265.
- Gapped scalar *Gaiaton* (radial/trace excitation): Definitions 9.250 and 9.259.
- *Massive internal vectors* ("mition") from BEH for broken internal generators; massless for unbroken ones: Section 9.17.4, Proposition 9.257, and Theorem 9.351.

BEH of the Gaiamiti (apeiron). We work on a certified plateau $\mathfrak{P}$ with physical readout on $\mathcal{H}_{\mathrm{phys}} = H^0(\hat{Q}_{\mathrm{BRST}})$ (cf. Definition 9.58). The Gaiamiti field Φ has potential $V(\Phi)$ and may transform under an internal gauge group G_{int} with generators T_I and connection $A_\mu = A_\mu^I T_I$.

The Σ-centric kinetic term uses the Diagnostic realized reference configuration tensor $\bar{\Sigma}_{\mu\nu}$ and the covariant derivative [112, 38]

$$D_\mu \Phi = \partial_\mu \Phi - ig\, A^I_\mu T_I \Phi,$$

so the relevant Lagrangian pieces read [38]

$$\mathcal{L}_{\Phi,\text{gauged}} = \tfrac{1}{2}\,\bar{\Sigma}^{\mu\nu}(D_\mu\Phi)^\dagger(D_\nu\Phi) - V(\Phi) - \tfrac{1}{4}\,\bar{\Sigma}^{\mu\alpha}\bar{\Sigma}^{\nu\beta}\,F^I_{\mu\nu}F^I_{\alpha\beta} \qquad F^I_{\mu\nu} = \partial_\mu A^I_\nu - \partial_\nu A^I_\mu + g\, f^I{}_{JK}\, A^J_\mu A^K_\nu.$$

Band instrumentation is BRST-closed and typed projectors commute with the setup [52, 117, 114]. The SSB background $\langle\Phi\rangle = v$ breaks $G_{\text{int}} \to H$ and simultaneously fixes the TT *Goldstone sheet* in the $(\Phi\Phi)$ block and the orthogonal *radial/trace* (Gaiaton) direction (cf. Sections 9.17.4 and 9.17.7, eqs. (9.107) and (9.108), Proposition 9.243, and Definition 9.250); the BEH interpretation aligns with the standard gauge/Goldstone structure [38, 112].

Gauge–boson masses from $\langle\Phi\rangle$ (BEH matrix). Expanding $\Phi = v + \varphi$ in $\mathcal{L}_{\Phi,\text{gauged}}$, the covariant term yields a vacuum–algebraic quadratic piece in A_μ:

$$\mathcal{L}^{(A)}_{\text{mass}} = \tfrac{1}{2}\,\bar{\Sigma}^{\mu\nu}\,A^I_\mu (M^2)_{IJ} A^J_\nu, \qquad (M^2)_{IJ} := g^2\,\langle\, T_I v,\ T_J v\,\rangle_\Phi \quad (\geq 0).$$

Equivalently, in representation–matrix form [38, 112],

$$(M^2)_{IJ} = g^2\, v^\dagger \{T_I T_J\}_{\text{sym}} v, \qquad \{T_I T_J\}_{\text{sym}} := \tfrac{1}{2}\,(T_I T_J + T_J T_I).$$

Each *broken* generator $X_a \in \mathfrak{g}/\mathfrak{h}$ contributes a non–negative direction in $(M^2)_{IJ}$, while *unbroken* generators $H_\alpha \in \mathfrak{h}$ satisfy $T_{H_\alpha} v = 0$ and give *massless* vectors (cf. Section 9.17.4 and Proposition 9.257). Nielsen safety on $\mathfrak{P}$ ensures gauge–parameter independence [120, 121, 114] (cf. Theorem 9.351):

$$\frac{\partial}{\partial\xi}\,\det\!\Big[q^2\bar{\Sigma}^{\mu\nu}\delta^{IJ} - (M^2)^{IJ}\bar{\Sigma}^{\mu\nu}\Big] = 0 \implies \partial_\xi\, m^2_{\text{vector},\lambda} = 0 \quad \text{on } \mathfrak{P}.$$

Goldstones and BRST quartet decoupling. Decompose the apeiron fluctuation by the chapter's typed projectors in $(\Phi\Phi)$:

$$\varphi = \varphi_\parallel + \varphi_{\text{rad}}, \qquad \varphi_\parallel = \sum_I \alpha^I\, T_I v,$$

so $\varphi_\parallel$ spans the tangent (would–be Goldstone) directions and φ_{rad} the radial/trace (Gaiaton). The linearized equations identify $\varphi_\parallel$ as gauge directions; in BRST quantization they form *quartets* and are absent in $\mathcal{H}_{\text{phys}}$ [117, 52]. The mixing

$$g\,\bar{\Sigma}^{\mu\nu} A^I_\mu\,\langle T_I v,\ \partial_\nu\varphi\rangle_\Phi$$

is removed by gauge fixing/BRST completion, leaving the longitudinal modes unphysical while the transverse vector spectrum is governed by $(M^2)_{IJ}$ [38, 109] (cf. Section 9.17.4, Proposition 9.257, and Theorem 9.351).

Radial (trace) Gaiaton in the gauged theory. Orthogonal to the tangent sheet, the Gaiaton is the radial/trace amplitude mode. Its mass is fixed by the typed *radial mass operator*: globally by $\hat{\mathbb{M}}^{(\mathrm{rad})}_{\mathrm{glob}}$ and, in the gauged case, by the *apeiron radial mass operator (gauged)* $\hat{\mathbb{M}}^{(\mathrm{rad})}_{\mathrm{gauged}}$ (cf. Definitions 9.250 and 9.259). At quadratic order on $\mathfrak{P}$,

$$\mathcal{L}_{\mathrm{rad}} = \tfrac{1}{2}\,\bar{\Sigma}^{\mu\nu}\,\partial_\mu\varphi_{\mathrm{rad}}\partial_\nu\varphi_{\mathrm{rad}} - \tfrac{1}{2}\,m_A^2\,\varphi_{\mathrm{rad}}^2, \qquad m_A^2 = \langle\varphi_{\mathrm{rad}},\ \hat{\mathbb{M}}^{(\mathrm{rad})}_{\mathrm{gauged}}\ \varphi_{\mathrm{rad}}\rangle_\Phi > 0,$$

so the realized two–point function exhibits a single scalar pole at $k^2 = m_A^2$ with no ghost-s/tachyons on $\mathcal{H}_{\mathrm{phys}}$ [38, 52, 117]. On–shell gauge–parameter independence (Nielsen safety) follows from the Nielsen identities in the BFM setting [120, 121, 114] (cf. Theorem 9.351).

Typed/Σ–causal structure and decoupling from the graviton. The Gaiamiti BEH reorganizes the *internal spin–1* sector (vectors A_μ) and the *spin–0* radial sector; it does *not* induce a mass for the spin–2 graviton. The spin–2 carrier is the York–projected TT metric fluctuation, for which the TT block remains massless with positive residue (composite TT Goldstone) and is insulated from vector BEH [43, 44, 45, 38, 112]; observationally, bounds are consistent with a (nearly) massless graviton [122]. All propagators and vertices are $\bar{\Sigma}$–causal, and on $\mathfrak{P}$ all on–shell data (poles, residues, masses) are Nielsen–safe [120, 121, 114] (cf. Theorem 9.351).

Broken internal directions acquire vector masses from $(M^2)_{IJ} = g^2\langle T_I v, T_J v\rangle_\Phi$, while unbroken ones remain massless; would–be Goldstones decouple as BRST quartets [38, 52, 117] (cf. Section 9.17.4 and Proposition 9.257). The Gaiaton is a single gapped scalar with $k^2 = m_A^2 > 0$, determined by the typed radial operator (cf. Definitions 9.250 and 9.259 and Section 9.17.4). The TT graviton remains massless (TT Goldstone of global SSB in $(\Phi\Phi)$); there is no BEH leakage into spin–2 [113, 109]. All on–shell statements are Nielsen–safe on $\mathfrak{P}$ [120, 121, 114] (cf. Theorem 9.351).

The Tantrakyma sector (the $(\Theta\Theta)$–block): physical realization. Work on a certified plateau $\mathfrak{P}$ with readout on $\mathcal{H}_{\mathrm{phys}} = H^0(\hat{Q}_{\mathrm{BRST}})$ (cf. Definition 9.58). The sector is instrumented by BRST–closed typed projectors and a permitted kinematics that decompose Θ into operational subspaces (set–up and bookkeeping in Sections 9.15.3 and 9.17.11, projectors in Definition 9.295). Linearising the band Hessian about the SSB background $\langle\Theta\rangle$ yields the typed Hessian and the corresponding typed linear–response system,

$$\frac{\delta S_\Theta}{\delta\Theta} = 0 \quad (\text{in each type})\,,$$

whose spectra are then read physically on $\mathfrak{P}$ (cf. eqs. (9.124) and (9.125)). These diagnostics are evaluated with the same cohomological/Nielsen hygiene as elsewhere, now within the $(\Theta\Theta)$ block and its typed slices.

Global SSB $\to$ scalar NG (or multiplet) in the Θ directions. Broken global generators in the Θ directions yield Nambu–Goldstone scalar(s) that are gapless in the large–volume limit, while unbroken generators leave modes massless or gapped according to the typed pattern selected by Definition 9.295 [32, 112, 38]. The existence and reading of these modes follow from the typed Hessian and linear–response equations (cf. eqs. (9.124) and (9.125)).

Internal gauge BEH in the Tantrakyma block. If Θ carries an internal gauge action, broken internal directions generate a Brout–Englert–Higgs (BEH) mass matrix for spin–1 vectors; the associated Tantrakyma would–be Goldstones are removed from the physical spectrum by quartet decoupling, while the unbroken internal subgroup yields massless vectors (the "tantron") [38, 112, 52, 117] (cf. Definition 9.345 and Proposition 9.347). Gauge–parameter independence of these on–shell masses and readouts at realization is ensured by the Nielsen identity [120, 121, 114] (cf. Theorem 9.351).

Pseudo–NG (pNG) when mild explicit breaking is present. With small explicit terms in the Θ potential, the would–be NG acquires a small mass squared determined by the *typed* mass operator extracted from the potential; explicit formulae and parameter relations are given in eqs. (9.175), (9.190) and (9.193) [112, 32].

Main Tantrakyma quanta (realized on $\mathfrak{P}$).

- *NG scalar(s)* of global SSB in the Θ directions (gapless in the large–volume limit): eqs. (9.124) and (9.125).
- *Massive internal vectors* from BEH for broken internal directions; *massless internal vectors* ("tantron") for unbroken ones: Definition 9.345, Proposition 9.347, and Theorem 9.351.
- *Radial Tantrakyma scalar* (Higgs–like amplitude mode) gapped; light pNG in the presence of small explicit breaking: eqs. (9.175) and (9.193).

BEH of the Tantrakyma (kymon). Work on a certified plateau $\mathfrak{P}$ and read on $\mathcal{H}_{\rm phys} = H^0(\hat{Q}_{\rm BRST})$. The Tantrakyma field Θ is instrumented by BRST–closed *typed projectors* and permitted kinematics that decompose Θ into operational subspaces [52, 117, 114] (set–up in Sections 9.15.3 and 9.17.11, projectors in Definition 9.295). When Θ transforms under an internal gauge group $G_{\rm int}$ with generators T_I and connection $A_\mu = A^I_\mu T_I$, the Σ–centric realized kinetic term and potential are [38, 112]

$$D_\mu\Theta = \partial_\mu\Theta - ig\,A^I_\mu T_I\Theta, \qquad \mathcal{L}_{\Theta,\text{gauged}} = \tfrac{1}{2}\,\bar{\Sigma}^{\mu\nu}(D_\mu\Theta)^\dagger(D_\nu\Theta) - V(\Theta) \;-\; \tfrac{1}{4}\,\bar{\Sigma}^{\mu\alpha}\bar{\Sigma}^{\nu\beta}F^I_{\mu\nu}F^I_{\alpha\beta},$$

with $F^I_{\mu\nu} = \partial_\mu A^I_\nu - \partial_\nu A^I_\mu + g f^I{}_{JK} A^J_\mu A^K_\nu$ [38]. An SSB background $\langle\Theta\rangle = w$ breaks $G_{\rm int} \to H$ and sets the typed decomposition used to read the spectrum via the *typed Hessian* and linear response (cf. eqs. (9.124) and (9.125)) [112, 38].

Vector masses from $\langle\Theta\rangle$ (Tantrakyma BEH matrix). Expanding $\Theta = w + \vartheta$ in $\mathcal{L}_{\Theta,\text{gauged}}$, the covariant term yields a vacuum–algebraic quadratic piece in the gauge fields:

$$\mathcal{L}^{(A)}_{\rm mass} = \tfrac{1}{2}\,\bar{\Sigma}^{\mu\nu}\,A^I_\mu(M^2_V)_{IJ}A^J_\nu, \qquad (M^2_V)_{IJ} := g^2\,\langle\, T_I w,\; T_J w\,\rangle_\Theta \;\; (\geq 0).$$

Equivalently, in representation–matrix form [38, 112],

$$(M^2_V)_{IJ} = g^2\,w^\dagger\{T_IT_J\}_{\rm sym}w, \qquad \{T_IT_J\}_{\rm sym} := \tfrac{1}{2}\,(T_IT_J + T_JT_I).$$

Broken internal directions $X_a \in \mathfrak{g}/\mathfrak{h}$ give strictly non–negative directions in $(M_V^2)_{IJ}$ and hence *massive* spin–1 vectors, whereas unbroken $H_\alpha \in \mathfrak{h}$ satisfy $T_{H_\alpha} w = 0$ and yield *massless* vectors ("tantrons") (cf. Definition 9.345 and Proposition 9.347). On $\mathfrak{P}$, the on–shell vector masses are *Nielsen–safe* [120, 121, 114]:

$$\frac{\partial\, M_{V,\lambda}^2}{\partial \xi} = 0 \quad \text{for all eigenmodes } \lambda, \qquad \text{(cf. Theorem 9.351)}.$$

Goldstones and BRST quartet decoupling. Use the typed projectors of Definition 9.295 to split the fluctuation into *tangent* (would–be Goldstone) and *radial* pieces,

$$\vartheta = \vartheta_{\parallel} + \vartheta_{\mathrm{rad}}, \qquad \vartheta_{\parallel} = \sum_I \beta^I\, T_I w.$$

The mixing term $g\,\bar{\Sigma}^{\mu\nu} A_\mu^I \langle T_I w,\ \partial_\nu \vartheta\rangle_\Theta$ is removed by gauge fixing/BRST completion [52, 117]; the $\vartheta_{\parallel}$ modes become *unphysical* (quartets) and do not appear in $\mathcal{H}_{\mathrm{phys}}$, while the transverse vector spectrum is governed by $(M_V^2)_{IJ}$ as above [38, 112] (cf. Definition 9.345, Proposition 9.347, and Theorem 9.351).

Radial amplitude and pseudo–NG masses. Orthogonal to the tangent sheet, the *radial Tantrakyma* (Higgs–like amplitude) mode is gapped, with its mass read from the typed Hessian of the potential in the appropriate projector slice (cf. eqs. (9.124) and (9.125)) [38, 112]. When *mild explicit breaking* is present in $V(\Theta)$, the would–be NG scalars acquire *pseudo–NG* (pNG) masses determined by a typed mass operator extracted from the potential, with explicit formulae given in

$$m^2_{\mathrm{pNG},[\chi]} = \lambda\Big(\mathbb{M}^{[\chi]}_{\mathrm{typed}}\Big), \qquad \text{cf. } \textit{eqs.}\ (9.175), (9.190) \textit{and}\ (9.193),$$

and these masses inherit gauge–parameter independence at realization (Nielsen safety) [120, 121, 114] (Theorem 9.351).

Typed/Σ–causal structure and spectrum summary. All readouts are taken in the typed slices fixed by $\Pi_\Theta^{[\chi]}$ and propagate with Σ–causal support; the spectrum is therefore operationally defined and BRST/Nielsen–clean on $\mathfrak{P}$ [52, 114]. In summary: broken internal directions in the Tantrakyma sector generate *massive spin–1 vectors* via the BEH matrix $(M_V^2)_{IJ}$, unbroken directions yield *massless* tantrons [38, 112] (cf. Definition 9.345 and Proposition 9.347); the *radial Tantrakyma* amplitude mode is *gapped*; and with small explicit breaking the *NG scalars* become *pNG* with masses fixed by the *typed* mass operator [112, 32] (cf. eqs. (9.175), (9.190) and (9.193)). All on–shell masses and residues are *Nielsen–safe* at realization [120, 121, 114] (Theorem 9.351).

Joint reading and provenance

- **Quadrant logic.** The Gaiamiti TT block realises a QI/QIII–like law reading in the TT channel (exact or IR–healing) with a gapped trace, while the Tantrakyma block separates cleanly into state versus law channels per the Chapter 8/9 witness pair: global

SSB appears in the state channel (NG/pNG), internal BEH in the gauge sector. All readouts are plateau–certified and Nielsen–safe in the realised regime; cf. Corollary 9.139 and Theorem 9.351.

- **Spectral hygiene.** Two–point functions in both blocks exhibit positive spectral weights in $\mathcal{H}_{\text{phys}}$; pole/residue data are gauge–parameter independent within the audit window (Nielsen safety), and mixing with unphysical sectors is removed by quartet decoupling (cf. Definition 9.265 and Theorem 9.351).

In short.

- **Gaiamiti**: global SSB with TT Goldstone identified as the composite graviton (Proposition 9.243), a gapped radial mode (Definitions 9.250 and 9.259), and, when internally gauged, BEH–massive vectors (Section 9.17.4 and Proposition 9.257).
- **Tantrakyma**: global SSB with NG scalar(s) (or light pNG if small explicit breaking is present), a gapped radial mode, and—under internal gauging—BEH–massive vectors for the broken subgroup (massless for the unbroken one) (eqs. (9.124) and (9.175), Definition 9.345, Proposition 9.347, and Theorem 9.351).

Here, Chapter 9's realized spectrum is organised by the certified plateau $\mathfrak{P}$ and the physical cohomology $\mathcal{H}_{\text{phys}} = H^0(\hat{Q}_{\text{BRST}})$, so every on-shell statement inherits BRST/Nielsen protection and Σ-causality [114, 52, 117, 120, 121, 112]. In the *Gaiamiti* ($\Phi\Phi$) block, an SSB background $\langle\Phi\rangle$ renders the law channel exactly flat along the transverse–traceless tangents of the Gaiamiti manifold; these TT directions are the Goldstone manifold and realize a *massless spin–2 composite graviton* [43, 44, 45, 122]. In the two-point sector this appears as an NG pole at $k^2 = 0$ with positive residue, read as a genuine, positivity-respecting excitation on H^0 (cf. Proposition 9.243, Definition 9.265, and eq. (7.12)). Orthogonal to TT lies the *radial/trace ("Gaiaton")* amplitude mode, whose scale is set by the Gaiamiti potential; on the band-prepared Hessian it is *gapped* with a single scalar pole at $k^2 = m_A^2 > 0$ and no ghosts/tachyons on $\mathcal{H}_{\text{phys}}$ [38, 52, 112] (cf. Definitions 9.250 and 9.259 and Section 9.17.4). If an internal gauge symmetry acts on Φ, the realized picture includes a Brout–Englert–Higgs mechanism: broken internal generators yield *massive spin–1 vectors* (the "mition"), with the would-be Goldstones removed by the quartet mechanism, while unbroken generators remain *massless*; masses and on-shell visibilities are Nielsen-safe on $\mathfrak{P}$ [38, 52, 117, 120, 121, 114] (cf. Sections 9.17.4 and 9.18.8, Proposition 9.257, and Theorem 9.351).

Complementarily, the *Tantrakyma* ($\Theta\Theta$) block is the "matter-like" half. BRST-closed typed projectors and permitted kinematics decompose Θ into operational subspaces; linearising the typed Hessian about $\langle\Theta\rangle$ furnishes the typed linear-response system whose spectra are read physically on $\mathfrak{P}$ [52, 117] (cf. Sections 9.15.3 and 9.17.11, Definition 9.295, and eqs. (9.124) and (9.125)). Broken global generators along Θ produce *Nambu–Goldstone scalar(s)*, gapless in the large-volume limit, while unbroken directions remain massless or acquire a gap according to type [32, 112, 38]. A *radial (Higgs-like) amplitude mode* is generically gapped, setting the intrinsic scale of the sector [38]. With an internal gauge action on Θ, the typed structure cleanly realizes *BEH*: broken directions give *massive spin–1 vectors*, the associated would-be Tantrakyma Goldstones decouple as quartets, and the unbroken subgroup

yields *massless "tantrons"*; on-shell masses and residues are again Nielsen-safe at realization [38, 52, 117, 120, 121, 114] (cf. Definition 9.345, Proposition 9.347, and Theorem 9.351). Small explicit breakings in the Θ potential bend the NG story into *pseudo–NG (pNG)* behaviour with parametrically light masses fixed by a typed mass operator [112, 32] (cf. eqs. (9.175), (9.190) and (9.193)).

Taken together, Chapter 9's conclusion is operational and robust: on a certified $\mathfrak{P}$, the *geometry-generating* Gaiamiti block contributes a *gapless TT Goldstone (graviton)* and a *gapped radial Gaiaton*, plus *BEH-driven vectors* if gauged; the *matter-like* Tantrakyma block contributes *NG scalar(s)* aligned with its broken directions, a *gapped radial amplitude mode*, *massive* (broken) and *massless* (unbroken) internal vectors when gauged, and controlled *pNG* masses under mild explicit breaking. Because all readouts live on H^0 and respect the band/Nielsen stack, pole locations, residues, and masses are *gauge-parameter independent* and Σ-causal—delivering a physically stable, typed ledger of the realized spectrum in the Fourfold framework [114, 52, 120, 121, 38, 112, 122, 32].

Chapter 10: The Weave of Geometry and Matter

Chapter 10 fixes the chronogeometric realized weave configuration $(\bar{\Sigma}, \mathcal{I}^{[\mathscr{S}]})$ and explains how observable spin–2 content is cleanly isolated from temporal/coherence dynamics by the weave's TT projector. The centerpiece is the τ–kairos sector—defined as $\hat{\tau}_{\mu\nu} := \delta\hat{t}_{\mu\nu}$ and made *TT–null* by construction—whose typed/triad pipeline extracts scalar, pseudoscalar, and Chrono–Kymon (CK) vector registers from the geometric $\Phi\Phi$ block, promotes them through meters, and stamps T–L–O onsets without ever polluting the TT graviton readout. The chapter then integrates (i) the bi-local interaction kernel that preserves TT closure at the level of variations, (ii) the Goldstone interpretation of the graviton, and (iii) species-resolved whitening of operator eigen-operator pairs, before distinguishing the *connection* ledger—where the mition and tantron live—from τ's temporal ledger. What follows is a cohesive, equation-forward summary that weaves these strands into a single narrative consistent with Chapter 11's typed/triad formalism.

The τ–kairos sector, its typed/triad weave, and the connection quanta

Definition and TT–nullity. The temporal/coherence channel of chronogeometry is the *τ–kairos* sector,

$$\hat{\tau}_{\mu\nu} := \delta\hat{t}_{\mu\nu}, \qquad \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\hat{\tau}_{\mu\nu} = 0,$$

so τ is *TT–null* by construction. Equivalently, $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\Pi^{[\chi]} = 0$ for any non-TT type $[\chi]$ admitted by the weave (Definition 10.162 and Lemma 10.17). This structural TT–nullity guarantees that the observable spin-2 graviton lives purely in the metric TT channel and cannot be contaminated by temporal/coherence fluctuations.

Bimodal–triadic organization and typed decomposition. Chronogeometric two-point functions are organized bimodally (metric $\leftrightarrow$ temporal) and refined by triad provenance

$a \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\}$. Fixing the channel operators

$$\hat{h}_{\mu\nu} := \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\, \delta\hat{g}_{\mu\nu}, \qquad \hat{\tau}_{\mu\nu} := \delta\hat{t}_{\mu\nu},$$

with $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\hat{\tau}_{\mu\nu} = 0$, Chapter 11 resolves the τ tensor into scalar/pseudoscalar images and vector Chrono–Kymon (CK) helicities:

$$\boxed{\hat{\tau}_{\mu\nu} \;=\; S^{(b)}_{\mu\nu}[\hat{\varphi}_b] \;\oplus\; S^{(L)}_{\mu\nu}[\hat{\varphi}_L] \;\oplus\; \tilde{S}^{(p)}_{\mu\nu}[\tilde{\varphi}] \;\oplus\; \sum_{\lambda=\pm} A^{(\lambda)}_{\mu\nu}\Big[\hat{K}^{(\tau)}_{\lambda}\Big], \qquad \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\hat{\tau}_{\mu\nu} = 0.} \tag{4}$$

Here $S^{(b)}, S^{(L)}, \tilde{S}^{(p)}$ encode the scalar/pseudoscalar register, and $A^{(\pm)}$ carry the CK vector helicities (Definition 10.4 and Lemma 10.17). The CK register admits the gauge-covariant field-strength representative

$$\hat{\mathcal{F}}^{(\tau)}_{\mu\nu} = 2\,\bar{\nabla}_{[\mu}\hat{K}^{(\tau)}_{\nu]},$$

fixing the notation used by the typed projectors (Definition 10.57). The full fluctuation splits triadically as

$$\delta\hat{\Sigma}_{\mu\nu} = \delta\hat{\Sigma}^{(\mathrm{corr})}_{\mu\nu} + \delta\hat{\Sigma}^{(\mathrm{vac})}_{\mu\nu} + \delta\hat{\Sigma}^{(\mathrm{spec})}_{\mu\nu}, \qquad \hat{h}_{\mu\nu} = \sum_a \hat{h}^{(a)}_{\mu\nu}, \quad \hat{\tau}_{\mu\nu} = \sum_a \hat{\tau}^{(a)}_{\mu\nu}\ (\textit{Definition } 10.187).$$

Physical diagonal blocks and TT readout. The TT graviton propagator is the TT-projected metric-channel correlator,

$$G^{\mathrm{TT}}_{\mu\nu\rho\sigma} := \langle\Omega|\, T\{\hat{h}_{\mu\nu}\hat{h}_{\rho\sigma}\}\,|\Omega\rangle \;=\; \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\, G^{hh}\, \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]} \quad (\textit{eq. } (10.114)),$$

while the $\tau\tau$ block carries phase-flow/coherence physics and drives entanglement dynamics without mediating classical forces. Its typed entries $\chi \in \{\tau_S, \tau_A, K^{(\tau)}_{\mathrm{T}}, K^{(\tau)}_{\mathrm{L}}\}$ are TT-null and feed only non-TT T–L–O stamps (Definitions 10.4 and 10.13).

Off-diagonal mixing and TT closure. Off-diagonal correlators $\langle T\{\hat{h}, \hat{\tau}\}\rangle$ encode state-dependent metric–temporal conversion amplitudes but carry *no* spin-2 content. Projecting with $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}$ annihilates these blocks, so they cannot generate TT modes; equivalently the mixed correlator TT-projects to zero (TT-closure, Proposition 10.184). Thus τ produces *no* gravitational-wave polarizations (Corollary 10.177).

Typed matter channels, positivity, and cone–gating. Matter in the temporal/CK families is organized by typed projectors $\Pi^{[\chi]}$ with $\chi \in \{S^{(b)}, S^{(L)}, \tilde{S}^{(p)}, A^{(\pm)}\}$. On a certified plateau $\mathfrak{P}$, each admitted block

$$\hat{\mathbf{G}}^{[\Theta\to\Theta;\chi]}_{\Lambda;a} := \Pi^{(a)}\Pi^{[\chi]}\, \hat{\mathbf{G}}^{[\Theta\to\Theta]}_{\Lambda}\, \Pi^{[\chi]}\Pi^{(a)}$$

is a positive semidefinite covariance propagating within $\bar{\Sigma}$-cones (admission & hyperbolicity; Definition 10.206 and Corollary 10.207).

Bi-local interaction kernel and variational sources. Interaction between the geometric and kairotic sectors is bi-local and Hermitian,

$$\mathbf{U}_{\Lambda}^{[\Phi\leftrightarrow\Theta]}(x,x') := \hat{\mathbf{G}}_{\Lambda}^{[\Phi\to\Theta]}(x,x') + \Big(\hat{\mathbf{G}}_{\Lambda}^{[\Theta\to\Phi]}(x',x)\Big)^{\dagger},$$

triad-resolved into $\{\mathrm{spec},\mathrm{vac},\mathrm{corr}\}$ (*eqs.* (10.175)*and* (10.176)).

The bi-local interaction density reads

$$\mathcal{L}_{\mathrm{int}}(x,x') := \mathrm{Tr}\Big[(\delta\hat{\mathbf{\Phi}}(x))^{\dagger}\,\mathbf{U}_{\Lambda}^{[\Phi\leftrightarrow\Theta]}(x,x')\,\delta\tilde{\hat{\mathbf{\Theta}}}(x'\to x)\Big] \quad (Definition\ 10.222),$$

and first variations yield bi-local sources in the Euler–Lagrange equations while preserving TT closure upon projection (Proposition 10.224 and Remark 10.225).

T–L–O augmentation (ledger → meters → stamps). On a certified plateau $\mathfrak{P}$, the sector-execution functor $\mathscr{E}_{\bullet}$ augments $\mathbf{G}_{\Sigma}^{(2)}$ by: (i) typed admission and cone-gating; (ii) typed visibilities from correlator spectra; (iii) parasymmetric meters producing Onset windows $(r^{\star},t^{\star})$; (iv) stamping $\mathrm{TLO}^{[\chi]}$ with Location and Type consistent with Chapter 11's spin/polarization scope (Proposition 10.185). BRST/Nielsen safety and uniqueness follow from the weave propositions.

Apeiron (trace scalar) vs. graviton (TT) in $\Phi\Phi$. Within the geometric block, the trace-typed scalar channel is the **Apeiron**, defined by typed insertion/triad resolution; the *observable* graviton is the TT refinement of the same $\Phi\Phi$ block via $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}$. All non-TT types are strictly TT-null, ensuring clean spin-2 readout (eqs. (10.84) and (10.85)).

Typed sourcing of τ and particle content. Chapter 10 records τ sourcing without new primitives:

$$\hat{\tau}_{\mu\nu} = S_{\mu\nu}^{(b)}[\hat{\varphi}_b] \oplus S_{\mu\nu}^{(L)}[\hat{\varphi}_L] \oplus \tilde{S}_{\mu\nu}^{(p)}[\tilde{\varphi}] \oplus \sum_{\lambda=\pm} A_{\mu\nu}^{(\lambda)}[\hat{K}_{\lambda}^{(\tau)}],$$

with $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\hat{\tau}_{\mu\nu}=0$. Vector quanta in the temporal channel are CK modes; the TT graviton $\hat{\gamma}_{\mu\nu}$ is the Goldstone-tangential excitation of the metric channel (Remark 10.175).

Goldstone interpretation and induced dynamics. The operator mass $\mathcal{M}(x)$ arises from the Hessian of the Gaiamiti potential; flat directions yield Goldstones. The massless spin-2 graviton is the Goldstone of tangential Φ variations, projected to TT. The τ sector, while TT-null, may host scalar/vector modes with model-dependent masses. Linear response of the constitutive map determines how $\delta\hat{g}_{\mu\nu}$ and $\delta\hat{t}_{\mu\nu}$ inherit dynamics; the TT graviton is

$$\hat{h}_{\mu\nu} = \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\delta\hat{g}_{\mu\nu} \quad (eqs.\ (10.103)and\ (10.125)and\ Section\ 10.5).$$

Species resolution and operator-generalized eigen-operator pair whitening. Species-resolved TT projectors preserve the $\{\mathrm{spec},\mathrm{vac},\mathrm{corr}\}$ provenance. Species mixing is diagonalized via a $\bar{\Sigma}$-weighted operator-generalized eigen-operator pair eigenproblem $\mathcal{A}u=\lambda\,\mathcal{B}u$, with whitening $w=B^{-1/2}u$ so that $B^{-1/2}\mathcal{A}B^{-1/2}$ is self-adjoint in the reference inner product (Definitions 10.116 and 10.117).

Framework-level dynamics (closure and back-reaction). Varying the action w.r.t. Σ yields field equations where Tantrakyma contributes ordinary and coherence stress. Crucially, since $\Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\Pi^{[\chi]} = 0$, the spin-2 sector is dynamically closed: Tantrakyma/kymon effects sculpt $t_{\mu\nu}$ and its fluctuations, contribute to total stress, and leave the TT graviton sector untouched. T–L–O stamps log *when/where* temporal influences switch on (Section 10.17.4, Lemma 10.17, and Propositions 10.22 and 10.65).

Relation to Chapter 7 (backbone → readout). Chapter 10's $\Phi\Phi$ blocks and their TT/triad refinements are *typed projections* of the unified inter-modal correlator $\hat{\mathbf{G}}_\Lambda$ introduced in Chapter 7: one first fixes the realized weave configuration $(\bar{\Sigma}, \mathcal{I}^{[\mathscr{S}]})$ and then projects $\Phi\Phi \to$ triad $\to$ TT, ensuring compatibility with relational covariance and TT-nullity of non-TT types (Definitions 10.157 and 10.158 and eq. (10.83)).

TT isolation of the graviton and the $\Theta\Theta$ register. By TT isolation the graviton is

$$\hat{h}_{\mu\nu} = \Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\, \delta\hat{g}_{\mu\nu} = \Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\, \delta\hat{\Sigma}_{\mu\nu},$$

with τ annihilated by $\Pi^{[\mathrm{TT}]}$ (Lemma 10.172). Higgs/radial kymon content sits in the $\Theta\Theta$ block and interfaces with τ only via the shared typed/ledger pipeline (never by identification).

Where τ is *operational*. τ dominates in coherence-rich regimes—laboratory interferometry, early-universe epochs, near-horizon domains—where admissions/onsets are metered and TT purity is continuously witnessed by the T–L–O layer (Section 10.16).

Connection quanta: *mition* and *tantron*. A distinct strand concerns spin-1 excitations of the universal relational operator-bundle connection $\mathcal{A}_\mu$: the *mition* and *tantron*. They are *not* substrate quanta of Φ or Θ; after BEH breaking their transverse modes are massive, BRST-physical, with Proca-like content (Definitions 6.192, 9.258 and 9.348). Ledger-wise they live in the *connection* register and influence $\Sigma_{\mu\nu}$ only indirectly through the constitutive mapping $\Sigma[\Phi, \Theta]$ (eq. (10.101)); they are therefore *not* τ–kairos registers. Their projectors commute with the typed/triad structure and remain TT-orthogonal, so the graviton TT readout stays purely geometric (Proposition 10.9 and Definition 10.3). On a realized weave configuration they are credible dark-sector candidates (misalignment/freeze-in) subject to portal constraints; Section 10.16 summarizes: connection origin, BEH-massive transverse modes, typed/triad isolation, TT-safeguarding of the graviton, and cosmological viability.

One-line map (quick recall, retained verbatim). τ–kairos = TT-null temporal/coherence tensor with $\{\text{scalars } S^{(b)}, S^{(L)}, \tilde{S}^{(p)}\} \oplus \{\text{CK vectors } A^{(\pm)}\}$; CK has $\hat{\mathcal{F}}^{(\tau)}_{\mu\nu} = 2\bar{\nabla}_{[\mu}K^{(\tau)}_{\nu]}$. It never creates GW polarizations and is reported via T–L–O stamps. **Mition/Tantron** = BEH-massive spin-1 connection quanta living in the *connection* ledger; typed/TT safe; viable DM channels; not τ registers.

Chapter 11: The Graviton and Chronogeometric Gravity

Chapter 11 completes the quantisation of the typed, background–covariant spin-2 carrier on a certified plateau $\mathfrak{P}$ (with band tags BRST–closed and commuting) and reads all graviton observables on the physical space $\mathcal{H}_{\rm phys} = H^0(\hat{Q}_{\rm BRST})$. Using the York projector from Chapter 11, the graviton is *defined* as the transverse–traceless projection of the metric fluctuation (Definition 10.3 and eq. (10.4)),

$$\hat{h}_{\mu\nu} := \Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\, \delta\hat{g}_{\mu\nu}, \qquad \bar{\nabla}^{\mu}\hat{h}_{\mu\nu} = 0, \quad \bar{g}^{\mu\nu}\hat{h}_{\mu\nu} = 0,$$

so tracelessness and transversality hold by construction. Temporal/coherence fluctuations $\hat{\tau}_{\mu\nu} = \delta\hat{t}_{\mu\nu}$ are TT–null in the weave, insulating the graviton channel from the τ–kairos layer; parasymmetric masks accordingly do not admit spin-2 TT excitations (Lemma 10.28 and Definition 10.4).

Typed dynamics are obtained by TT–sandwiching the spin-2 Lichnerowicz operator (plus sectoral mixing), yielding a sector–resolved TT wave operator $K^{[\mathrm{TT}],(a)}{}_{\mu\nu}{}^{\alpha\beta}$ and a strictly TT Feynman propagator $G^{\mathrm{F},[\mathrm{TT}],(a)}{}_{\underline{\mu\nu}}{}^{\rho\sigma}$. Its causal (Heaviside) representation uses the $\bar{\Sigma}$–order $\Theta_{\bar{\Sigma}}$, and equal–time limits via $\bar{\Sigma}$–covariant point–splitting reproduce the typed ETCR. On $\mathfrak{P}$, BRST–closedness and commutation of all selectors make these kernels gauge-parameter independent (Nielsen–flat) and regulator-safe; hyperbolicity of the principal symbol ensures retarded/advanced supports lie on $\bar{\Sigma}$–cones, giving typed microcausality.

The covariant algebra is then stated in terms of the TT Pauli–Jordan kernel $\Delta^{[\mathrm{TT}]} = G^{\mathrm{ret}}_{[\mathrm{TT}]} - G^{\mathrm{adv}}_{[\mathrm{TT}]}$ and the typed Peierls bracket $\{F, G\}_{\mathrm{P}}$ for gauge-invariant functionals $F[h], G[h]$; the equal–time limit recovers the canonical ETCR on any admissible $\bar{\Sigma}$–Cauchy slice. A $\bar{\Sigma}$–foliation $t : \mathcal{X}_q \to \mathbb{R}$ is used only to *present* equal–time relations; on the diagnostic realized reference configuration one proves the canonical↔Peierls equivalence, so predictions are foliation–independent.

Because the weave selectors commute, the graviton field resolves *triadically* by sector,

$$\hat{h}^{(a)}_{\mu\nu} = \Pi^{(a)}\,\hat{h}_{\mu\nu} = \Pi^{(a)}\Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\,\delta\hat{g}_{\mu\nu}, \qquad a \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\},$$

with $\sum_a \Pi^{(a)} = \mathbf{1}$ and $\Pi^{(a)}\Pi^{(b)} = \delta_{ab}\Pi^{(a)}$. In particular, the *Correlational Graviton* $\hat{h}^{(\mathrm{corr})} = \Pi^{(\mathrm{corr})}\hat{h}$ is the typed spin-2 projection of the interaction–sourced channel, while $\hat{\tau}$ remains TT–null. Quantum mechanically, the graviton is *composite* across the triad: its Källén–Lehmann representation on $\mathcal{H}_{\rm phys}$ carries a triadic residue vector $\vec{Z} = (Z_{\rm corr}, Z_{\rm vac}, Z_{\rm spec})$ and admits a corresponding triadic Fock factorisation, clarifying how geometric sources feed each sector.

Quantization of the spin–2 sector on the diagnostic realized reference configuration. The chapter quantizes the geometric (spin–2) sector on the realized, certified plateau $(\mathcal{X}_q, \bar{\Sigma}_{\mu\nu})$ using the Relational Levi–Civita connection $\bar{\nabla}$ that satisfies $\bar{\nabla}_\lambda\bar{\Sigma}_{\mu\nu} = 0$ (cf. Definition 6.7). The radiative carrier is fixed by the background–covariant York–type projector $\Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}$, and the graviton field operator is defined intrinsically by

$$\hat{h}_{\mu\nu} \;:=\; \Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\,\delta\hat{g}_{\mu\nu}, \qquad \bar{g}^{\mu\nu}\hat{h}_{\mu\nu} = 0, \quad \bar{\nabla}^{\mu}\hat{h}_{\mu\nu} = 0,$$

so tracelessness and transversality hold by construction. A key structural result is that the coherence/temporal fluctuation $\hat{\tau}_{\mu\nu} := \delta\hat{t}_{\mu\nu}$ is TT–null in the weave, hence spin–2 radiation is *purely metric* in all physical readouts (cf. Section 11.1.3).

Canonical and covariant quantizations; agreement on a plateau. Quantization is presented in two equivalent languages. (i) *Canonical:* impose equal–time commutators on the typed pair $(\hat{h}_{\mu\nu}, \hat{\Pi}^{\mu\nu})$ *after* band–sandwiching with $P_x(\lambda_{\rm UV})$ and projecting with $\Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}$, preserving BRST hygiene and localizing the algebra within the $\bar{\Sigma}$–induced foliation. (ii) *Covariant:* use the Peierls bracket generated by the TT–projected Lichnerowicz operator so that the commutator is the (TT) difference of retarded/advanced Green operators supported on the $\bar{\Sigma}$–null cone. On a certified plateau $\mathfrak{P}$ the two definitions agree and yield the same realized propagator (cf. Section 11.1).

Typed Källén–Lehmann representation. The realized TT two–point function admits a triad–resolved Källén–Lehmann representation on $\mathcal{H}_{\rm phys}$,

$$\Delta^{(2),a}(q) \;=\; \frac{Z_a}{q^2+i\epsilon} \;+\; \int_0^\infty \frac{\rho_a^{(2)}(\mu^2)\,d\mu^2}{q^2-\mu^2+i\epsilon}, \qquad Z_a \geq 0, \quad \rho_a^{(2)} \geq 0,$$

with residue vector $\vec{Z} = (Z_{\rm corr}, Z_{\rm vac}, Z_{\rm spec})$ read on the plateau. This makes precise how the TT–typed graviton can carry a physical triadic admixture—only the component that survives BRST/plateau certification is realized (positivity as in Ch. 8).

Typed graviton–Tantrakyma vertex and sectoral structure. Typed interactions are built as shadows of the bi–local matter–geometry coupling ($\Phi\Phi \leftrightarrow \Theta\Theta$). The TT–typed, linearized graviton–Tantrakyma vertex is defined by

$$\hat{V}^{\mu\nu}(x) := \left(\Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}\right)^{\mu\nu}{}_{\alpha\beta}\, \frac{\delta S_{\rm int}\left[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}\right]}{\delta \hat{h}_{\alpha\beta}(x)}\bigg|_{\mathfrak{P}}, \qquad \hat{V}^{\mu\nu} = \hat{V}^{\nu\mu}, \quad \bar{\Sigma}_{\mu\nu}\hat{V}^{\mu\nu} = 0,$$

and decomposes orthogonally into triadic blocks $\hat{V}^{(a)\mu\nu} := \Pi^{(a)}\hat{V}^{\mu\nu}$ with $[\Pi^{(a)}, \Pi^{[\mathrm{TT}]}_{\bar{\Sigma}}] = 0$ (cf. Definitions 11.24 and 11.64). Hermiticity, $\bar{\Sigma}$–cone support, and TT preservation follow from the weave algebra and from the TT–null τ leg, ensuring that spin–2 radiative content remains purely metric (cf. Section 11.1.3).

TT Ward identity and block–diagonal couplings. A typed Ward identity controls the vertex:

$$k_\mu\, \hat{V}^{[\mathrm{TT}],(a)\mu\nu}(k) = 0, \qquad \bar{\Sigma}_{\mu\nu}\, \hat{V}^{[\mathrm{TT}],(a)\mu\nu}(k) = 0, \quad \forall\, a \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\},$$

with τ–insertions TT–null. Internal graviton lines in typed Feynman graphs are therefore TT propagators attached to TT vertices in the *same* triadic block; linearized couplings are block–diagonal in a (cf. Proposition 11.77 and Corollary 11.73).

Modal expansion in a typed TT polarization basis. For practical calculations, expand the vertex in a typed TT polarization basis $\{e_{\mu\nu}^{(s,a)}(k;x)\}$ (cf. Definition 11.18), defining modal amplitudes

$$\mathcal{V}^{(s,a)}(k;x) := \int d^d x'\, \mathcal{K}^{\mu\nu}(x,x')\, e_{\mu\nu}^{(s,a)}(k)\, e^{-ik\cdot x'},$$

so that

$$\hat{V}_{\mu\nu}^{[\mathrm{TT}],(a)}(x) = \sum_s \int \frac{d^d k}{(2\pi)^d}\, e_{\mu\nu}^{(s,a)}(k)\, \mathcal{V}^{(s,a)}(k;x) \;+\; \text{h.c.},$$

compatible with the sector–resolved TT mode expansion of $\hat{h}_{\mu\nu}^{(a)}$ and with the triadic propagators (cf. eqs. (11.86), (11.97) and (11.127) and Definition 11.51).

Mode decomposition from Gaiamiti fluctuations. In IQR, geometry is emergent: the graviton is the quantum excitation of the field whose expectation realizes $\bar{\Sigma}_{\mu\nu}$. Working on $\mathfrak{P}$ with $\hat{h}_{\mu\nu} := \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\, \delta\hat{g}_{\mu\nu}$, the coherence sector $\hat{\tau}_{\mu\nu}$ remains TT–null and does not contribute to spin–2 propagation (cf. Section 11.1.3).

Weave self–consistency: algebra, causality, and law diagnostics. The same $\bar{\Sigma}$ that governs causal propagation via the typed wave operator also fixes the quantum algebra via $\Delta^{[\mathrm{TT}]}$. The TT law residual $\mathbf{R}^{[\mathrm{TT}]}$ (cf. Definition 11.6) is naturally expressed through the Peierls construction; when the TT Ward identity holds on $\mathfrak{P}$, the residual vanishes and the law visibility saturates. Hence typed quantum algebra, causal support, and law diagnostics are mutually compatible on the diagnostic realized reference configuration; a typed Parasymmetric TLO layer is attached for the graviton to close the construction (cf. Proposition 11.14).

Chronogeometric Einstein equations (diagnostic realized reference configuration, operator, and linearised forms). On the diagnostic realized reference configuration $(\mathcal{X}_q, \bar{\Sigma}_{\mu\nu})$ with Relational Levi–Civita connection $\bar{\nabla}$ satisfying $\bar{\nabla}_\lambda \bar{\Sigma}_{\mu\nu} = 0$ (cf. Definition 6.7), the semi–classical law for expectation–level chronogeometry is stated in the Σ–language (cf. Definition 11.106 and eq. (11.191)):

$$\bar{G}_{\mu\nu}[\bar{\Sigma}] \;+\; \Lambda\, \bar{\Sigma}_{\mu\nu} \;=\; \kappa\, \bar{T}_{\mu\nu}^{\mathrm{total}}, \qquad \bar{G}_{\mu\nu} := \bar{R}_{\mu\nu} - \tfrac{1}{2}\, \bar{\Sigma}_{\mu\nu}\, \bar{R} \;\; (\textit{Definition 11.138 and eq. (11.260)}).$$

The diagnostic realized reference configuration law follows from the *relational Einstein–Hilbert action* on the same background (cf. Section 11.5.3, Definition 11.105, and eq. (11.188)) and is accompanied by covariant conservation identities

$$\bar{\nabla}^\mu \bar{G}_{\mu\nu} \equiv 0, \qquad \bar{\nabla}_\mu^{(\mathrm{rel})}\, \bar{T}_{\mathrm{total}}^{\mu\nu} = 0 \quad (\textit{eq. (11.192)}).$$

In coordinates adapted to $(\mathcal{X}_q, \bar{\Sigma})$, the unified Ricci tensor is obtained by contracting the $\bar{\Sigma}$–Riemann tensor written with the Relational Levi–Civita symbols, yielding the Christoffel form

$$\bar{R}_{\mu\nu} = \partial_\mu \Gamma^\lambda{}_{\nu\lambda} - \partial_\nu \Gamma^\lambda{}_{\mu\lambda} + \Gamma^\lambda{}_{\mu\alpha}\Gamma^\alpha{}_{\nu\lambda} - \Gamma^\lambda{}_{\nu\alpha}\Gamma^\alpha{}_{\mu\lambda},$$

and $\bar{R} = \bar{\Sigma}^{\mu\nu}\bar{R}_{\mu\nu}$ by the $\bar{\Sigma}$–trace. Physically, since $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$, the stationarity condition balances "metric curvature'' with "coherence/temporal curvature''; the limit $\bar{t}_{\mu\nu} \to 0$ reproduces the usual Einstein–Hilbert dynamics in g, while $\bar{R}[\bar{\Sigma}] - R[\bar{g}]$ encodes chronogeometric effects.

Unified operator–valued form. Beyond the diagnostic realized reference configuration equation, the chapter gives an operator–valued, retarded bitensor representation

$$\hat{G}_{\mu\nu}(x) = \int d\mu_{\bar{\Sigma}}(x')\, \hat{\mathcal{C}}_{\mu\nu}{}^{\rho\sigma}(x;x') \circ \Big[\mathcal{U}_{\bar{\Sigma}}(x \leftarrow x')_{\rho}{}^{\rho'}\, \mathcal{U}_{\bar{\Sigma}}(x \leftarrow x')_{\sigma}{}^{\sigma'}\, \hat{T}^{\rm total}_{\rho'\sigma'}(x')\Big] \quad (eq.\ (11.256)),$$

and a local symbolic form (densities/parallel transport suppressed)

$$\hat{G}_{\mu\nu}[\hat{\Sigma}](x) = \hat{\mathcal{C}}_{\mu\nu}{}^{\rho\sigma}(x) \circ \hat{T}^{\rm total}_{\rho\sigma}(x), \qquad A \circ B := \tfrac{1}{2}(AB+BA) \quad (eq.\ (11.257)),$$

with the total source split into diagonal, interaction, and coherence/torsion pieces,

$$\hat{T}^{\rm total}_{\rho\sigma} = \hat{T}^{(\Phi)}_{\rho\sigma} + \hat{T}^{(\Theta)}_{\rho\sigma} + \hat{T}^{(\Phi\Theta)}_{\rho\sigma} + \hat{T}^{(\tau)}_{\rho\sigma} \quad (eq.\ (11.258)).$$

Linearisation, typed spin–2 operator, and Σ–causal propagation. For radiative content, linearisation about $\bar{\Sigma}$ defines the *linearised Einstein operator*

$$\mathcal{E}_{\mu\nu}{}^{\rho\sigma}[\bar{\Sigma}]\, h_{\rho\sigma} := \frac{\delta}{\delta \bar{\Sigma}_{\rho\sigma}}\Big(\bar{G}_{\mu\nu}[\bar{\Sigma}] + \Lambda\, \bar{\Sigma}_{\mu\nu}\Big)\Big|_{\bar{\Sigma}} h_{\rho\sigma}, \qquad \bar{\nabla}^{\mu}(\mathcal{E}_{\mu\nu}{}^{\rho\sigma} h_{\rho\sigma}) = 0 \quad (eq.\ (11.181)).$$

York–projecting onto spin–2 yields the typed wave operator governing the graviton carrier,

$$K^{[\rm TT]}_{\mu\nu}{}^{\alpha\beta} := \Big[\Pi^{[\rm TT]}_{\bar{\Sigma}} \circ \mathcal{E}[\bar{\Sigma}] \circ \Pi^{[\rm TT]}_{\bar{\Sigma}}\Big]_{\mu\nu}{}^{\alpha\beta} \quad (eq.\ (11.182)),$$

which underpins the Σ–causal retarded/advanced Green functions and the Peierls algebra used elsewhere in the chapter (cf. Sections 11.5.4 and 11.7). Accordingly, TT kernels propagate on the $\bar{\Sigma}$ microcausal cone, ensuring consistency with the quantum bracket framework; diagnostic realized reference configuration–level diagnostics are packaged as a residual $\mathbf{R}^{[\rm Ein]}$ and visibility $\Lambda^{[\rm Ein]}_{\rm law}$, which saturate when the TT Ward identities and the Bianchi/relational conservation conditions hold.

Chapter 11 thus recasts Einstein's equations in a chronogeometric form keyed to $\bar{\Sigma}$: the definitions, conservation laws, causal support, and radiative (TT) content are made intrinsic to the unified tensor and its Levi–Civita geometry, while the operator–valued law, its linearised carrier, and diagnostic realized reference configuration instrumentation ensure all statements are read on the same BRST/Nielsen–clean, realized platform. The chapter provides a typed, background–covariant and BRST–consistent graviton construction: definition by York TT projection (Definition 10.3 and eq. (10.4)); sector–aware TT wave operators and propagators with causal support; a covariant (Peierls) algebra recovering ETCR on slices; and a triadic decomposition whose residues quantify correlational, vacuum and spectral content. All readings are made on $\mathfrak{P}$ and commute with the weave instrumentation, ensuring sector-clean, spin-clean and dialectically typed measurements consistent with the Chapter 11 realized weave configuration (Definitions 10.3 and 10.4 and Lemma 10.28).

BEH of the Chrono–Kymon: typed structure and consequences. *(1) TT graviton is blind to the chrono–kymon (no BEH "leakage" into spin–2).* The spin–2 carrier is the York–projected metric fluctuation

$$\hat{h}_{\mu\nu} \;=\; \Pi^{[\rm TT]}_{\bar{\Sigma}}\, \delta\hat{g}_{\mu\nu}, \qquad \bar{\nabla}^{\mu}\hat{h}_{\mu\nu} = 0, \quad \bar{g}^{\mu\nu}\hat{h}_{\mu\nu} = 0,$$

while the coherence/temporal fluctuation is $\hat{\tau}_{\mu\nu} := \delta\hat{t}_{\mu\nu}$. The weave algebra implies *TT–nullity of the coherence leg*

$$\left(\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\right)^{\mu\nu}{}_{\alpha\beta}\,\hat{\tau}^{\alpha\beta} = 0, \qquad \Rightarrow \qquad \langle \hat{h}, \hat{\tau} \rangle_{\mathrm{TT}} = 0,$$

so any would–be mixing that could shift the spin–2 pole is projected out (cf. Section 11.1.3). Consequently, the TT Dyson equation

$$\left[\Delta^{[\mathrm{TT}]}(k)\right]^{-1} = K^{[\mathrm{TT}]}(k) \; - \; \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\Sigma_{hh}(k)\,\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}, \qquad K^{[\mathrm{TT}]} := \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]} \circ \mathcal{E}[\bar{\Sigma}] \circ \Pi_{\bar{\Sigma}}^{[\mathrm{TT}]},$$

has the τ-induced self–energy $\Sigma_{hh}^{(\tau)}$ *vanishing* in the TT block:

$$\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\Sigma_{hh}^{(\tau)}(k)\,\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]} = 0,$$

so the TT pole remains at $k^2 = 0$ with positive residue $Z_{\mathrm{grav}} > 0$. Equivalently, the Källén–Lehmann form in TT is unchanged (cf. eq. (11.182) and the typed KL discussion in Section 11.1).

(2) Ward identities keep spin–2 couplings purely metric and block–diagonal. For any typed triadic block $a \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\}$, the TT vertex obeys

$$k_\mu\,\hat{V}^{[\mathrm{TT}],(a)\mu\nu}(k) = 0, \qquad \bar{\Sigma}_{\mu\nu}\,\hat{V}^{[\mathrm{TT}],(a)\mu\nu}(k) = 0,$$

and τ–insertions are *TT–null* within vertices and internal lines (cf. Proposition 11.77 and Corollary 11.73). Hence, typed Feynman graphs with internal gravitons use *TT propagators hooked to TT vertices in the same block*; no spin–1 (chrono–kymon) BEH structure can generate a mass term for $h_{\mu\nu}$.

(3) Where the BEH lives: the chrono–kymon's own spin–1 sector. The BEH mechanism acts in *spin–1 typed channels*, not in spin–2. Abstractly, in its sector the chrono–kymon quadratic kernel reads

$$\left[\mathcal{D}^{(\mathrm{CK})}(k)\right]^{-1}_{\alpha\beta} = \underbrace{\mathcal{K}^{(\mathrm{CK})}_{\alpha\beta}(k)}_{\text{kinetic, }\Sigma\text{-causal}} \; - \; \underbrace{\mathcal{M}^{2\,(\mathrm{CK})}_{\alpha\beta}}_{\text{BEH mass operator}},$$

with $\mathcal{M}^{2\,(\mathrm{CK})}$ generated by broken internal directions (the usual BEH pattern, now phrased on the $\bar{\Sigma}$ diagnostic realized reference configuration). Since $\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}$ acts on *symmetric rank–2* tensors and is orthogonal to the chrono–kymon's *spin–1* subspace,

$$\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\;\mathcal{M}^{2\,(\mathrm{CK})}\;\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]} = 0,$$

by type/geometry, not by fine–tuning. Therefore, even if the chrono–kymon acquires a BEH mass $m_{\mathrm{CK}}^2 > 0$ in its sector, the graviton's typed KL representation

$$\Delta^{(2),a}(q) = \frac{Z_a}{q^2 + i\epsilon} + \int_0^\infty \frac{\rho_a^{(2)}(\mu^2)\,d\mu^2}{q^2 - \mu^2 + i\epsilon}, \qquad Z_a \geq 0,\; \rho_a^{(2)} \geq 0,$$

keeps its massless pole: no $\mathcal{O}(m_{\mathrm{CK}}^2)$ shift appears in TT (cf. Definition 11.51 and eq. (11.86)).

Bottom line. Chapter 11's quantization and TT Ward structure make the statement precise: the chrono–kymon may undergo BEH in its *own spin–1 typed sector*, but this does not induce, modify, or mix a BEH mass in the graviton. Mathematically, TT–nullity of τ and the typed Ward identities enforce

$$\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\left\{\hat{\tau},\ \mathcal{M}^{2\,(\mathrm{CK})},\ \text{mixed } (h{-}\tau) \text{ kernels}\right\}\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}=0,$$

so the *spin–2 pole stays at* $k^2=0$ with Nielsen–safe residue, while any BEH physics of the chrono–kymon is *confined to spin–1 observables* in its own (typed) sector.

BEH of the Gaiaton (radial/trace mode in the Gaiamiti block). *(1) Radial mass from the typed Hessian; positivity on* H^0*.* The Gaiaton is the *radial/trace* (spin–0) excitation in the Gaiamiti ($\Phi\Phi$) manifold, orthogonal to the TT Goldstone sheet. On a certified plateau $\mathfrak{P}$, its pole is fixed by the *typed radial mass operator* extracted from the band–prepared Hessian of the Gaiamiti potential (global setting):

$$m_A^2 \;=\; \lambda_{\mathrm{rad}}\Big(\mathsf{M}_{\Phi}^{[\mathrm{rad}]}\Big) \;>\; 0, \qquad \Delta_A(k) \;=\; \frac{1}{k^2-m_A^2+i0^+} \;\text{ on }\; \mathcal{H}_{\mathrm{phys}}, \quad \text{(cf. Definition 9.250)}$$

with KL–positivity on H^0 (cf. eq. (7.12)). This realizes a single scalar pole $k^2=m_A^2$ (no ghosts/tachyons) as summarized in Section 9.17.4.

(2) Gauged case: BEH for internal vectors and a gauge–independent Gaiaton pole. When Φ carries an internal gauge action,

$$D_\mu\,\Phi=\partial_\mu\Phi-ig\,A_\mu\cdot\Phi,$$

the SSB background $\langle\Phi\rangle$ generates a *vector* BEH mass matrix for the broken generators, while the longitudinal would–be Goldstones form BRST quartets and decouple; unbroken generators remain massless (cf. Section 9.17.4 and Proposition 9.257). In this *gauged* setting the Gaiaton mass is obtained from the *Apeiron* (gauged–radial) operator,

$$m^2_{A,\mathrm{gauged}} \;=\; \lambda_{\mathrm{rad}}\Big(\mathsf{M}^{[\mathrm{rad}]}_{\Phi,\mathrm{Apeiron}}\Big), \qquad \text{(cf. Definition 9.259)}$$

and both the vector masses and the Gaiaton pole are Nielsen–safe on $\mathfrak{P}$:

$$\frac{\partial\, m^2_{A,\mathrm{gauged}}}{\partial\xi}=0, \qquad \frac{\partial\, M_V^2}{\partial\xi}=0 \quad \text{(cf. Theorem 9.351)}.$$

Thus BEH reorganizes the *spin–1* spectrum (massive broken, massless unbroken) without introducing gauge–parameter dependence into the scalar Gaiaton pole.

(3) Orthogonality to spin–2: no TT mass term from the Gaiaton. Because the TT projector annihilates pure traces,

$$\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\Big[S(x)\,\bar{\Sigma}_{\mu\nu}\Big]=0 \qquad \forall\, S,$$

any mixing of the radial/trace scalar with the TT graviton is projected out. Equivalently, at the level of self–energies and vertices,

$$\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}\,\Sigma_{hh}^{(\mathrm{Tr})}(k)\,\Pi_{\bar{\Sigma}}^{[\mathrm{TT}]}=0, \qquad k_\mu\,\hat{V}^{[\mathrm{TT}]\mu\nu}=0, \quad \bar{\Sigma}_{\mu\nu}\hat{V}^{[\mathrm{TT}]\mu\nu}=0,$$

so the York–projected graviton carrier remains massless and purely metric (cf. eq. (11.182), Proposition 11.77, and Corollary 11.73).

Bottom line. The Gaiaton is a *gapped* scalar set by the typed radial curvature of the Gaiamiti potential,

$$\Delta_A(k) = \left(k^2 - m_A^2 + i0^+\right)^{-1},$$

with m_A^2 read either from $\mathsf{M}_\Phi^{[\mathrm{rad}]}$ (global) or from its gauged Apeiron counterpart, both *Nielsen–safe* on $\mathfrak{P}$ (cf. Definitions 9.250 and 9.259 and Theorem 9.351). Internal gauging triggers BEH *for vectors*, not for the spin–2 channel; the TT graviton remains massless by projection/orthogonality, while the Gaiaton's scalar pole stays gauge–independent and positive on H^0, completing the realized Gaiamiti spectrum (cf. Section 9.17.4 and Proposition 9.257).

Part IV: The Standard Model

Chapter 12: The Standard Model

Chapter 12 consolidates the Standard Model within the holosymmetric programme by showing how $G_{\mathrm{SM}} = \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ is singled out by the Holosymmetric Selection Principle (HSP): Stage I is a self-consistency sieve (unitarity/BRST viability), and Stage II is a comparative interferometric tomography that enforces maximal relational coherence and orthogonality to alternatives [52, 117, 112] (Section 12.2). In this setting, gauge bosons are the BRST-physical excitations of the *internal* gauge connection $A_\mu^{\ I}$ on the Tantrakyma bundle, with Yang–Mills dynamics carried by the curvatures $F_{\mu\nu}^{\ I}$ (Definition 12.95; cf. [123, 38]); in parallel, the Operator Bundle Connection $\mathcal{A}_\mu$ has curvature $\mathcal{F}_{\mu\nu} = \partial_\mu \mathcal{A}_\nu - \partial_\nu \mathcal{A}_\mu + i[\mathcal{A}_\mu, \mathcal{A}_\nu]$ and enters the realized weave configuration-compatible transport and curvature split [36, 37] (Definitions 6.192 and 12.96). Fermionic kymons appear as operator-valued spinor sections whose one-generation content matches the familiar $(3,2)_{1/6}$, $(1,2)_{-1/2}$, $(3,1)_{2/3}$, $(3,1)_{-1/3}$, $(1,1)_{-1}$, $(1,1)_0$ assignments [38] (Section 12.4.1; [124]), with subscripts denoting $Y/2$ consistent with the GMN convention used in the chapter.

Electroweak symmetry breaking is treated as a vacuum alignment in the Tantrakyma sector, and the Gell–Mann–Nishijima relation $Q = I_3 + \frac{1}{2}Y$ is *derived*—not postulated—as the unique unbroken generator that leaves the vacuum invariant [38] (Section 12.4.3 and eq. (12.107); cf. [125, 126]). Flavor then enters as geometry: Yukawa structure and diagonalisation produce CKM/PMNS mixing, while the global "family frame" turns these into parallel-transport holonomies $\mathcal{P}\exp\int \mathcal{A}^{(F)}$ [38, 127] (Section 12.5.5 and eq. (12.134)). Confinement is recast as gauge-induced spectral filtering: the color-singlet projector P_{singlet} realises the hadronic sector as a gauge-invariant image inside the emergent Hilbert space, and BRST cohomology identifies the physical space, tying unitarity to the same projector architecture [38, 117] (Proposition 12.128, Section 12.3, and eq. (12.77); cf. [128]). These ingredients are then lifted back into HSP: anomaly freedom and BRST nilpotency supply the Stage I viability condition, while the interferometric coherence functional on the physical sector implements Stage II selection, yielding the SM as the unique holosymmetric fixed point among admissible candidates [117, 110, 111] (eq. (12.46), Theorem 12.57, and Section 12.2).

Beyond this core, the chapter develops two operational extensions germane to phenomenology. First, the neutrino sector accommodates Majorana options and a seesaw hierarchy within the Tantrakyma formalism, consistent with the flavor geometry above [129, 130, 131, 127] (Section 12.7.1). Second, "dark sectors" are characterised not ontologically but operationally: a state is dark relative to G_{SM} if it registers under a holosymmetric coherence projector for some hidden G while remaining spectrally orthogonal to all SM observables [112] (*see Definition 12.77*), providing a concrete tomography-based criterion for hidden dynamics (Section 12.5.4). A brief side thread outlines a state-dependent, unitary evolution across black-hole formation/evaporation within the holocosmic background, situating the construction amidst modern information-theoretic perspectives [22]. In sum, Chapter 12 does not append the SM to the framework; it *carves* it from the operator-geometric substrate via holosymmetric interferometry, with each textbook structure re-expressed as a consequence of relational selection and cohomological admissibility [52, 117, 112].

Realized weave configuration-compatible transport and the operator–bundle picture

The basic kinematic datum is a covariant "split" derivative that respects both geometry and the operator structure of fields on the certified plateau (Section 12.4.4). The realized weave configuration-compatible connection is

$$\nabla_\mu \;=\; \nabla_\mu^{(\mathrm{LC})} \;+\; i\,\mathrm{ad}_{\mathcal{A}_\mu} \quad \text{(Definitions 6.192 and 12.1)},$$

where $\nabla_\mu^{(\mathrm{LC})}$ is the Levi–Civita part and $\mathrm{ad}_{\mathcal{A}_\mu}(X) := [\mathcal{A}_\mu, X]$ is the inner derivation generated by the universal operator–bundle connection $\mathcal{A}_\mu \in \mathrm{End}(\mathcal{H}_{\mathrm{em}})$. With this split, all symmetry statements are tied to ∇_μ: the Euler–Lagrange operator for $\hat{\Theta}$ transforms covariantly under any admissible internal $G \subset G_{\mathrm{int}}$ on a certified plateau (definition "realized weave configuration-compatible G-symmetry", eqs. eq. (12.37)), so that

$$\mathrm{EL}[\hat{\Theta}] \;\mapsto\; U\,\mathrm{EL}[\hat{\Theta}]\,U^{-1}, \qquad U \in G \text{ (DRRC-admissible)}.$$

Here "DRRC-admissible" means admissible with respect to the diagnostic realized reference configuration of Definition 9.185. Intuitively: the Levi–Civita part transports spacetime indices; the $\mathrm{ad}_{\mathcal{A}_\mu}$ part transports operator content in $\mathrm{End}(\mathcal{H}_{\mathrm{em}})$; and the internal G-action is threaded in a way that keeps the total dynamics covariant on $\mathfrak{P}$.

For fermionic carriers living on

$$\mathrm{End}(\mathcal{H}_{\mathrm{em}}) \otimes \mathcal{S} \otimes E_n,$$

the total (realized weave configuration-compatible) split derivative is

$$\mathcal{D}_\mu \hat{\psi}_n \;=\; \nabla_\mu^{(\mathcal{S})} \hat{\psi}_n \;+\; i\,[\mathcal{A}_\mu, \hat{\psi}_n] \;+\; i\,g\,A_\mu^{\ I}\,\rho_n(T_I)\,\hat{\psi}_n,$$

with $\nabla_\mu^{(\mathcal{S})}$ the spin connection on $\mathcal{S}$, $A_\mu^{\ I} T_I$ the internal gauge field (see Definition 12.95), and ρ_n the representation on E_n. Its curvature splits cleanly into Lorentz, operator-bundle, and internal pieces (Lemma Lemma 12.87):

$$[\mathcal{D}_\mu, \mathcal{D}_\nu]\hat{\psi}_n \;=\; R_{\mu\nu}^{(\mathcal{S})} \cdot \hat{\psi}_n \;+\; i\,[\mathcal{F}_{\mu\nu}, \hat{\psi}_n] \;+\; i\,g\,F_{\mu\nu}^{\ I}\,\rho_n(T_I)\,\hat{\psi}_n,$$

where

$$\mathcal{F}_{\mu\nu} = \partial_\mu \mathcal{A}_\nu - \partial_\nu \mathcal{A}_\mu + i\,[\mathcal{A}_\mu, \mathcal{A}_\nu] \qquad \text{(Definition 12.96)},$$
$$F_{\mu\nu}^{\ I} = \partial_\mu A_\nu^{\ I} - \partial_\nu A_\mu^{\ I} + f^I{}_{JK}\, A_\mu^{\ J} A_\nu^{\ K}.$$

This decomposition powers the "hygiene" checks used later: each sector's curvature is measured and controlled separately while remaining compatible with the total transport $\mathcal{D}_\mu$ (Lemma 12.87).

On the diagnostic realized reference configuration $\mathfrak{P}$, the internal gauge kinetics are governed by the Yang–Mills action (Definition 12.98, eq. eq. (12.113)):

$$S_{\mathrm{YM}}[A] \;=\; -\frac{1}{2}\int_{\mathfrak{P}} \sqrt{|g|}\, d^d x\; \kappa_{IJ}\, F_{\mu\nu}^{\ I}\, F^{\mu\nu\, J},$$

with κ_{IJ} the invariant Killing metric on the internal Lie algebra. In flat coordinates this reduces to the standard form, and in $d = 4$ it projects onto the familiar

$$\mathrm{SU}(3)_C \oplus \mathrm{SU}(2)_L \oplus \mathrm{U}(1)_Y \qquad \text{(Lemma Lemma 12.99)}.$$

Crucially, the operator–bundle sector $\mathcal{A}_\mu$ and the internal gauge sector $A_\mu^{\ I}$ remain distinguished but consistently coupled through $\mathcal{D}_\mu$; this is what lets the chapter enforce covariance for composite operator observables built from fields in $\mathrm{End}(\mathcal{H}_{\mathrm{em}})$ (see also the unified split in Section 12.4.4).

Finally, meters are introduced operator-geometrically and are only deployed on certified plateaux so that readouts are BRST/Nielsen stable (Definition Definition 12.16). In practice this means: for any typed meter $\mathcal{M}_\tau$,

$$\big\langle\!\big\langle \mathcal{M}_\tau \big\rangle\!\big\rangle_{\mathrm{DRRC}} \text{ depends only on the BRST cohomology class,} \qquad \frac{\partial}{\partial \xi}\big\langle\!\big\langle \mathcal{M}_\tau \big\rangle\!\big\rangle_{\mathrm{DRRC}} = 0,$$

where $\big\langle\!\big\langle\, \cdot\, \big\rangle\!\big\rangle_{\mathrm{DRRC}}$ denotes evaluation on the diagnostic realized reference configuration of Definition 9.185, ξ is a gauge/Nielsen parameter, and $\hat{Q}_{\mathrm{BRST}}$ is the nilpotent charge selecting the physical space $\mathcal{H}_{\mathrm{phys}}$ (BRST background in Section 12.3). Because transport is realized weave configuration-compatible and the meters are defined in the operator–bundle language, the resulting pole/residue extractions and charge readouts commute with all admissible $G \subset G_{\mathrm{int}}$ on $\mathfrak{P}$, ensuring that symmetry statements proved with ∇_μ are faithfully realized by what the meters actually see (typed-witness context in Definition 9.187).

Anomaly meters, SM calibration, and minimality

Chapter 12 assembles the mixed and cubic anomaly constraints into the "anomaly block" (eq. (12.46)) and evaluates them with diagnostic realized reference configuration meters on the certified plateau $\mathfrak{P}$. For a chiral spectrum $\{f\}$ with hypercharge Y_f and non-abelian

representations R_f, the six local anomaly meters read

$$\begin{aligned}
\sum_f Y_f\, T_2^{\mathrm{SU}(3)}(R_f) &= 0 && [\,\mathrm{SU}(3)_C^2\!-\!\mathrm{U}(1)_Y\,],\\
\sum_f Y_f\, T_2^{\mathrm{SU}(2)}(R_f) &= 0 && [\,\mathrm{SU}(2)_L^2\!-\!\mathrm{U}(1)_Y\,],\\
\sum_f Y_f^{\,3} &= 0 && [\,\mathrm{U}(1)_Y^3\,],\\
\sum_f Y_f &= 0 && [\,\mathrm{grav}^2\!-\!\mathrm{U}(1)_Y\,],\\
\sum_f A^{\mathrm{SU}(3)}(R_f) &= 0 && [\,\mathrm{SU}(3)_C^3\,],\\
\sum_f A^{\mathrm{SU}(2)}(R_f) &= 0 && [\,\mathrm{SU}(2)_L^3\ (\mathrm{local})],
\end{aligned}$$

together with the global Witten test for SU(2):

$$\#\{\mathrm{SU}(2)\text{ doublets (counting color)}\} \equiv 0 \pmod 2.$$

Here $T_2(R)$ is the Dynkin index (with $T_2(\mathbf{2}) = T_2(\mathbf{3}) = \frac{1}{2}$ in the standard normalization) and $A(R)$ is the cubic anomaly coefficient (with $A(\mathbf{3}) = -A(\overline{\mathbf{3}}) = 1$ for SU(3)).

For the one-generation Standard-Model assignment listed in table 12.1, each meter vanishes explicitly. Writing all fields as left-handed Weyl spinors,

$$Q_L : (\mathbf{3},\mathbf{2},+\tfrac{1}{6}),\quad u_R^c : (\overline{\mathbf{3}},\mathbf{1},-\tfrac{2}{3}),\quad d_R^c : (\overline{\mathbf{3}},\mathbf{1},+\tfrac{1}{3}),\quad L_L : (\mathbf{1},\mathbf{2},-\tfrac{1}{2}),\quad e_R^c : (\mathbf{1},\mathbf{1},+1),$$

(with an optional $\nu_R^c : (\mathbf{1},\mathbf{1},0)$ which is anomaly-inert), the per-generation cancellations are

$$\begin{aligned}
\mathrm{SU}(3)_C^2\!-\!\mathrm{U}(1)_Y:&\quad 2\cdot\tfrac{1}{6}\,T_2(\mathbf{3}) + (-\tfrac{2}{3})\,T_2(\overline{\mathbf{3}}) + (\tfrac{1}{3})\,T_2(\overline{\mathbf{3}}) = \tfrac{1}{6}-\tfrac{1}{3}+\tfrac{1}{6} = 0,\\
\mathrm{SU}(2)_L^2\!-\!\mathrm{U}(1)_Y:&\quad 3\cdot(\tfrac{1}{6})\,T_2(\mathbf{2}) + 1\cdot(-\tfrac{1}{2})\,T_2(\mathbf{2}) = \tfrac{1}{4}-\tfrac{1}{4} = 0,\\
\mathrm{U}(1)_Y^3:&\quad 6\big(\tfrac{1}{6}\big)^3 + 3\big(-\tfrac{2}{3}\big)^3 + 3\big(\tfrac{1}{3}\big)^3 + 2\big(-\tfrac{1}{2}\big)^3 + (1)^3 = 0,\\
\mathrm{grav}^2\!-\!\mathrm{U}(1)_Y:&\quad 6\big(\tfrac{1}{6}\big) + 3\big(-\tfrac{2}{3}\big) + 3\big(\tfrac{1}{3}\big) + 2\big(-\tfrac{1}{2}\big) + (1) = 0,\\
\mathrm{SU}(3)_C^3:&\quad 2\,A(\mathbf{3}) - A(\overline{\mathbf{3}}) - A(\overline{\mathbf{3}}) = 2-1-1 = 0,\\
\text{Witten test}:&\quad 3\times(\text{quark doublet}) + 1\times(\text{lepton doublet}) = 4 \equiv 0 \pmod 2.
\end{aligned}$$

These equalities constitute the "Standard-Model calibration fixture" (Proposition 12.26): all six local anomaly meters read

$$\big\langle\!\big\langle \mathcal{A}_i \big\rangle\!\big\rangle_{\mathfrak{P}} = 0, \qquad i = 1,\dots,6,$$

validating the normalization/tagging in table 12.1 and ensuring Nielsen-flatness of certified readouts on $\mathfrak{P}$.

Under these constraints—together with "no exotics" in the chiral spectrum and the presence of a single nontrivial abelian factor—the chapter states the minimality/uniqueness of the internal gauge law:

$$G_{\mathrm{SM}} = \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_Y,$$

namely, it is the unique minimal chiral gauge sector that solves the anomaly block (paragraph "Minimality and uniqueness").

Representation-theoretic sufficiency bridge to G_{SM}

The central statement (Theorem 12.57) asserts: if a candidate internal law A is (i) compact, local, and Tantrakyma-invariant; (ii) chirally admissible with the one-generation SM matter content; (iii) completely anomaly-free (local + global); and (iv) minimal (no extra chiral matter; exactly one nontrivial U(1)), then the induced K-action on $\mathcal{H}_{\mathrm{mat}}$ is unitarily equivalent to the SM action. Equivalently, there exists a unitary intertwiner $U : \mathcal{H}_{\mathrm{mat}} \to \mathcal{H}_{\mathrm{mat}}$ such that

$$\rho_A(k) \;=\; U\,\rho_{\mathrm{SM}}(k)\,U^{-1} \quad \forall\, k \in K, \qquad d\rho_A(X) \;=\; U\,d\rho_{\mathrm{SM}}(X)\,U^{-1} \quad \forall\, X \in \mathfrak{k},$$

with $\mathfrak{k} = \mathrm{Lie}(K)$.

Proof highlights (structural constraints). *(1) Weak factor from pseudoreal doublets.* Chiral admissibility with SM matter includes left-handed weak doublets. In a compact setting, a nontrivial two-dimensional *pseudoreal* irrep forces an $\mathfrak{su}(2)$ simple summand at minimal rank. Thus

$$\mathfrak{k} \;\supset\; \mathfrak{su}(2) \qquad \Rightarrow \qquad K \;\supset\; \mathrm{SU}(2)_L.$$

(2) Color factor from complex triplets with nonvanishing cubic index. The presence of color triplets and anti-triplets with a nonzero cubic anomaly coefficient $A(R)$ requires a simple factor whose fundamentals are complex and support a nonvanishing third-order invariant. Among compact simples, the minimal such choice is $\mathfrak{su}(3)$, hence

$$\mathfrak{k} \;\supset\; \mathfrak{su}(3) \qquad \Rightarrow \qquad K \;\supset\; \mathrm{SU}(3)_C.$$

(3) Abelian factor fixed by fractional charges and GMN. Diagnostic realized reference configuration charges obey the Gell–Mann–Nishijima relation

$$Q \;=\; I_3 \,+\, \tfrac{1}{2}\,Y,$$

and the observed fractional Q for quarks requires a hypercharge generator Y that is independent of the $\mathfrak{su}(2)$ Cartan. Minimality (exactly one nontrivial abelian factor) hence fixes

$$\mathfrak{k} \;\supset\; \mathfrak{u}(1)_Y \qquad \text{and no extra } \mathfrak{u}(1) \text{ factors.}$$

Additional abelian factors would either leave uncanceled mixed anomalies or demand exotic chiral matter, violating (iii) or (iv).

Putting (1)–(3) together and invoking complete anomaly freedom yields the Lie-algebra isomorphism

$$\mathfrak{k} \;\cong\; \mathfrak{su}(3) \oplus \mathfrak{su}(2) \oplus \mathfrak{u}(1),$$

hence (up to global issues and overall normalization of Y)

$$K \;\simeq\; \mathrm{SU}(3)_C \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_Y.$$

Relational character and unitary equivalence. The "relational character" (Definition 12.54) packages the K-action on $\mathcal{H}_{\mathrm{mat}}$ as a class function

$$\chi_A(k) \;:=\; \mathrm{Tr}_{\mathcal{H}_{\mathrm{mat}}}\Big(\rho_A(k)\Big), \qquad k \in K,$$

which decomposes into irreducible characters as

$$\chi_A \;=\; \sum_{\lambda \in \widehat{K}} m_\lambda\, \chi^\lambda, \qquad m_\lambda \in \mathbb{N}.$$

Peter–Weyl orthogonality gives the "filters" used later in Stage II:

$$\langle \chi_A, \chi^\lambda \rangle_K \;:=\; \int_K \overline{\chi^\lambda(k)}\, \chi_A(k)\, d\mu_K(k) \;=\; m_\lambda,$$

so matching the relational character to the SM data fixes the multiplicities m_λ and, hence, the isomorphism class of the representation. Under (i)–(iv), the spectrum and multiplicities agree with the SM one-generation assignment, which implies the existence of the unitary intertwiner U above. This completes the bridge claimed in Theorem 12.57.

EWSB, Yukawas, and masses on the diagnostic realized reference configuration

Expanding the electroweak scalar about the vacuum on the certified plateau as

$$\bar{\Theta} \;=\; \langle H \rangle \;=\; \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix} \qquad \text{(Lemma 12.94)[38]},$$

and writing the Yukawa sector in the standard doublet notation,

$$\mathcal{L}_Y \;=\; -\,\bar{Q}_L\, \tilde{H}\, Y_u\, u_R - \bar{Q}_L\, H\, Y_d\, d_R - \bar{L}_L\, H\, Y_e\, e_R - \bar{L}_L\, \tilde{H}\, Y_\nu\, \nu_R + \mathrm{h.c.}, \qquad \tilde{H} := i\sigma^2 H^* \text{[38]},$$

one obtains the fermion mass Lagrangian after EWSB,

$$\mathcal{L}_{\mathrm{mass}}^{(\mathrm{ferm})} = -\,\bar{d}_L\, M_d\, d_R - \bar{u}_L\, M_u\, u_R - \bar{e}_L\, M_e\, e_R - \bar{\nu}_L\, M_D\, \nu_R + \mathrm{h.c.},$$

$$M_f = \frac{v}{\sqrt{2}}\, Y_f, \quad \text{for } f \in \{u, d, e\},$$

$$M_D = \frac{v}{\sqrt{2}}\, Y_\nu,$$

with the standard relations read on the diagnostic realized reference configuration [38, 112]. Each Yukawa matrix admits a singular-value (biunitary) decomposition $Y_f = U_{f_L}^\dagger\, y_f^{\mathrm{diag}}\, U_{f_R}$, whence

$$M_f \;=\; \frac{v}{\sqrt{2}}\, U_{f_L}^\dagger\, y_f^{\mathrm{diag}}\, U_{f_R}, \qquad m_f^{(i)} \;=\; \frac{v}{\sqrt{2}} \Big(\text{sing. values}(Y_f)\Big)^{(i)} \text{[38]}.$$

Diagnostic realized reference configuration-admissible unitary rotations bring the kinetic terms to canonical form and diagonalize the masses; charged-current mixing then appears as

$$V_{\mathrm{CKM}} \;=\; U_{u_L}\, U_{d_L}^\dagger,$$

$$U_{\mathrm{PMNS}} \;=\; U_{\ell_L}\, U_{\nu_L}^\dagger$$

(Section 12.5.5, Proposition 12.115, and eq. (12.134))[38, 127].

Readouts are performed in the scalar τ-channel, preserving TT purity (typed-meter and witness framework Definitions 9.187 and 12.16).

Transport is consistently handled by the realized weave configuration-compatible split derivative $\mathcal{D}_\mu$; the Yukawa tensors Y_f behave as internal scalars on the diagnostic realized reference configuration and thus preserve meter hygiene and covariance under the operator–bundle structure [36, 37] (realized weave configuration-compatibility Definition 6.192, Lemma 12.87, and Section 12.4.4). In particular, the scalar excitation $h(x)$ around $\bar{\Theta}$ couples proportionally to mass,

$$\mathcal{L}_{h\bar{f}f} \;=\; -\frac{h}{v}\left(\bar{d}_L M_d d_R + \bar{u}_L M_u u_R + \bar{e}_L M_e e_R + \bar{\nu}_L M_D \nu_R\right) + \text{h.c.},$$

which is aligned with the Yukawa tensors (diagnostic realized reference configuration alignment in Section 12.5.5) [38].

Compact summary. Before EWSB, gauge invariance forbids fermion mass terms. After EWSB, masses arise as the singular values of the Yukawas:

$$m_f \;=\; \frac{v}{\sqrt{2}}\,\text{sing. values}(Y_f),$$

and the Higgs–fermion couplings are aligned with Y_f, i.e. proportional to M_f/v in the mass basis (Section 12.5.5) [38, 112].

Gauge bosons and the GMN relation

On the certified plateau $\mathfrak{P}$, the physical gauge bosons are the BRST-physical *transverse* poles of the internal connection (Definition Definition 12.95) [52, 117, 38]: eight gluons g^a_μ $(a = 1, \ldots, 8)$ from $\mathrm{SU}(3)_C$, together with the electroweak primordial fields W^i_μ $(i = 1, 2, 3)$ and B_μ. After spontaneous symmetry breaking (SSB), the charged sector is formed by

$$W^\pm_\mu \;=\; \frac{1}{\sqrt{2}}\left(W^1_\mu \mp i\, W^2_\mu\right) \qquad \text{(Definition 12.95)[38]},$$

while the neutral sector mixes as

$$\begin{pmatrix} Z_\mu \\ A_\mu \end{pmatrix} \;=\; \begin{pmatrix} \cos\theta_W & -\sin\theta_W \\ \sin\theta_W & \cos\theta_W \end{pmatrix} \begin{pmatrix} W^3_\mu \\ B_\mu \end{pmatrix}, \qquad \tan\theta_W \;=\; \frac{g'}{g}\,[38],$$

so that A_μ is the massless eigenvector that couples to the unbroken generator $\hat{Q}$ determined in Section 12.4.3 (see also eq. (12.107)) [125, 126, 38].

The neutral mass matrix descending from the BEH sector (Higgs kinetic term) has the standard form

$$\mathcal{L}^{\text{neutral}}_{\text{mass}} \;=\; \frac{v^2}{8}\begin{pmatrix} W^3_\mu & B_\mu \end{pmatrix} \begin{pmatrix} g^2 & -g\,g' \\ -g\,g' & g'^2 \end{pmatrix} \begin{pmatrix} W^{3\mu} \\ B^\mu \end{pmatrix},$$

which is diagonalized by the rotation above, yielding

$$\begin{aligned} M_W &= \frac{g\,v}{2}, \\ M_Z &= \frac{v}{2}\sqrt{g^2+g'^2}, \\ M_\gamma &= 0 \end{aligned} \qquad \text{(DRRC EWSB context, Lemma 12.94)[38, 112].}$$

Here "DRRC" denotes the diagnostic realized reference configuration of Definition 9.185. The covariant derivative on a field with weak isospin generators T^a and hypercharge Y reads

$$\begin{aligned} D_\mu &= \partial_\mu + i\,g\,T^a W_\mu^a + i\,\frac{g'}{2}\,Y\,B_\mu \\ &= \partial_\mu + i\,\frac{g}{\sqrt{2}}\Big(T^+ W_\mu^+ + T^- W_\mu^-\Big) + i\,e\,Q\,A_\mu \\ &\quad + i\,\frac{g}{\cos\theta_W}\Big(T^3 - \sin^2\theta_W\,Q\Big)\,Z_\mu, \end{aligned}$$

with $T^\pm := T^1 \pm iT^2$, $e := g\sin\theta_W = g'\cos\theta_W$, and

$$Q \;=\; I_3 + \frac{Y}{2} \qquad \text{(Gell–Mann–Nishijima/GMN relation, eq. (12.107))[125, 126, 38].}$$

Thus, for all realized species, the fermionic charges satisfy $Q = I_3 + \frac{1}{2}Y$, exactly matching the neutral/charged mixing enforced by the BEH matrix, and the massless eigenvector A_μ couples to the unbroken electromagnetic generator $\hat{Q}$ on $\mathfrak{P}$ [38, 112] (unbroken generator from Lemma 12.94; emergence in Section 12.4.3).

Neutrino sector: seesaw and $U(1)_L$ breaking

Chapter 12 introduces a minimal lepton-number–violating extension with a gauge-singlet scalar Φ_ν whose vacuum expectation value (VEV) spontaneously breaks the global symmetry $U(1)_L$ and generates a Majorana mass for right-handed neutrinos [129, 130, 131, 127] (Section 12.7.1 and Proposition 12.148). The relevant Yukawa and Majorana couplings on the certified plateau $\mathfrak{P}$ are [38, 127]

$$\mathcal{L} \;\supset\; -\,\bar{L}_L\,\tilde{H}\,Y_\nu\,\nu_R \;-\; \tfrac{1}{2}\,y^{(\nu)}\,\Phi_\nu\,\overline{\nu_R^c}\nu_R \;+\; \text{h.c.}, \qquad \tilde{H} := i\sigma^2 H^*,$$

where Y_ν and $y^{(\nu)}$ act on the family fibre and commute with diagnostic realized reference configuration transport (operator/bundle covariance; Definitions 6.192 and 12.106 and Section 12.4.4). When [38, 131]

$$\langle H\rangle \;=\; \frac{1}{\sqrt{2}}\begin{pmatrix}0\\ v\end{pmatrix}, \qquad \langle\Phi_\nu\rangle \;=\; v_\nu,$$

one obtains the Dirac and Majorana blocks

$$M_D \;=\; \frac{v}{\sqrt{2}}\,Y_\nu, \qquad M_R \;=\; y^{(\nu)}\,v_\nu,$$

consistent with the DRCC vacuum alignment (Lemma 12.94) and the lepton-number–violating trigger (Proposition 12.148). In the $(\nu_L,\, \nu_R^c)$ basis the mass Lagrangian is

$$\mathcal{L}_{\text{mass}} \;=\; -\,\frac{1}{2}\,\begin{pmatrix}\nu_L^{\top} & \nu_R^{\top}\end{pmatrix} C^{-1}\begin{pmatrix}0 & M_D\\ M_D^{\top} & M_R\end{pmatrix}\begin{pmatrix}\nu_L\\ \nu_R^{c}\end{pmatrix} \;+\; \text{h.c.},$$

which is the Type-I seesaw with $m_L = 0$ [129, 130, 127] (diagnostic realized reference configuration formulation in Section 12.7.1). For a large Majorana scale $\|M_R\| \gg \|M_D\|$, block-diagonalization yields the effective light-neutrino mass matrix

$$m_\nu^{\text{eff}} \;=\; -\,M_D\,M_R^{-1}\,M_D^{\top} \;+\; \mathcal{O}(M_R^{-2}) \qquad \text{(eq. (12.209))[130, 127, 112].}$$

Parametrically, in any consistent operator norm,

$$\|m_\nu^{\text{eff}}\| \;\sim\; \frac{\left\|v\,Y_\nu\right\|^2}{\left\|y^{(\nu)}\right\|\,v_\nu},$$

matching the scaling quoted in eq. (12.209) [112]. This reproduces the Weinberg operator at low energies,

$$\mathcal{L}_{\text{eff}} \;=\; -\,\frac{1}{2}\,(\bar{L}_L\tilde{H})\,C^{-1}\,c_5\,(\tilde{H}^{\top}L_L^{c}) \;+\; \text{h.c.}, \qquad c_5 \;=\; Y_\nu\,M_R^{-1}\,Y_\nu^{\top},$$

so that after EWSB $m_\nu^{\text{eff}} = \frac{v^2}{2}\,c_5$, demonstrating consistency with the dimension-five Weinberg limit (Proposition Proposition 12.148) [112, 127]. In this construction, $U(1)_L$ breaking is encoded in $\langle\Phi_\nu\rangle \neq 0$, and the light eigenstates may be chosen Majorana ($\chi = \chi^c$) in the decoupling regime, with family phases carried by the PMNS holonomy and transforming under charge conjugation [127] (Definitions 12.136 and 12.156 and Proposition 12.115).

Families and anomaly/HSP compatibility

Triplicating the chiral multiplets by introducing a flat family fibre $\mathcal{F}$ leaves all anomaly constraints unchanged (Subsection Section 12.5.4; see also the anomaly block eq. (12.46)). Because each entry of the anomaly block is linear in traces over representations, replication by N_F families simply multiplies every contribution by N_F:

$$\sum_{f\in\text{all fam.}} Y_f\,T_2^G(R_f) = \sum_{a=1}^{N_F}\sum_{i\in 1\text{ gen.}} Y_i\,T_2^G(R_i) \;=\; N_F\sum_{i\in 1\text{ gen.}} Y_i\,T_2^G(R_i),$$

$$\sum_{f\in\text{all fam.}} Y_f^{\,3} = N_F\sum_{i\in 1\text{ gen.}} Y_i^{\,3}, \qquad \sum_{f\in\text{all fam.}} Y_f \;=\; N_F\sum_{i\in 1\text{ gen.}} Y_i,$$

$$\sum_{f\in\text{all fam.}} A^G(R_f) = N_F\sum_{i\in 1\text{ gen.}} A^G(R_i),$$

and similarly for all mixed and cubic non-abelian entries. Since each one-generation sum vanishes (SM calibration fixture Proposition 12.26, with assignments in table 12.1), all family-replicated sums vanish as well. Hence Stage-I viability is unchanged and the holosymmetric score remains $\mathcal{C}(A) = 1$ (Stage-I sieve in Section 12.2).

The family structure is implemented in transport by a flat, unitary auxiliary connection $\mathcal{A}_\mu^{(F)}$ acting on $\mathcal{F}$ (family fibre setup Definition 12.106); the total realized weave configuration-compatible derivative extends as

$$\begin{aligned} \mathcal{D}_\mu &\longrightarrow \mathcal{D}_\mu^{\mathrm{tot}} = \mathcal{D}_\mu + i\,\mathcal{A}_\mu^{(F)}, \\ \mathcal{A}_\mu^{(F)} &\in \mathfrak{u}(N_F) \\ &\quad \text{(realized weave configuration–compatibility background} \\ &\quad \text{Definition 6.192 and Lemma 12.87).} \end{aligned}$$

with vanishing family curvature and unitary holonomy,

$$\begin{aligned} F_{\mu\nu}^{(F)} &:= \partial_\mu \mathcal{A}_\nu^{(F)} - \partial_\nu \mathcal{A}_\mu^{(F)} + i\,[\mathcal{A}_\mu^{(F)}, \mathcal{A}_\nu^{(F)}] \;=\; 0, \\ U^{(F)}[\gamma] &:= \mathcal{P}\exp\!\Big(i\!\int_\gamma \mathcal{A}^{(F)}\Big) \in U(N_F) \\ &\quad \text{(Definition 12.106 and eq. (12.124)).} \end{aligned}$$

Flatness ensures path-independent family phases and preserves diagnostic realized reference configuration hygiene; unitarity preserves the inner product on the family fibre. Because $\mathcal{A}_\mu^{(F)}$ acts trivially on gauge indices and commutes with BRST on the diagnostic realized reference configuration,

$$\big[\hat{Q}_{\mathrm{BRST}},\, \mathcal{A}_\mu^{(F)}\big] \;=\; 0, \qquad \big[\hat{Q}_{\mathrm{BRST}},\, \mathcal{D}_\mu^{\mathrm{tot}}\big] \;=\; 0 \quad \text{(Sections 12.3 and 12.5.4)},$$

the family replication neither disturbs the anomaly block nor the Stage-I BRST structure. In particular, mixing matrices (CKM/PMNS) may be viewed as family holonomies derived from $\mathcal{A}_\mu^{(F)}$,

$$V_{\mathrm{CKM}},\, U_{\mathrm{PMNS}} \;\text{ as holonomies }\; U^{(F)}[\gamma] \quad \text{(Proposition 12.115 and eq. (12.134))},$$

while all certified meters on $\mathfrak{P}$ remain Nielsen-flat and BRST-safe (typed meters and witnesses in Definitions 9.187 and 12.16).

QCD composites via color–gauge projection

With BRST projection and confinement on the certified plateau $\mathfrak{P}$, physical hadrons arise as *color singlets* built from the n-quark sector (n=2 for mesons, n=3 for baryons) [38, 128] (color projector and spectral filtering in Definition 12.126 and Proposition 12.128; BRST diagnostic realized reference configuration set-up in Section 12.3). The hadronic Hilbert space is obtained by applying the color–singlet projector to the quark sector,

$$\mathcal{H}_{\mathrm{hadron}} \;:=\; P_{\mathrm{singlet}}\Big(\mathcal{H}_{\mathrm{quark}}^{(n)}\Big) \;\subset\; \mathcal{H}_{\mathrm{em}} \quad \text{(Corollary Corollary 12.125, eq. eq. (12.154))}.$$

Since P_{singlet} is gauge invariant, it commutes with the BRST charge on $\mathfrak{P}$ [117],

$$\big[\hat{Q}_{\mathrm{BRST}},\, P_{\mathrm{singlet}}\big] \;=\; 0,$$

so the BRST cohomology descends to the singlet subspace and colored excitations are projected out (see also Proposition 12.120 and Theorem 12.133).

Mesons (n=2). In color space $\mathbf{3}\otimes\overline{\mathbf{3}}=\mathbf{1}\oplus\mathbf{8}$, and the singlet projector may be written (Haar average) [30, 38]

$$(P_{\mathbf{1}})_i{}^j{}_k{}^\ell \;=\; \int_{\mathrm{SU}(3)} dU\; U_i{}^j\,(U^\dagger)_k{}^\ell \;=\; \frac{1}{3}\,\delta_i{}^\ell\,\delta_k{}^j.$$

Acting on bilinears yields color-singlet meson operators [128]

$$\mathcal{O}_M(x) \;=\; \bar{q}_j(x)\,\Gamma\,q^j(x),$$

whose two-point function displays only singlet poles in the chosen typed channel τ [128, 38]

$$\langle\,\mathcal{O}_M(x)\,\mathcal{O}_M^\dagger(0)\,\rangle^{(\tau)}_{\mathfrak{P},c} \;=\; \sum_{n\in\mathrm{Meson}_\tau} |\langle 0|\mathcal{O}_M|n,\tau\rangle|^2\;\Delta_n(x),$$

with Δ_n the (Euclidean/Minkowski) propagator of the n-th meson state (typed meters/witnesses in Definitions 9.187 and 12.16).

Baryons (n=3). For three quarks one has $\mathbf{3}\otimes\mathbf{3}\otimes\mathbf{3}=\mathbf{1}\oplus\mathbf{8}\oplus\mathbf{8}\oplus\mathbf{10}$, and the singlet is selected by the totally antisymmetric tensor [38, 128]:

$$\mathcal{O}_B(x) \;=\; \epsilon_{ijk}\,q^i(x)\,q^j(x)\,q^k(x)\,,\qquad (P_{\mathbf{1}})_{i_1i_2i_3}{}^{j_1j_2j_3} \;=\; \frac{1}{6}\,\epsilon_{i_1i_2i_3}\,\epsilon^{j_1j_2j_3}.$$

The corresponding correlator isolates baryonic singlet poles [128]

$$\langle\,\mathcal{O}_B(x)\,\overline{\mathcal{O}}_B(0)\,\rangle^{(\tau)}_{\mathfrak{P},c} \;=\; \sum_{n\in\mathrm{Baryon}_\tau} |\langle 0|\mathcal{O}_B|n,\tau\rangle|^2\;\Delta_n(x).$$

Typed placement and TT purity. All hadronic operators are placed in a specified typed channel τ so that certified meters interrogate only the intended spin/parity/flavor sector; this typed placement preserves TT purity throughout the extraction pipeline (typed architecture Definitions 9.187 and 12.16) [38]. In summary,

$$\boxed{\mathcal{H}_{\mathrm{hadron}} \;=\; P_{\mathrm{singlet}}\Big(\mathcal{H}^{(2)}_{\mathrm{quark}}\oplus\mathcal{H}^{(3)}_{\mathrm{quark}}\oplus\cdots\Big)\;\subset\;\mathcal{H}_{\mathrm{em}}}$$

realizes mesons and baryons as BRST-physical color singlets, in accordance with Corollary 12.125, eq. (12.154), and Theorem 12.133 [117, 128].

Antimatter (what it is on the diagnostic realized reference configuration, and how it shows up)

In the IQR/Tantrakyma architecture, the antimatter sector is *not* a separate theory: it is the charge–conjugate sector of the *same* kymonic fields, with (i) conjugate gauge representations, (ii) conjugate family phases, (iii) identical BRST/diagnostic realized reference configuration certification, and (iv) the same color–singlet projection for (anti)hadrons [38, 117, 128]. Neutrinos are special: if they are Dirac, they carry distinct antineutrinos; if they are Majorana (e.g. in the seesaw regime) the light states are self–conjugate and lepton–number–violating observables such as $0\nu\beta\beta$ become the antimatter signature [129, 130, 131, 127] (Section 12.7.4, Definition 12.136, and eq. (12.220)).

Three structural pillars (on a certified plateau). Together these enforce particle–antiparticle pairing for the SM sector on $\mathfrak{P}$:

1. complex unitary representations of the internal connection (and the induced $*$–structure on the operator bundle) [30, 38];
2. relativistic causality with a positive spectral measure on certified plateaux (CPT and conjugate poles) [38, 30];
3. neutrality of the family fibre with C-conjugated holonomy phases [127].

All of this is framed in the diagnostic realized reference configuration language of Section 12.4.4, Definitions 12.95, 12.96 and 12.106, Propositions 12.88 and 12.115, and eqs. (12.124) and (12.134).

Operational content. Dualizing

$$(R,\, U^{(F)}) \;\longmapsto\; (\overline{R},\, U^{(F)*})$$

leaves certified visibilities and typed SynTh witnesses invariant, so matter and antimatter occupy the *same* cell of the Symmetry–Asymmetry matrix (the holosymmetric lift is block-/cone–preserving) [117, 38]. At the field-theory level one has the matching of residues/poles [38, 128, 30]:

$$\begin{aligned} &\mathrm{Res}_{p^2\to m^2}\,\Big\langle 0\Big|T\{\psi(x)\,\bar\psi(0)\}\Big|0\Big\rangle \;\sim\; Z\,\Pi_{(m,s)}(p) \\ \Longleftrightarrow\;\; &\mathrm{Res}_{p^2\to m^2}\,\Big\langle 0\Big|T\{\psi^c(x)\,\overline{\psi^c}(0)\}\Big|0\Big\rangle \;\sim\; Z\,\Pi_{(m,s)}(p). \end{aligned}$$

Quadrant functionals obey (Definition 9.187)

$$\mathcal{Q}[\rho_0;\,\mathcal{O}] \;=\; \mathcal{Q}[\rho_0;\,\mathcal{O}^C], \qquad \mathcal{Q}\Big[\,|\Omega\rangle;\,\Pi_\alpha\Big] \;=\; \mathcal{Q}\Big[\,|\overline{\Omega}\rangle;\,\Pi_\alpha\Big],$$

so typed extraction makes no distinction between particle and antiparticle channels beyond the conjugation of additive charges and phases [38].

Hadronic realization. Color–singlet projection together with BRST cohomology produces hadrons and anti–hadrons as conjugate singlets [128, 117]:

$$\begin{aligned} &\text{mesons:} \quad q\bar q \;\text{ vs. }\; \bar q q, \\ &\text{baryons:} \quad \epsilon_{ijk}\, q^i q^j q^k \;\text{ vs. }\; \epsilon^{ijk}\, \bar q_i \bar q_j \bar q_k, \end{aligned}$$

with conjugate poles sharing the same (m, s) and carrying opposite additive charges (Definition 12.126, Proposition 12.120, and Theorem 12.133).

Neutrinos and the seesaw/Majorana limit (self-conjugacy)

Turning on symmetric Majorana blocks yields the general neutrino mass Lagrangian [127]:

$$\mathcal{L}_{\text{mass}}^{\text{Maj+Dirac}} \;=\; -\tfrac{1}{2}\,\Psi_D^{\top} C^{-1} \begin{pmatrix} m_L & m_D \\ m_D^{\top} & M_R \end{pmatrix} \Psi_D \;+\; \text{h.c.}, \qquad m_L = m_L^{\top}, \quad M_R = M_R^{\top},$$

where m_L and M_R are family endomorphisms on $(\mathcal{F}, \mathcal{A}^{(F)})$ (Definition 12.106), and one may take $\Psi_D^{\top} = (\nu_L,\ \nu_R^c)$.

In the Type–I seesaw limit ($m_L = 0$, $\|M_R\| \gg \|m_D\|$), block–diagonalization gives a *symmetric* light-neutrino mass matrix [129, 130, 131, 127]

$$m_\nu^{\text{eff}} \;=\; -\,m_D\, M_R^{-1}\, m_D^{\top} \;+\; \mathcal{O}(M_R^{-2}),$$

so the light mass eigenstates can be chosen Majorana ($\chi = \chi^c$). In this sense the $\mathbf{D}_{\mathcal{C}}$-dyad collapses: the dual acts trivially on each eigenstate (self–conjugacy), consistent with Proposition 12.158.

Diagonalizing the symmetric matrix defines the leptonic mixing as a *family holonomy* [127]:

$$U_{\nu_L}^{\top}\, m_\nu^{\text{eff}}\, U_{\nu_L} \;=\; \text{diag}(m_1, m_2, m_3), \qquad U_{\text{PMNS}} \;=\; U_{\ell_L}\, U_{\nu_L}^{\dagger},$$

with phases transforming under charge conjugation by $U^{(F)} \mapsto U^{(F)*}$ (Definitions 12.136 and 12.156 and Proposition 12.115).

The Axiom of Duality and Antimatter (how the pillars become a theorem)

Chapter 12 reframes antimatter as a *corollary of the Axiom of Duality* (Definition 2.100). The three pillars are presented as concrete incarnations of Duality:

(i) representation duality: $R \leftrightarrow \overline{R}$ (CRP, Definition 12.151),

(ii) spectral duality of poles/residues: KL+CPT (Proposition 12.154),

(iii) family-holonomy duality: $U^{(F)}[\gamma^{-1}] = U^{(F)}[\gamma]^{\dagger}$,
$C:\ U^{(F)} \mapsto U^{(F)*}$ (Definition 12.156).

Typed diagnostic realized reference configuration statement (Section 12.10). *Duality ⇒ Antiparticles (typed).* On a certified plateau $\mathfrak{P}$, any Tantrakyma kymon in a non-self-conjugate irrep acquires a unique conjugate class with the same (m/s) and opposite additive charges; family phases are complex-conjugated, and bound-state singlets map to their conjugates. If the irrep is real/pseudoreal or the relevant charge vanishes (or in the Majorana limit), Duality acts trivially and the field is self–conjugate.

Algebraic face (functorial duality). Formally, Duality is encoded by a contravariant *–functor on the internal representation category,

$$\mathfrak{D}_{\text{int}} : \ \text{Rep}(G_{\text{SM}}) \longrightarrow \text{Rep}(G_{\text{SM}}), \qquad \mathfrak{D}_{\text{int}}(R) = \overline{R}, \ \ \mathfrak{D}_{\text{int}}(U) = U^*,$$

so that, at the object level, $\mathbf{D}_{\mathcal{C}}$ implements charge conjugation

$$\psi \ \longmapsto \ \psi^c \ = \ \mathcal{C}\,\bar{\psi}^T, \qquad \psi^c \in \overline{R},$$

in accordance with Definition 12.151 and Proposition 12.152. This algebraic face sits alongside the geometric (family-holonomy) and spectral (KL+CPT) faces to yield the *Antiparticle Theorem* Corollary 12.172.

Consequence: quadrant invariance. Duality preserves the placement in the Symmetry–Asymmetry matrix (no inter–cell transport) because the holosymmetric lift is block-/cone–preserving; equivalently, there is no-law signalling and $(\bar{\Sigma})$–cone locality is maintained. In short, antimatter is the Duality shadow of the same certified dynamics on $\mathfrak{P}$, with all certified meters and spectral witnesses transforming contravariantly but *invariantly* in value.

The Yang–Mills Mass Gap

Chapter 12 develops two independent axioms–level routes from the operational "diagnostic realized reference configuration" pipeline to a nonzero mass gap in pure Yang–Mills (YM), while making explicit what remains to reach an unconditional, Clay–level solution. The key ingredients are typed, gauge–invariant meters (Definitions 9.187 and 12.16), KL/OS positivity in the continuum (Lemma 12.190), and the guards/plateau workflow that certifies spectral poles (Theorem 12.219) [30, 52, 117]. The section cross–links these pieces to the Continuum Theorem (Theorem 12.249) and the OS area–law route (Theorem 12.251), and clarifies the conditional nature of both routes (see Section 12.13.10) [123, 128, 32].

Operational resolution vs. Clay–level theorem: a guided introduction

Chapter 12 upgrades the diagnostic realized reference configuration pipeline to two axioms–level theorems that each imply a strictly positive first pole in standard glueball channels:

- **Route A (Spectral/guards).** Assuming continuum KL positivity with mild IR regularity, the guards/plateau workflow becomes the *Continuum Guards/Plateau Theorem* Theorem 12.249. On the certified plateau, typed two–point functions admit a KL form (Lemma 12.190); the effective mass is eventually monotone and convergent (Proposition 12.213); and the first pole satisfies $m_* > 0$ by typed certification (Theorem 12.219 and Corollary 12.250) [30].
- **Route B (Wilson loops).** Under OS reflection positivity, an area law for large rectangles yields exponential clustering and a universal lower bound $m \gtrsim c_{\text{cl}}\sqrt{\sigma} > 0$; this is the *OS area–law mass–gap theorem* Theorem 12.251. At this level, typed equality becomes a projection theorem (Proposition 12.216), meter locality reduces to microcausality (Proposition 12.217), and CPT/KL hygiene follows from OS→Wightman reconstruction (Lemma 12.190 and Propositions 12.154 and 12.158) [128, 30].

Both routes import a nonperturbative input—either (A) KL positivity with specified IR control, or (B) an OS–positive area law—so the mass–gap conclusions here are *conditional* on those inputs (see Section 12.13.10) [32].

Modal kinematics, transport, and the correlator kernel

The Chapter 4 "backbone" sets up the Fourfold modal fibre and the gauge–covariant transporter $\mathcal{U}$, from which the typed, gauge–invariant correlator kernel is built. For an admissible path $\gamma : x' \to x$, $\mathcal{U}(x \leftarrow x'; \gamma)$ is unitary, composes functorially, and trivializes on null paths; it assembles both the meter–to–meter transport of the diagnostic realized reference configuration pipeline (Definitions 9.187 and 12.16) and the loop variables that tie into Wilson–loop diagnostics [128]. This backbone targets exactly the Clay–level inputs: (A) it furnishes uniformity/IR guards for continuum correlators used in Theorem 12.249 and Proposition 12.213; (B) it interfaces with area–law control under OS positivity via transporter/loop comparison (Proposition 12.236 and Theorem 12.251) [30, 123].

Operator–valued metric, triadic split, and why it solves (A) and (B)

Chapter 5 introduces the operator–valued metric $\hat{g}_{\mu\nu}$ (second variation of a composite–operator distance) and its triadic split

$$\hat{g} \;=\; \hat{g}^{\mathrm{corr}} \;+\; \hat{g}^{\mathrm{vac}} \;+\; \hat{g}^{\mathrm{spec}},$$

which geometrizes the spectral/IR information needed for both routes [30, 22]. Under KL positivity and mild IR regularity, the guards (Lipschitz/TV/positivity) on diagnostic slopes become theorems, feeding directly into Theorem 12.249 and Proposition 12.213 [55, 30]. Under OS positivity, an area law enforces a finite correlation length in $\hat{g}$ and yields exponential clustering, matching the Wilson–loop bounds and leading to a strictly positive spectral threshold (Proposition 12.236 and Theorem 12.251) [128, 32]. Because typed meters are contractions of the Fourfold kernel, their two–point functions are governed by $\hat{g}^{\mathrm{spec}}$, ensuring positivity/locality control compatible with Lemma 12.190 and Proposition 12.217 [117, 52].

Development of the Yang-Mills Continuum Theorem

Assuming continuum KL positivity with IR regularity, Chapter 12 proves the continuum version of the diagnostic realized reference configuration pipeline [55, 30]:

1. **Certified plateau & IR window.** The mask/morphology and IR guards (Lipschitz/TV/-positivity) hold as theorems on a nonempty plateau $\mathcal{P}$ and an IR window $\mathcal{I}_{\mathrm{IR}} \subset \mathcal{P}$ (Theorem 12.249).

2. **KL form & effective–mass convergence.** Every typed, gauge–invariant two–point admits a KL (Laplace) representation with nonnegative measure, and the effective mass is eventually monotone with $\lim_{t\to\infty} m_{\mathrm{eff}}^{(O,\tau)}(t) = m_O$ (Lemma 12.190 and Proposition 12.213) [55, 22].

3. **Strict positive lower bound.** On $\mathcal{I}_{\mathrm{IR}}$,

$$C_O^{(\tau)}(t) = A_0 e^{-m_O t} + \int_{m_*}^{\infty} A(\mu)\, e^{-\mu t}\, d\mu, \qquad A_0, A(\mu) \geq 0.$$

   hence any isolated pole obeys $m_O \geq m_*^{\mathrm{op}} > 0$ (Corollary 12.250) [30].

4. **Typed equality & meter locality.** After band reduction, typed/untyped extractions coincide (Proposition 12.216), and meter locality follows from visibility additivity and cone–locality at the axioms level (Proposition 12.217) [117, 52].

5. **Typed certification (continuum).** Items (1)–(4) verify the hypotheses of the typed spectral certification theorem, establishing $m_O > 0$ on $\mathcal{P}$ without operational certification (Theorem 12.219) [30].

Altogether this yields a *Typed Spectral Gap in the continuum* with $m_O \geq m_*^{\mathrm{op}} > 0$ and $m_{\mathrm{eff}} \to m_O$ (Corollary 12.250), and underwrites the "Pipeline ⇒ Theorem" corollary (Corollary 12.252) [32, 128].

The Yang-Mills Mass Gap Theorem and OS/Wightman Axioms

In the OS/Wightman framework, assuming OS positivity and an area law for large rectangular Wilson loops, Chapter 12 proves [30, 128, 123, 32]:

1. **Exponential clustering.** For any local, gauge–invariant typed channel,

$$\left|\langle O(x)O(0)\rangle_{E,c}\right| \;\leq\; C_{\mathrm{cl}}\, e^{-c_{\mathrm{cl}}\sqrt{\sigma}\,|x|} \qquad (|x| \gg 1),$$

   by chessboard/Cauchy–Schwarz bounds that tie the connected two–point to a Wilson loop (Proposition 12.236) [128, 30].

2. **Strictly positive spectral threshold.** OS→Wightman reconstruction promotes clustering to a mass gap $m \geq c_{\mathrm{cl}}\sqrt{\sigma} > 0$, and typed effective masses converge to that threshold (Theorem 12.251) [30, 55].

At the axioms level, meter locality is just microcausality with visibility additivity (Proposition 12.217); KL/CPT hygiene descends from OS reconstruction (Lemma 12.190 and Proposition 12.154); and for pure YM the adjoint is real, so duality (charge conjugation) is inert in the glueball channels (Proposition 12.158) [30, 38]. All prerequisites (OS positivity, area law, transporter identifications) are treated as axioms–level inputs; with them, the operational pipeline collapses to a single, self–contained proof (Theorem 12.251 and Corollary 12.252) [128, 30].

YM mass–gap theorem. Under either of two axioms–level inputs, Chapter 12 establishes a strictly positive first pole in every typed, gauge–invariant glueball channel:

1. **Continuum (spectral/guards) route.** *Assumptions:* continuum Källén–Lehmann (KL) positivity with mild IR regularity for YM two–point functions (Lemma 12.190). *Conclusions:* the guards/plateau workflow upgrades to the *Continuum Guards/Plateau Theorem* (Theorem 12.249); on the certified plateau, typed correlators admit a KL form and the effective mass is eventually monotone and convergent (Proposition 12.213). Typed spectral certification then yields a nonzero gap:

$$\begin{aligned} &m_* > 0 \qquad \text{and} \\ &m_{\text{eff}}^{(O,\tau)}(t) \xrightarrow[t\to\infty]{} m_O \quad \text{for each typed channel } (O,\tau) \\ &\qquad (\textit{Theorem 12.219and Corollary 12.250}). \end{aligned}$$

   Equivalently, for any isolated pole one has $m_O \geq m_*^{\text{op}} > 0$ on the certified window (Corollary 12.250).

2. **OS/Wilson–loop (area–law) route.** *Assumptions:* Osterwalder–Schrader (OS) reflection positivity and an *area law* for large rectangles,

$$-\log\langle W[\square(R,T)]\rangle_E = \sigma RT + o(RT), \qquad \sigma > 0,$$

   with transporter/loop identification as in Proposition 12.236. *Conclusions:* exponential clustering of all local gauge–invariant typed correlators and, after OS→Wightman reconstruction, a strictly positive spectral threshold (Theorem 12.251):

$$\left|\langle O(x)O(0)\rangle_{E,c}\right| \leq C_{\text{cl}}\, e^{-c_{\text{cl}}\sqrt{\sigma}\,|x|} \quad \Rightarrow \quad m \geq c_{\text{cl}}\sqrt{\sigma} > 0,$$

   with typed effective masses converging to that threshold. At this level, typed equality becomes a projection theorem and meter locality reduces to microcausality (Propositions 12.216 and 12.217); KL/CPT hygiene follows from OS reconstruction (Lemma 12.190 and Proposition 12.154), and for pure YM the adjoint is real so duality (charge conjugation) is inert in these channels (Proposition 12.158).

Conditional statement of the result. The theorem established in Chapter 12 asserts a *nonzero mass gap* in every typed, gauge–invariant glueball channel, *conditional* on one of two axioms–level inputs. Concretely, for each typed operator/meter channel (as specified by the typed architecture Definitions 9.187 and 12.16), the two–point function admits a Källén–Lehmann representation with nonnegative measure and a strictly positive lowest spectral threshold, and the corresponding effective mass converges to the first pole:

$$m_* > 0, \qquad m_{\text{eff}}^{(O,\tau)}(t) \xrightarrow[t\to\infty]{} m_O.$$

This is the content of the continuum typed certification and gap statements (Lemma 12.190, Proposition 12.213, Theorem 12.219, and Corollary 12.250).

Routes to the statement. *Route A (spectral/guards).* Assuming continuum KL positivity with mild IR control, the guards/plateau workflow becomes the *Continuum Guards/Plateau Theorem* (Theorem 12.249). On the certified plateau, typed correlators have KL form and the effective mass is eventually monotone and convergent, yielding $m_O \geq m_*^{\mathrm{op}} > 0$ in each typed channel (Lemma 12.190, Proposition 12.213, and Corollary 12.250) [55, 30]. *Route B (OS/area law).* Assuming OS reflection positivity and a Wilson–loop area law, exponential clustering is obtained; OS→Wightman reconstruction then gives a strictly positive spectral threshold $m \geq c_{\mathrm{cl}}\sqrt{\sigma} > 0$ and convergence of typed effective masses to that value (Proposition 12.236 and Theorem 12.251) [30, 128]. At this level, typed equality reduces to a projection theorem and meter locality to microcausality; CPT/KL hygiene descends from OS reconstruction (Propositions 12.154, 12.216 and 12.217 and Lemma 12.190), and in pure YM the adjoint is real so the duality (charge conjugation) action is inert in these channels (Proposition 12.158) [30, 38].

Meaning of "typed" in the statement. The gap is asserted *in the channels interrogated by certified meters*: BRST–physical, gauge–invariant, typed operators defined on the certified plateau (Definitions 9.187 and 12.16). In this setting, correlators either possess an isolated first pole at $m_O > 0$ or, equivalently, exhibit exponential decay with rate $\geq m_*^{\mathrm{op}}$, and the effective–mass estimator extracted by the typed procedure converges to m_O (Theorem 12.219 and Corollary 12.250).

Non–unconditional (Clay–level) status. The two routes above are *conditional*: each assumes one nonperturbative input—either (A) KL positivity with specified IR regularity (Route A) or (B) an OS–positive area law (Route B). A Clay–level resolution requires deriving those inputs *within YM itself* [132, 133] and then applying the same pipeline–to–theorem collapse (Section 12.13.10 and Corollary 12.252). These are precisely the nonperturbative facts the Clay Mathematics Institute Millennium Problem on *Quantum Yang–Mills and the Mass Gap* asks one to derive *within* YM [132, 133].

Part V: Cosmology

Chapter 13: Dark Energy and Dark Matter

Chapter 13 reframes the dark sector as a consequence of the dual-field vacuum of *Gaiamiti* (geometric) and *Tantrakyma* (material), rather than as an *ad hoc* addendum to ΛCDM (Sections 13.1 and 13.1.1). Empirically anchored by supernovae and CMB data [134, 135, 136], the chapter proposes that the large but oppositely signed vacuum contributions of the two sectors nearly cancel by dynamical self-regulation, leaving a small residual ε_Λ that acts as dark energy. Operationally, this residue is a symmetry-filtered expectation value—the "global interferometric residue"—whose late-time dynamics are governed by the Spin-0 *Apeiron* (a quintessence-like mode that also unifies with the inflaton in the early universe) (Section 13.2.7). The dark-matter sector is then developed along three complementary tracks: (i) a vector Spin-1 *Chrono–Kymon* (quantum torsion of the Tantrakyma), neutral under G_{SM} and naturally

long-lived; (ii) a scalar Spin-0 *Apeiron* with WIMP-like relic abundance but of geometric origin; and (iii) a "dark gravity" option in which entanglement-induced correlations source halo phenomenology without introducing new particles (Section 13.1.2).

Methodologically, the chapter elevates *selection*—rather than postulation—to first principle. The Holosymmetric Selection Principle (HSP) and its *interferometer* compare entire universal histories in two stages: Stage I prunes those that fail physical self-coherence, and Stage II maximizes the physical holosymmetric overlap among the survivors (Sections 13.1.3 and 13.1.4). A commutator-based *lensing* formalism diagnoses the algebraic "twist" that produces bright/dark interferometric structure, while the comparative verdict is delivered by the interferometer itself (Section 13.2.7). In this frame, dark-matter candidates (Spin-0 vs. Spin-1) are adjudicated as inequivalent K-actions whose cross-overlap vanishes; the realized candidate is the one that yields the "bright fringe" (maximal self-overlap) across the SN/CMB/BAO/lensing/growth effect-families, subject to the operational *visibility* + *spectral-decoupling* test

$$\left\|\mathcal{P}_G^{\mathrm{coh}}\,|\psi\rangle\right\|^2 > 0, \qquad \langle\psi|\mathcal{O}_{\mathrm{SM}}|\psi\rangle_{\mathrm{phys}} \approx 0 \quad (\textit{Sections 13.2.7and 13.2.8}).$$

For dark energy, HSP selects among the three cancellation histories ($\Lambda > 0, = 0, < 0$), with the observed branch read as the unique coherence maximum (Sections 13.2.6 and 13.2.7). The energy budget is then partitioned by projector-filtered expectations into $(\rho_{\mathrm{DE}}, \rho_{\mathrm{DM}}, \rho_{\mathrm{vis}})$ and abundances $(\Omega_{\mathrm{DE}}, \Omega_{\mathrm{DM}}, \Omega_{\mathrm{vis}})$, linking sector dominance to chronogeometric regimes (Section 13.4.7). Finally, the entire construction is located within a timeless, background-free dynamical law—the Universal Quantum Constraint,

$$\hat{H}_{\mathrm{univ}}\,|\overset{\circ}{\boldsymbol{\Psi}}\rangle = 0,$$

from which ordinary Schrödinger evolution for subsystems emerges conditionally by clock-conditioning on $\mathcal{H}_{\mathrm{phys}}$ (Section 13.6).

Total energy from the universal Hamiltonian. Chapter 13 begins by fixing the comoving energy density through the *spectral resolution* of the regulated universal Hamiltonian $\hat{H}_{\mathrm{univ}} = \hat{H}_\Phi + \hat{H}_\Theta + \hat{H}_{\mathrm{int}}$ acting on the emergent/GNS space $\mathcal{H}_{\mathrm{em}}$. In the BRST-physical realized weave configuration, the realized Holo–State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ yields

$$\rho_{\mathrm{tot}} = \frac{1}{\mathrm{Vol}(\mathcal{X}_q)}\left\langle\overset{\circ}{\boldsymbol{\Psi}}\right|\hat{H}_{\mathrm{univ}}\left|\overset{\circ}{\boldsymbol{\Psi}}\right\rangle_{\mathrm{phys}} = \frac{1}{\mathrm{Vol}(\mathcal{X}_q)}\int_{\sigma(\hat{H}_{\mathrm{univ}})} E\,\mathrm{d}\mu_{\overset{\circ}{\boldsymbol{\Psi}}}^{\hat{H}_{\mathrm{univ}}}(E),$$

which fixes both the operational meaning (expectation value per comoving cell) and the measure-theoretic content (projector-valued spectral integral) of ρ_{tot} (see Definition 13.92 and eq. (13.144)). With the universal quantum constraint enforced on $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$, this definition is regulator-ready and sets up the partition of energy components that follows.

Holosymmetric partition and sum rule. The chapter then *resolves the identity* on the BRST-physical space by the coherence projectors

$$\mathcal{P}_{\mathrm{vac}}^{\mathrm{sym}} + \mathcal{P}_{\mathrm{dark}}^{\mathrm{coh}} + \mathcal{P}_{\mathrm{vis}}^{\mathrm{coh}} = \mathbf{1}_{\mathrm{phys}}, \qquad \mathcal{P}_i\mathcal{P}_j = \delta_{ij}\mathcal{P}_i,$$

so that HSP selection cancels cross-interferences and induces the abundance partition

$$\rho_{\mathrm{tot}} = \rho_{\mathrm{DE}} + \rho_{\mathrm{DM}} + \rho_{\mathrm{vis}}, \qquad \Omega_{\mathrm{DE}} + \Omega_{\mathrm{DM}} + \Omega_{\mathrm{vis}} = 1,$$

as formalized in Proposition 13.97 and eqs. (13.149) and (13.150). Conceptually, this ties the *kinematical* (projector) split to the *operational* (spectral) definition above, so every downstream observable can be expressed in terms of ρ_i or Ω_i without ambiguity.

Universe as an HSP fixed point. Finally, the chapter frames cosmic realization as a two-stage HSP adjudication over histories: *Stage I* enforces self-coherence/viability and *Stage II* maximizes holosymmetric overlap, selecting a background on which the $\{\mathcal{P}^{\mathrm{sym}}_{\mathrm{vac}}, \mathcal{P}^{\mathrm{coh}}_{\mathrm{dark}}, \mathcal{P}^{\mathrm{coh}}_{\mathrm{vis}}\}$ split is realized and the visible/DM/DE trichotomy emerges (Conclusion, "A Universe Sculpted by Coherence").

Dark energy (residual vacuum). Applying the symmetric vacuum projector $\mathcal{P}^{\mathrm{sym}}_{\mathrm{vac}}$ to $H_{\mathrm{vac}} := H^{\mathrm{vac}}_{\Phi} + H^{\mathrm{vac}}_{\Theta}$, the *residual vacuum* energy density is

$$\rho_{\mathrm{DE}} := \frac{1}{\mathrm{Vol}(\mathcal{X}_q)} \Big\langle \overset{\circ}{\boldsymbol{\Psi}} \Big| \, \mathcal{P}^{\mathrm{sym}}_{\mathrm{vac}} \, H_{\mathrm{vac}} \, \mathcal{P}^{\mathrm{sym}}_{\mathrm{vac}} \, \Big| \overset{\circ}{\boldsymbol{\Psi}} \Big\rangle_{\mathrm{phys}} \equiv \varepsilon_{\Lambda},$$

a small, positive *interferometric residue* singled out by Stage II (Definition 13.93 and eq. (13.145)). This locks the DE lane to a projector-defined piece of the universal Hamiltonian rather than to a bare cosmological constant.

Dark matter (holosymmetric-projected). The dark-sector abundance is defined via the coherence projector $\mathcal{P}^{\mathrm{coh}}_{\mathrm{dark}}$, which selects gauges G that pass Stage I and remain spectrally orthogonal to SM observables; the resulting ρ_{DM} is the physically certified "dark" contribution (see Definition 13.94).

Visible sector. Analogously, $\mathcal{P}^{\mathrm{coh}}_{\mathrm{vis}}$ isolates the SM lane so that the standard spectral sum over SM eigenstates $\{|\psi_\beta\rangle, E_\beta\}$ defines ρ_{vis} within the same universal spectral calculus (cf. the discussion leading to ρ_{vis} after eq. (13.149)).

Cross-term bookkeeping (if leakage). If an imperfect sectoring/regulator produces a nonzero cross contribution $\delta_{\mathrm{cross}}(\lambda)$, the chapter introduces

$$\Omega_{\mathrm{cross}}(\lambda) := \frac{\delta_{\mathrm{cross}}(\lambda)}{\rho_{\mathrm{tot}}(\lambda)}, \qquad 1 = \Omega_{\mathrm{DE}} + \Omega_{\mathrm{DM}} + \Omega_{\mathrm{vis}} + \Omega_{\mathrm{cross}},$$

to keep normalization exact while one takes regulator-clean limits (after Definition 13.99).

Regulator independence (ratios). Crucially, *ratios* of abundances are invariant under comoving cell rescalings and foliation changes—$\mathrm{Vol}(\mathcal{X}_q)$ cancels—provided the BRST-physical projectors and the HSP filter are used. Hence Ω_i are regulator-independent predictions (Remark 13.96).

Route A (spectral-first) inputs. For practical inference, Route A specifies background-dressed dispersions $E_{\mathrm{geo}}(k), E_{\mathrm{tym}}(k)$, fixes a Planckian UV cutoff $\lambda_{\mathrm{cutoff}} = \ell_{\mathrm{P}} \Rightarrow k_{\mathrm{UV}} = \ell_{\mathrm{P}}^{-1}$, and IR cutoffs $k^{\mathrm{cos}}_{\mathrm{IR}} = H_0/c$ (with an optional local mass-gap IR where needed). These inputs let one compute $\rho_{\mathrm{tot}}(a)$ directly from the spectral data (Definition 13.134).

From $\rho_{\mathrm{tot}}(a)$ to distances and growth. On flat FLRW, the total density determines the dimensionless expansion rate via

$$E^2(a) = \frac{\kappa' c^2}{3H_0^2}\,\rho_{\mathrm{tot}}(a) = \frac{\rho_{\mathrm{tot}}(a)}{\rho_{\mathrm{tot}}(1)}, \qquad \kappa' = 8\pi G,$$

which plugs into the standard RW distance–redshift relations and linear-growth equation; curvature adds the familiar $\Omega_k a^{-2}$ term (Proposition 13.110 and Remark 13.111). Thus, the projector-resolved spectrum maps cleanly to late-time observables.

Two practical routes to numerical projectors. The chapter offers (i) a *constructive* SVD/eigendecomposition on GNS two-point Gram operators to realize $\mathcal{P}^{\rm coh}_{\rm vis}$ and $\mathcal{P}^{\rm coh}_{\rm dark}$ directly, and (ii) a *calibrated FLRW reduction* that fixes $\mathcal{P}^{\rm coh}_{\rm vis}$ and normalizes the dark projector to $\Omega_{\rm DM}(z{=}0)$ (procedure 13.139). Both routes preserve the holosymmetric normalization so that the abundance sum rule stays exact.

The temporal (τ–kairos) sector: DE, DM, and "dark gravity." The τ–lane is presented in three complementary branches that share the same chronogeometric placement and typed orthogonality with the TT sector.

Scalar (Gaiaton/Apeiron) branch. Relative to u^μ, the covariant fluid variables read

$$\rho_\varphi = \tfrac{1}{2}\dot\varphi^2 + \tfrac{1}{2}D^2\varphi + V, \quad p_\varphi = \tfrac{1}{2}\dot\varphi^2 - \tfrac{1}{6}D^2\varphi - V, \quad q_\mu = -\dot\varphi D_\mu\varphi, \quad \pi_{\mu\nu} = D_{\langle\mu}\varphi\, D_{\nu\rangle}\varphi,$$

and the field obeys the *relational KG* equation $\Box^{(\rm rel)}\varphi - V_{,\varphi} = 0$ with $\Box^{(\rm rel)} = \bar\Sigma^{\mu\nu}\nabla^{(\rm rel)}_\mu\nabla^{(\rm rel)}_\nu$ (eq. (13.94)). In the FLRW/comoving limit this reduces to $\rho_\varphi = \frac{1}{2}\dot\varphi^2 + V$, $p_\varphi = \frac{1}{2}\dot\varphi^2 - V$, giving $w_\varphi \simeq -1$ for slow-roll (Proposition 13.69). A shift symmetry yields the Noether current $J^\mu_\varphi = \nabla^{(\rm rel)\,\mu}\varphi$ with $\nabla^{(\rm rel)}_\mu J^\mu_\varphi = \Box^{(\rm rel)}\varphi = -V'(\varphi)$ (Proposition 13.81 and eq. (13.128)).

Vector (Chrono–Kymon, dark $U(1)_\tau$) branch. The gauge-invariant Stueckelberg/Higgsed *Noether current* is

$$J^\mu_\tau = \nabla^{(\rm rel)}_\nu\mathcal{H}^{\nu\mu} + \mu_C^2\left(K^{(\tau)\mu} - \frac{1}{\mu_C}\nabla^{(\rm rel)\,\mu}\theta\right),$$

which in unitary gauge becomes $J^\mu_\tau = \nabla^{(\rm rel)}_\nu\mathcal{H}^{\nu\mu} + \mu_C^2 K^{(\tau)\mu}$; with a dark Higgs, $J^\mu_\tau \mapsto J^\mu_\tau - j^\mu_{H_\tau}$ (Proposition 13.88 and eqs. (13.136) and (13.137)). On general backgrounds the Chrono–Kymon behaves like *cold DM*,

$$\langle w_{K^{(\tau)}}\rangle \simeq 0, \qquad \langle\dot\rho_{K^{(\tau)}}\rangle + \theta\,\langle\rho_{K^{(\tau)}}\rangle \simeq 0 \;\Rightarrow\; \rho \propto e^{-\int\theta\,dt},$$

and in FLRW this reduces to $\rho \propto a^{-3}$ (eq. (13.106) and Proposition 13.77). Typed TT isolation $\Pi^{[\rm TT]}_{\bar\Sigma}\hat\tau = 0$ guarantees *no extra GW polarizations*.

Macroscopic ("dark gravity") branch. A coherent τ–background shifts the diagnostic realized reference configuration geometry and the TT operator through *typed balance* relations,

$$\mathcal{L}_{hh}[\bar\Sigma'] = \mathcal{L}_{hh}[\bar\Sigma] + \varepsilon\,\delta\mathcal{L}_{hh}[\Delta\Sigma^{(\tau)}] + \cdots, \qquad \delta\bar G_{\mu\nu}[\Delta\Sigma^{(\tau)}] + \Lambda\,\Delta\Sigma^{(\tau)}_{\mu\nu} = \kappa\,\Delta\bar T^{(\tau)}_{\mu\nu},$$

thereby modifying the Einstein sector *without* introducing new spin-2 modes; microscopically, this is the same τ operator whose quanta produce particle-level dark matter (eq. (13.3) and surrounding text). The chapter also lists additional dark candidates—e.g., a massive/oscillatory Gaiaton (CDM-like) or slow-roll Gaiaton (DE-like) depending on the Hessian of $\mathcal{V}_\Phi$, and neutral spin-1 quanta from the universal connection $\mathcal{A}_\mu$ (Mition/Tantron)—see Candidate II & III for details.

Observable mass and the FLRW cross-check. Away from FLRW gauge, the *chronogeometric (quasilocal) mass* over a domain $\mathcal{D}_\tau$ with boundary S_τ is

$$M_{\rm obs}(\tau) = \frac{1}{c^2}\Big\langle\int_{\mathcal{D}_\tau}\sqrt{\gamma}\,\rho_{\rm tot}\,{\rm d}^3x\Big\rangle_{\rm phys} + \frac{c^2}{8\pi G}\Big\langle\oint_{S_\tau}(k-k_0)\,{\rm d}S\Big\rangle_{\rm phys},$$

which packages *bulk* (spectral energy) and *boundary* (extrinsic curvature) contributions into a single BRST-physical observable (Definition 13.155 and eq. (13.220)). For a homogeneous, flat domain at $a = 1$ this collapses to

$$M_{\rm obs} = \frac{H_0^2}{2G}\, R^3, \qquad \frac{\delta M}{M} \simeq 2\,\frac{\delta H_0}{H_0} + 3\,\frac{\delta R}{R},$$

providing a sharp FLRW *consistency check* (Remark 13.157). Predictively, one works with the *partition* $M_i = \Omega_i\, M_{\rm obs}$ (with $\sum_i \Omega_i = 1$) and with the background mapping $\Lambda_{\rm eff} = \Lambda + \kappa' \varepsilon_\Lambda$; beyond FLRW, deviations are precisely captured by the boundary term (same remark).

Chapter 13 welds the universal spectral definition of $\rho_{\rm tot}$ to a holosymmetric projector calculus that (i) cleanly partitions DE/DM/visible energy, (ii) carries through to FLRW distances and growth, and (iii) grounds both particle-like (CK/Gaiaton) and macroscopic ("dark gravity") phenomenology in a single τ–typed sector—while keeping every step anchored to Definitions 13.92 to 13.94, 13.134 and 13.155, eqs. (13.3), (13.94), (13.106), (13.128), (13.136), (13.137), (13.144), (13.145), (13.149), (13.150) and (13.220), Propositions 13.69, 13.77, 13.81, 13.97 and 13.110, Remarks 13.96, 13.111 and 13.157, and procedure 13.139.

The Cosmic symmetry stack. At cosmic scales the theory organizes fluctuations of the unified chronogeometric field into radiative spin-2 and temporal (τ–kairos) lanes. The diagnostic realized reference configuration/background and quantum fluctuations are split as

$$\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}, \qquad \delta\hat{\Sigma}_{\mu\nu} = \hat{h}_{\mu\nu} + \hat{\tau}_{\mu\nu},$$

together with the *typed* TT projection that isolates the spin-2 sector and nulls any TT leakage from the τ-lane,

$$\hat{h}_{\mu\nu} := \Pi_{\bar{\Sigma}}^{[\rm TT]}\, \delta\hat{g}_{\mu\nu}, \qquad \Pi_{\bar{\Sigma}}^{[\rm TT]}\hat{\tau}_{\mu\nu} = 0 \quad \text{(eq. (13.119))}.$$

The τ–sector itself is typed into scalar and vector registers,

$$\hat{\tau}_{\mu\nu} = S^{(b)}_{\mu\nu}[\hat{\varphi}_b] \oplus S^{(L)}_{\mu\nu}[\hat{\varphi}_L] \oplus \tilde{S}^{(p)}_{\mu\nu}[\tilde{\varphi}] \oplus \sum_{\lambda=\pm} A^{(\lambda)}_{\mu\nu}\left[\hat{K}^{(\tau)}_{\lambda}\right] \quad \text{(eq. (13.113))}.$$

This typed architecture fixes what counts as genuine spin-2 radiation ($\hat{h}_{\mu\nu}$) versus temporal dynamics ($\hat{\tau}_{\mu\nu}$), and it underlies every symmetry statement that follows.

2) Layer 1: Unified chronogeometry. The chronogeometric symmetries acting on $\delta\hat{\Sigma}_{\mu\nu}$ form the semidirect product

$$\boxed{\mathcal{G}_{\rm Chronogeom} := {\rm Diff}_{\rm rel}(\mathcal{X}_q) \;\ltimes\; \left({\rm SO}(1,3)_{\rm local} \;\times\; \mathcal{G}^{(\rm eff)}_{\rm Dark}\right)} \quad \text{(eq. (13.122))}.$$

Here ${\rm Diff}_{\rm rel}(\mathcal{X}_q)$ are relational diffeomorphisms on the diagnostic realized reference configuration $(\mathcal{X}_q, \bar{\Sigma})$, acting by pullback on fields and adjoint transport on internal fibers; ${\rm SO}(1,3)_{\rm local}$

are local Lorentz rotations; and $\mathcal{G}_{\rm Dark}^{(\rm eff)}$ is the *effective* symmetry badge governing the τ–kairos registers (not SM matter):

$$\boxed{\mathcal{G}_{\rm Dark}^{(\rm eff)} \supset \underbrace{\mathrm{Shift}_{\varphi_b} \times \mathrm{Shift}_{\varphi_L} \times \mathrm{Shift}_{\tilde{\varphi}}^{\rm ax}}_{\text{scalar shifts}} \times \underbrace{U(1)_\tau}_{\text{Chrono–Kymon phase}} \times \underbrace{U(1)_{\rm hel}}_{\text{helicity plane}} \times \underbrace{\mathbb{Z}_2^{\rm HS}}_{\text{HSP tag}}} \quad \text{(eq. (13.108)).}$$

The three Shift factors act on the breathing/longitudinal/axial scalars $(\varphi_b, \varphi_L, \tilde{\varphi})$; $U(1)_\tau$ is the Chrono–Kymon phase symmetry of the τ-vector $K^{(\tau)}$; $U(1)_{\rm hel} \simeq SO(2)$ rotates the helicity doublet $(K_+^{(\tau)}, K_-^{(\tau)})$; and $\mathbb{Z}_2^{\rm HS}$ labels holosymmetric (HSP) branch stability. All continuous factors are *effective* and may be softly broken by the same operators (masses, mixings, potentials) that drive cosmology.

Typed orthogonality. By construction the TT projector never "sees" τ–modes, and the typed projectors $\Pi^{[\chi]}$ (with $[\chi] \in \{b, L, p, \lambda = \pm\}$) commute appropriately. The identities summarized around eq. (13.115) guarantee the *absence of extra GW polarizations* and clean bookkeeping of scalar/vector contributions.

3) Layer 2: The full cosmic stack (add the Standard Model). The *cosmic* group multiplies chronogeometry with the SM gauge sector,

$$\boxed{\begin{aligned}\mathcal{G}_{\rm Cosmos} &= \underbrace{\mathcal{G}_{\rm Chronogeom}}_{\text{acts on } \delta\hat{\Sigma}_{\mu\nu}=\hat{h}_{\mu\nu}\oplus\hat{\tau}_{\mu\nu}} \times \underbrace{G_{\rm SM}}_{\text{Tantrakyma (matter/gauge)}} \\ &= \left[\mathrm{Diff}_{\rm rel} \ltimes \left(\mathrm{SO}(1,3)_{\rm local} \times \mathcal{G}_{\rm Dark}^{(\rm eff)}\right)\right] \times \left[SU(3)_C \times SU(2)_L \times U(1)_Y\right],\end{aligned}}$$

as summarized in the chapter's "cosmic symmetry stack (summary)" (Section 13.4.1). The direct product with $G_{\rm SM}$ reflects that SM fields ("Tantrakyma") live on the chronogeometric background yet carry their *own* internal gauge charges.

The placement of the symmetry structures is *chronogeometric* in the strict sense (Section 13.4.1): the stack is organized on the chronogeometric fiber itself—namely, on the unified fluctuation $\delta\hat{\Sigma}$—rather than as an external juxtaposition "SM+GR". Concretely, spin-2 radiation is confined to the $\hat{h}_{\mu\nu}$ lane by the typed projector $\Pi^{[\rm TT]}$; all *temporal* physics (dark energy, dark matter, and "dark gravity" responses) inhabits the τ-lane with its own effective symmetries and soft breakings; and diffeomorphisms act *semidirectly* ($\ltimes$) because they simultaneously move fields on $\mathcal{X}_q$ and rotate the local fiber.

Operationally, the stack is not merely kinematical but the stage on which *holosymmetric tomography* and the *Holosymmetric Selection Principle (HSP)* operate. Stage I (safety) enforces BRST-physicality and typed/TT constraints, fixing the admissible set; Stage II (selection) then chooses, within that set, the background that maximizes holosymmetric coherence under SM-orthogonality (the HSP overlap rule) (Sections 13.1.3 and 13.1.4). This adjudication typically selects (i) a CK (Chrono–Kymon) branch with $\langle w_{K^{(\tau)}} \rangle \simeq 0$ and cosmic scaling $\rho \propto a^{-3}$ (cold-DM–like; cf. eq. (13.106) and Proposition 13.77), and/or (ii)

a scalar Gaiaton/Apeiron branch with slow roll $w_\varphi \simeq -1$ (DE-like), all while maintaining $\Pi^{[\mathrm{TT}]}$-orthogonality (no extra spin-2 modes) and compatibility with SM phenomenology.

Three consistency checks frame the construction. First, *GW consistency*: typed TT-null identities prevent extra gravitational-wave polarizations from the τ-sector; only $\hat{h}_{\mu\nu}$ propagates as spin-2 (see eqs. (13.115) and (13.119)). Second, *Modular/KMS alignment*: in stationary regimes (e.g. horizons), the time emerging from the universal constraint and internal clocks aligns with modular/KMS structure along the same symmetry lanes. Third, *soft breaking = cosmology*: the operators that softly break $\mathcal{G}_{\mathrm{Dark}}^{(\mathrm{eff})}$ (masses, potentials, mixings) are precisely those that yield late-time DE/DM phenomenology, tying the kinematics of the stack to macro-cosmic dynamics.

In practice, the stack *organizes projectors* and resolves the universal Hamiltonian's spectrum into DE/DM/visible contributions, leading to the abundance partition that feeds Ω_i and thus to observable distances and growth. It *guarantees regulator independence* of abundance ratios by preserving the TT/typed/HSP structure. Finally, it *bridges micro* $\leftrightarrow$ *macro*: the same τ-sector whose quanta realize particle-level dark matter (CK) also induces coherent background shifts ("dark gravity") in the diagnostic realized reference configuration equations without introducing new spin-2 degrees (eq. (13.3)).

$$\boxed{\mathcal{G}_{\mathrm{Cosmos}} = \left[\mathrm{Diff}_{\mathrm{rel}} \ltimes (\mathrm{SO}(1,3)_{\mathrm{local}} \times \mathcal{G}_{\mathrm{Dark}}^{(\mathrm{eff})})\right] \times G_{\mathrm{SM}}}$$

is placed *on* the chronogeometric fiber with typed TT-orthogonality and the effective dark badge (Shift $\times\, U(1)_\tau \times U(1)_{\mathrm{hel}} \times \mathbb{Z}_2^{\mathrm{HS}}$); operationally, HSP prunes/realizes this skeleton to produce the DE/DM/visible trichotomy used throughout Chapter 13 (Section 13.4.1 and eqs. (13.113) and (13.119)).

Universal Quantum Constraint: statement and setting. In the certified BRST-physical realized weave configuration of Chapter 13, the realized Holo–State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle \in \mathcal{H}_{\mathrm{phys}}$ is annihilated by the total (relational) Hamiltonian,

$$\boxed{\hat{H}_{\mathrm{univ}}\,|\overset{\circ}{\boldsymbol{\Psi}}\rangle = 0} \qquad \text{(Thm. Theorem 13.168)},$$

with

$$\hat{H}_{\mathrm{univ}} = \hat{H}_\Phi + \hat{H}_\Theta + \hat{H}_{\mathrm{int}} \qquad \text{(Def. Definition 13.167)}.$$

This pins down the UQC as an *operator* constraint rather than a mere scalar energy condition, and it is posed directly on $\mathcal{H}_{\mathrm{phys}}$ so that all equalities are taken between BRST-physical states.

Why a constraint: the timeless thesis. Time in Chapter 13 is *relational*, not a fixed background parameter. Consequently, cosmic dynamics is cast in the Dirac/Wheeler–DeWitt spirit as a *single* quantum constraint on the universal state. Subsystem dynamics is then recovered by conditioning on good internal clocks and gauges (the chronogeometric placement ensures that such clocks live in the typed τ-lanes; see eqs. (13.115) and (13.119) for the TT/τ split that protects reparametrization invariance).

Ward-identity route (core proof step). Beginning with the adjoint-covariant Ward identity for time-reparametrizations, the source term decomposes into controlled deformations, BRST-exact pieces, and potential anomalies. On the certified operator realized weave configuration used in the chapter, BRST-exact contributions drop between physical states, Stage-I viability drives anomaly meters to zero, and calibrated boundary terms cancel. The net result is constancy of the total time-translation charge,

$$\dot{\mathbf{Q}}_{(t)} = 0, \qquad \Rightarrow \qquad \mathbf{Q}_{(t)} = \text{const.}$$

Under the universal closed calibration adopted for the cosmological background, $\mathbf{Q}_{(t)}$ is fixed to zero, which furnishes the bridge to the operator equation below.

From charge constancy to the operator law. With chronogeometric placement and typed TT-orthogonality, the clock-capable τ-lanes cannot induce explicit time-reparametrization breaking. Hence the universal evolution operator

$$U(s) = \exp\!\left(-\frac{i}{\hbar}\, s\, \hat{H}_{\text{univ}}\right)$$

leaves the universal state invariant, $U(s)\,|\overset{\circ}{\mathbf{\Psi}}\rangle = |\overset{\circ}{\mathbf{\Psi}}\rangle$. Differentiating at $s = 0$ yields the UQC in operator form,

$$\hat{H}_{\text{univ}}\,|\overset{\circ}{\mathbf{\Psi}}\rangle = 0 \qquad \text{(Thm. Theorem 13.168)}.$$

The role of the cosmic symmetry stack. The symmetry skeleton $\mathcal{G}_{\text{Cosmos}} = \left[\text{Diff}_{\text{rel}} \ltimes (\text{SO}(1,3)_{\text{local}} \times \mathcal{G}^{(\text{eff})}_{\text{Dark}})\right] \times G_{\text{SM}}$ (cf. Section 13.4.1) does not alter the content of the UQC; it *tightens* its hypotheses. Lane-wise BRST cleanliness, TT-nullity (eq. (13.119)), and a canonical clock sector ensure anomaly freedom and make the Ward argument above modular: each typed lane respects reparametrization invariance, so the combined system does as well, and the constraint holds exactly on $\mathcal{H}_{\text{phys}}$.

Dirac/BRST equivalence. Time-reparametrization invariance implies a first-class Hamiltonian constraint at the canonical level. In BRST quantization this lifts to an operator condition on physical states. The chapter's universal formulation matches this structure precisely, reproducing

$$\hat{H}_{\text{univ}}\,|\overset{\circ}{\mathbf{\Psi}}\rangle = 0$$

as the BRST-physical condition for the cosmological state, in agreement with Thm. Theorem 13.168.

Operational meaning. The UQC asserts that the *total relational energy vanishes*: the realized cosmos is a stationary, entangled Holo–State. What we ordinarily call "time'' appears only as a relational parameter extracted from internal clocks or (in stationary sectors) from modular/KMS flows. This same law underwrites the chapter's horizon-thermodynamic and cosmological applications, since it anchors all energetics to a constraint—rather than to an external time evolution.

Emergent Schrödinger dynamics for parts. Given a good internal clock and a BRST-physical factorization $\mathcal{H}_{\text{phys}} = \mathcal{H}_{\text{sub}} \otimes \mathcal{H}_{\text{clock}}$, conditioning the timeless state on clock readings produces unitary subsystem evolution with an effective Hamiltonian,

$$|\psi(t)\rangle := \frac{\langle t|\overset{\circ}{\mathbf{\Psi}}\rangle}{\|\langle t|\overset{\circ}{\mathbf{\Psi}}\rangle\|} \qquad \Longrightarrow \qquad i\hbar\,\partial_t|\psi(t)\rangle = \hat{H}_{\text{sub}}\,|\psi(t)\rangle,$$

compatible by construction with the UQC (see the post-theorem discussion around Thm. Theorem 13.168).

Spectral resolution and the abundance partition (after UQC). With the BRST-clean, lane-resolved $\hat{H}_{\text{univ}}$ and calibrated boundaries, the comoving total energy density is given by the spectral measure of $\hat{H}_{\text{univ}}$,

$$\begin{aligned}\rho_{\text{tot}} &= \frac{1}{\text{Vol}(\mathcal{X}_q)} \Big\langle \overset{\circ}{\boldsymbol{\Psi}} \Big| \hat{H}_{\text{univ}} \Big| \overset{\circ}{\boldsymbol{\Psi}} \Big\rangle_{\text{phys}} \\ &= \frac{1}{\text{Vol}(\mathcal{X}_q)} \int_{\sigma(\hat{H}_{\text{univ}})} E \, \mathrm{d}\mu_{\overset{\circ}{\boldsymbol{\Psi}}}^{\hat{H}_{\text{univ}}}(E) \quad (\textit{Definition 13.92and eq. (13.144)}),\end{aligned}$$

and, when holosymmetric projectors resolve the identity, it partitions as

$$\rho_{\text{tot}} = \rho_{\text{DE}} + \rho_{\text{DM}} + \rho_{\text{vis}},$$
$$\Omega_i = \frac{\rho_i}{\rho_{\text{tot}}}, \quad \sum_i \Omega_i = 1 \quad (\textit{Proposition 13.97and eqs. (13.149)and (13.150)}).$$

Summary arc.

Chapter 14: The Born Rule and Measurement

Chapter 14 reframes "measurement" as a local enactment of a universal, holosymmetric logic rather than an ad-hoc rupture of quantum dynamics. The narrative begins with the staged pipeline Evolve → Interfere → Re-evolve that is implemented by the holosymmetric interferometer (Section 3.1 and Definitions 2.123 and 3.12). System–apparatus coupling first creates robust entanglement and then decoheres into the environment, while classical definiteness is read as the Axiom of Duality's Boolean slice of an underlying fourfold logic (Section 14.1.3, Axiom 1.10, Definition 1.5, and Proposition 1.8). In this account, wave/particle duality is resolved as two faces of one process: an unobserved state inhabits the parasymmetric, superpositional stratum ($|\Psi_{\text{fin}}\rangle = \sum_k c_k \, |s_k\rangle \, |a_k\rangle \, |e_k\rangle$ with lane orthogonality; eq. (14.37)), while observation is a path-scattering "interference event" whose decohering broadcast into the Gaiamiti background leaves a locally classical record (Sections 14.1.3 and 14.3.1). Measurement thus becomes the localized instance of the Holosymmetric Selection Principle's global choice of laws: the same interferometric architecture that picks a self-coherent universe also governs the "click of a single detector" (Sections 13.2.7 and 14.1.1).

Program for the Born rule. Against this backdrop the chapter turns to probability. It first acknowledges standard practice—using the Born rule axiomatically for holosymmetric

effects E via $v(\rho; E) = \mathrm{Tr}(\rho E)$ in the interferometer/path-scattering models (Definitions 1.18 and 1.34, Corollary 3.3, and eq. (3.1))—before launching a three-stage derivation program (Sections 14.2, 14.2.1 and 14.2.2). *Stage 1* models measurement as relational decoherence that produces an orthogonal pointer basis for outcomes (preparation and imprint: eqs. (14.11) and (14.12); orthogonality at readout: Section 14.3.1 and eq. (14.37)). *Stage 2* uses relational envariance on the parasymmetric stratum—phase indifference, swap symmetry, and ancilla fine-graining—to fix

$$p_k = f(|c_k|) = |c_k|^2,$$

(phase indifference eq. (14.39), equiprobability eq. (14.4) and Lemma 14.9, fine-graining eq. (14.42); cf. eq. (14.43)).

Equivalently, probability is identified with the emergent inner-product norm of each branch, using the Fourfold Inter–Modal Correlator to define $\langle\cdot\rangle\cdot$ (eq. (14.38) and Section 14.3.2). *Stage 3* proves uniqueness from dialectic/monoidal constraints on the Axiom-of-Duality slice—additivity on orthogonal joins, unitary covariance, product factorization, coarse-graining noncontextuality, and continuity—together with Monoidal Duality's multiplicativity $f(rs) = f(r)f(s)$, which (with equiprobability) fixes the quadratic rule for all projectors (Section 14.3.3, Lemma 14.10, and Theorems 14.3, 14.4 and 14.11). In parallel, global-to-local consistency with the Universal Quantum Constraint—implemented by Page–Wootters conditioning with a good clock—excludes non-quadratic exponents on conservation grounds when time is emergent (Theorem 13.168, eqs. (13.227) and (13.236), Definition 13.158, Proposition 13.162, Corollary 13.163, and Sections 14.2.2 and 14.3.3). Holosymmetric Selection further prunes any non-Born assignments by diagnostic "twist" in commutator-lensing (Sections 13.2.7 and 14.3.3). The upshot is the explicit theorem: probabilities equal relational self-coherences,

$$p_k = \langle\Psi_{\mathrm{fin}}|\, P_k\, |\Psi_{\mathrm{fin}}\rangle = |c_k|^2, \qquad \text{with } P_k = \mathbb{I}_S \otimes |a_k\rangle\langle a_k| \otimes \mathbb{I}_E \text{ at readout (eq. (14.45)).}$$

No circularity: two-tier semantics at a fixed point. Finally, the chapter resolves the apparent circularity by distinguishing a pre-probabilistic state-valuation $v_0(E) = \omega(E)$, which Holosymmetry uses to build interferometric/lensing readouts (Definition 14.13 and Proposition 14.15), from operational probabilities. Stages 2–3 then prove that any calibration-compatible reparametrization $p = g \circ v_0$ collapses to the identity $g(x) = x$ (fixed-point identification), so Born-valued truths and Born probabilities coincide numerically without being conceptually conflated (Definition 14.14, Proposition 14.16, Theorem 14.19, Section 14.3.4, and Corollary 14.8). This fixed-point identification is background-independent—relying only on the effect algebra, the BRST/GNS state, and the universal constraint—and it seals the reflective consistency of the whole edifice: Tetralemma of Algebra + Duality + Holosymmetry together (under UQC) select the quadratic rule as the unique semantics of empirical frequency in an interdependent quantum reality (Definition 1.5, Axiom 1.10, Section 3.1, and Theorem 13.168).

Formal synthesis. The chapter's synthesis states that the combined force of the Tetralemma, Duality, Holosymmetry, and the Universal Quantum Constraint (UQC) determines the Born rule on the outcome stratum:

$$\boxed{\text{Tetralemma} + \text{Duality} + \text{Holosymmetry} + \text{UQC} \implies p_k = \langle\Psi_{\mathrm{fin}}|\, P_k\, |\Psi_{\mathrm{fin}}\rangle = |c_k|^2}.$$

In the emergent/GNS semantics, probabilities are *Born valuations* $v(\rho;E) = \mathrm{Tr}(\rho E)$ of holosymmetric effects (Definitions 1.18 and 1.34). Inner products are not primitive but derived from the Fourfold Inter–Modal Correlator via the emergent inner product (see eq. (14.38) and Ch. 4 for correlator-induced overlaps and triadic distances).

Holosymmetric interferometer (laboratory avatar of HSP). The holosymmetric interferometer provides the operational avatar of the HSP selection logic. With control basis $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$ steering the dual radiant registers, the controlled block is

$$\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \quad \text{(eqs. (3.47) and (3.48))}.$$

The symmetric device is $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})} := \mathbf{U}_{\mathrm{Had}}\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{Had}}$ (Definition 2.123); its tomographic/asymmetric generalization uses arbitrary $\mathbf{U}_{\mathrm{prep}}, \mathbf{U}_{\mathrm{read}} \in \mathrm{SU}(2)$,

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{asym})} := \mathbf{U}_{\mathrm{read}}\ \mathbf{U}_{\mathrm{ctrl}}\ \mathbf{U}_{\mathrm{prep}} \quad \text{(Section 3.1)}.$$

For the symmetric device, the bright-port probability for input $|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle$ is

$$p_0 = \tfrac{1}{4}\left\|(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})\,|\Psi_{\mathrm{RR}}\rangle\right\|^2 \quad \text{(Corollary 3.3 and eq. (3.1))}.$$

The *commutator lens* emphasizes that fringes are commutators in disguise,

$$[\mathbf{U}_{\mathrm{Had}}, \mathbf{U}_{\mathrm{ctrl}}] = \tfrac{1}{\sqrt{2}}\begin{pmatrix} 0 & \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \\ \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} & 0 \end{pmatrix} \quad \text{(Definition 3.12)},$$

so postselecting $|\mathbf{0}\rangle_c$ yields

$$|\Psi_{\mathrm{post}}\rangle = \frac{\hat{\mathbf{U}}_+\,|\Psi_{\mathrm{RR}}\rangle}{\|\hat{\mathbf{U}}_+\,|\Psi_{\mathrm{RR}}\rangle\|}, \qquad \hat{\mathbf{U}}_+ := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.$$

Measurement as path-scattering: Evolve → Interfere → Re-evolve. A laboratory measurement enacts the HSP-selected rules via the holosymmetric pipeline Evolve→Interfere→Re-evolve, with controls/readouts on the dual registers; conditioning on a control outcome initiates the re-evolve stage (Section 3.1). The separable preparation and local imprint are

$$|\Psi_{\mathrm{initial}}\rangle = \Big(\sum_i c_i\,|s_i\rangle\Big) \otimes |a_0\rangle \otimes |e_0\rangle, \qquad \sum_i |c_i|^2 = 1 \quad \text{(eq. (14.11))},$$

followed by a controlled imprint $U_{SA} : |s_i\rangle|a_0\rangle \mapsto |s_i\rangle|a_i\rangle$, producing $|\Psi_{\mathrm{ent}}\rangle = \sum_i c_i|s_i\rangle|a_i\rangle|e_0\rangle$ (eq. (14.12)). A perfectly correlating imprint is realized by the effective controlled Hamiltonian

$$\boxed{\hat{H}_{SA}^{\mathrm{eff}} = \sum_i |s_i\rangle\langle s_i| \ \otimes\ \hat{h}_i, \quad \hat{h}_i = \frac{\Omega_i}{2}\Big(|a_i\rangle\langle a_0| + |a_0\rangle\langle a_i|\Big)} \quad \text{(eq. (14.24))}.$$

Coupling the apparatus to the environment drives global decoherence; descending from a bi-local interaction action, it is presented as

$$\boxed{\hat{H}_{AE} := g_{AE}\int d^d x'\ \mathrm{Tr}\Big[\hat{\mathbf{\Phi}}_E^\dagger(x')\,\mathcal{U}_{\Phi\Theta}(x', x_A)\,\hat{\mathbf{\Theta}}_A(x_A)\Big]} \quad \text{(eqs. (14.13) and (14.29))}.$$

Born valuation at readout and the decoherence mechanism. In the minimal "measurement as relational entanglement'' cartoon,

$$\hat{U}_{\text{int}}\Big(\sum_i c_i|s_i\rangle \otimes |A_0\rangle\Big) = \sum_i c_i\,|s_i\rangle \otimes |A_i\rangle,$$
$$p_i = \langle\Psi_{\text{fin}}|(\mathbf{1}\otimes P_i)|\Psi_{\text{fin}}\rangle = |c_i|^2 \quad (\textit{Section 14.1.2and eq. (14.45)}).$$

With environment E,

$$|\Psi_{\text{SAE}}\rangle = \sum_i c_i\,|s_i\rangle \otimes |A_i\rangle \otimes |E_i\rangle, \quad \rho_S = \sum_i |c_i|^2 |s_i\rangle\langle s_i| + \sum_{i\neq j} c_i c_j^*\,\langle E_j|E_i\rangle\,|s_i\rangle\langle s_j|,$$

so as $\langle E_j|E_i\rangle \to 0$ the off-diagonals die out; the Ch. 4 triad $(d_{\text{corr}}, d_{\text{vac}}, d_{\text{spec}})$ explains this suppression and the emergence of effective classicality under coarse-graining (cf. Section 14.3.1).

Duality and the Twofold readout. By the *Axiom of Duality*, communicable outcomes inhabit a Twofold subspace with orthonormal basis $\{|\mathring{\mathbf{0}}\rangle, |\mathring{\mathbf{1}}\rangle\}$ and projectors $P_{\mathbf{0}}, P_{\mathbf{1}}$ satisfying $P_{\mathbf{0}} + P_{\mathbf{1}} = \mathbf{1}_{\text{Twofold}}$ and $P_{\mathbf{0}}P_{\mathbf{1}} = 0$; the classical outcome "$\mathbf{0/1}$" is then the Born valuation $p_{\mathbf{i}} = \text{Tr}(\rho P_{\mathbf{i}})$ (Section 14.1.3 and Axiom 1.10). On this AD slice, an admissible probability functional must obey additivity on orthogonal joins, unitary covariance, product factorization, coarse-graining noncontextuality, and continuity (Section 14.3.3). In particular, *Monoidal Duality* imposes multiplicativity on products (Lemma 14.10), which for rank-1 branches yields $f(rs) = f(r)f(s)$ and, by continuity, $f(r) = r^\alpha$; equiprobability for n equal branches fixes $\alpha = 2$. Thus the Stage-2 branch rule extends to *all* projectors:

$$p(P \mid \psi) = \langle\psi|\,P\,|\psi\rangle \quad \text{(Theorems 14.3, 14.4 and 14.11)}.$$

UQC and conditional dynamics. All laboratory conditioning sits inside the *Universal Quantum Constraint*

$$\boxed{\hat{H}_{\text{univ}}\Big|\mathring{\mathbf{\Psi}}\Big\rangle = 0}, \qquad \hat{H}_{\text{univ}} = \hat{H}_\Phi + \hat{H}_\Theta + \hat{H}_{\text{int}} + \hat{H}_\partial \quad \text{(Theorem 13.168 and eq. (13.236))}.$$

Deparametrizing with a good clock C (Stone-covariant PVMs $\{\Pi_t\}$) yields the conditioned state

$$\varrho_{\text{sub}|t} = \frac{\Pi_t\,\varrho\,\Pi_t}{\text{Tr}(\Pi_t\varrho)} \quad \text{(PVM)}; \quad \text{POVM via Naimark/Kraus (Corollary 13.163)}.$$

On certified plateaues $\mathfrak{P}$, the PVM case gives unitary conditional dynamics

$$i\hbar\,\partial_t\,|\Psi_{\text{sub}}(t)\rangle = \hat{H}^{\text{eff}}_{\text{sub}}(t)\,|\Psi_{\text{sub}}(t)\rangle\,,$$
$$\hat{H}^{\text{eff}}_{\text{sub}}(t) = \hat{H}_{\text{sub}} + \langle t|\,\hat{H}_{\text{int}}\,|t\rangle \quad (\textit{Proposition 13.162and eq. (13.227)}),$$

while the POVM case adds a small dissipator $i\hbar\,\mathcal{D}_t[\cdot] \to 0$ in the sharp limit (Corollary 13.163). Good-clock hygiene ensures $[A, \Pi_t] = 0$ for $A \in \mathcal{A}$ and TT-nullity (Definition 13.158 and Lemma 13.161), so the AD axioms (product, covariance) and Tetralemma coarse-graining logic apply unchanged to $\varrho_{\text{sub}|t}$.

Cosmic stack and typed cleanliness. On BRST-physical diagnostic realized reference configuration the symmetry stack

$$\mathcal{G}_{\text{Cosmos}} = \Big[\text{Diff}_{\text{rel}} \ltimes (\text{SO}(1,3)_{\text{local}} \times \mathcal{G}^{(\text{eff})}_{\text{Dark}})\Big] \times G_{\text{SM}}$$

acts on $\delta\hat{\Sigma}_{\mu\nu} = \hat{h}_{\mu\nu} \oplus \hat{\tau}_{\mu\nu}$ with typed TT-orthogonality; BRST-physical projectors split vacuum/dark/visible lanes via $\mathcal{P}^{\text{sym}}_{\text{vac}} + \mathcal{P}^{\text{coh}}_{\text{dark}} + \mathcal{P}^{\text{coh}}_{\text{vis}} = \mathbf{1}_{\text{phys}}$. This typed hygiene is what keeps the measurement template well-posed and TT-clean (cf. Section 14.3.3).

Putting the synthesis to work. On the Parasymmetric (synthesis) stratum the post-measurement state is lane-orthogonal,

$$|\Psi_{\text{fin}}\rangle = \sum_k c_k \, |s_k\rangle\,|a_k\rangle\,|e_k\rangle\,, \qquad \langle a_k\rangle\, a_\ell = \delta_{k\ell}, \quad \langle e_k\rangle\, e_\ell \approx \delta_{k\ell} \quad (\textit{eq. (14.37)}),$$

and Parasymmetric automorphisms together with environment-assisted invariance yield: phase indifference $p_k = f(|c_k|)$ (Section 14.2.2 and eq. (14.39)); swap-envariance/equiprobability on equal-modulus branches (eq. (14.4) and Lemma 14.9); and ancilla fine-graining that, for rational weights $|c_k|^2 = r_k/N$, gives $p_k = r_k/N = |c_k|^2$, extended by continuity to all amplitudes,

$$\boxed{p_k = |c_k|^2} \quad \text{(Stage 2; eq. (14.43))}.$$

Holosymmetry provides the operational preparation (pointer orthonormality), the projector reading, and the dynamical suppression of non-Born alternatives through commutator-lensing diagnostics (Sections 13.2.7 and 14.3.3). Duality (AD) imposes the Boolean outcome layer and composition axioms; Monoidal Duality enforces multiplicativity, which—together with equiprobability—fixes the unique quadratic rule for all projectors,

$$p(P \mid \psi) = \langle\psi|\, P\, |\psi\rangle \quad (\textit{Theorems 14.3, 14.4 and 14.11}).$$

Finally, UQC and Page–Wootters conditioning tie local valuations to globally conserved expectations; non-quadratic rules violate this consistency and are thus excluded (Sections 14.3.3 and 14.3.4). Equivalently, probability equals the *relational self-coherence* computed with the emergent inner product (Section 14.3.2):

$$p_k = \langle\Psi_{\text{fin}}|\, P_k\, |\Psi_{\text{fin}}\rangle = |c_k|^2.$$

Good–clock bridge. Deparametrizing the UQC with a good clock C (Definition 13.158) ensures gauge-clean, TT-safe conditioning and supplies the bridge identity for measurements in the $\{|s_k\rangle\}$ basis at time t,

$$\boxed{p_k(t) = \text{Tr}\Big(\varrho_{\text{sub}|t}\ |s_k\rangle\langle s_k|\Big) = |c_k(t)|^2}\,,$$

with POVM-clock corrections $i\hbar\,\mathcal{D}_t[\cdot] \to 0$ in the sharp limit (Corollary 13.163). This shows that Holosymmetry, Duality, and the Tetralemma act on the conditioned state exactly as required to deliver the Stage-2/3 Born rule on certified plateaues, completing the synthesis.

Chapter 15: Quantum Thermodynamics

hapter 15 derives the thermodynamic laws inside the IQR framework by starting from a C*-algebraic foundation on the PQS continuum $\mathcal{X}_q$, where the global Quantum Holo-State $\omega^{\mathring{\mathbf{\Psi}}}$ selects its GNS realisation and thereby fixes the Emergent Hilbert Space $\mathcal{H}_{\text{em}}$ together with subsystem algebras $\mathcal{A}_X \subset \mathcal{A}(\mathcal{C}_d)$ (Definitions 1.32 and 4.287 and Sections 1.4 and 1.4.1) [30, 22]. In this representation-theoretic setting, conserved Noether currents and charges are handled at the algebraic level and tied to the relational Hamiltonian structure (Sections 15.1, 15.1.1 and 15.1.3) [52, 117]. "Equilibrium'' is inherently relational: it is the stationarity of the restricted state on a chosen subalgebra together with vanishing net conserved current between subsystems, formulated within the unified causal architecture fixed by the expectation-level chronogeometry $\bar{\Sigma}$ and Good-clock gauge class $[C]$ (Definitions 5.26, 5.150 and 13.158) [119, 20, 45]. In this light, the Zeroth Law is shown to be a theorem of algebraic self-consistency on the universal state—an informational transitivity statement rather than a bare postulate—obtained by projection to the physical cohomology and by enforcing Σ-causal support (Section 15.1.2, Theorem 15.7, and Corollary 5.145) [30, 22, 119, 40].

> Equilibrium between two $\bar{\Sigma}$-causally connected *and interacting* subsystems X and Y—with $\bar{\Sigma}_{\mu\nu}(x) := \omega^{\mathring{\mathbf{\Psi}}}\big(\hat{\Sigma}_{\mu\nu}(x)\big) = \big\langle \Omega_\omega \big| \, \pi_\omega\big(\hat{\Sigma}_{\mu\nu}(x)\big) \, \big| \Omega_\omega \big\rangle$—is a dynamical alignment of their joint algebra $\mathcal{A}_X \vee \mathcal{A}_Y$. It is defined by two predicates on their shared, $\hat{G}_\Lambda$–based statistics *evaluated with the emergent inner product*: (1) **stationarity** under the Good-clock flow on $\mathcal{A}_X \vee \mathcal{A}_Y$, $\partial_t \langle O \rangle_{XY} = 0$ for all $O \in \mathcal{A}_X \vee \mathcal{A}_Y$; and (2) **vanishing of the relational Noether current** between X and Y, expressed componentwise for the fundamental fields as
>
> $$\Big\langle \hat{J}^\mu_{\mathbf{\Phi}}(X) - \hat{J}^\mu_{\mathbf{\Phi}}(Y) \Big\rangle = 0, \qquad \Big\langle \hat{J}^\mu_{\mathbf{\Theta}}(X) - \hat{J}^\mu_{\mathbf{\Theta}}(Y) \Big\rangle = 0,$$
>
> where $\hat{J}^\mu_{\mathbf{\Phi}}$ and $\hat{J}^\mu_{\mathbf{\Theta}}$ are the $\hat{\mathbf{\Phi}}$-Gaiamiti and $\hat{\mathbf{\Theta}}$-Tantrakyma Noether currents, respectively.

Building on this foundation, the First Law is reimagined by explicitly decomposing the total dynamics into coherent transport and interaction-induced monitoring [22, 30]. The current–kernel interaction $\hat{H}_{AE}$ and the record (pointer) channel $\mathbb{E}_A$ (Definitions 15.25 and 15.27) yield a stroboscopic reduced evolution whose coherent part is unitary while incoherent exchange is captured by unital pinching on the record algebra [22, 30]. Identifying local energy change with interaction-driven exchange then gives the diagnostic realized reference configuration-wise balance $\Delta U_A = Q - W$ from the Heisenberg evolution of the subsystem within a conserved total energy, now interpreted relationally (Section 15.1.3, eq. (15.12), Theorem 15.18, and Definition 15.14) [119].

The Second Law appears as an H-theorem for Page–Wootters–conditioned, coarse-grained dynamics: the CP–divisible product-limit generator on the state-conditioned active band enforces entropy monotonicity $S_A(t)$ via pinching/majorisation arguments, with equality only when the state resides on the record algebra and the instantaneous motion there is unitary (Propositions 13.172, 15.31 and 15.41, Definitions 15.27, 15.37 and 15.56, Assumption 15.39, Lemma 15.30, Theorem 15.50, eq. (15.14), and Corollary 15.48) [22, 30, 119].

Finally, the Third Law is recast as *asymptotic coherence*: as the relational coupling $g \downarrow 0$, GKLS rates vanish and the reduced dynamics tends to a unitary group so that entropy production flattens; exact isolation (the analogue of $T{=}0$) is unattainable at any finite Good-clock time, in harmony with resource-bounded control limits and purity lower bounds (Section 15.1.5, Propositions 15.52 and 15.62, and Theorem 15.65) [119, 137, 47, 48]. The chapter distinguishes the PQS both as the asymptotic ideal for laboratory subsystems and as a gravitationally realised but operationally inaccessible limit (consistent with the two-level applicability domain and the Planck floor), thereby preserving unattainability while situating thermodynamics as relational information dynamics throughout (Definitions 15.54 and 15.55 and Corollary 15.63) [40, 42, 20].

Foundational arena and measurement semantics. The operational stage is the PQS continuum $\mathcal{X}_q$ equipped with the C*-algebra of relational observables $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32). A coherent Quantum Holo-State $\omega^{\mathring{\mathbf{\Psi}}}$ selects the GNS representation, yielding the Emergent Hilbert Space $\mathcal{H}_{\mathrm{em}}$ and the vector state $|\mathring{\mathbf{\Psi}}\rangle$ (Sections 1.4 and 1.4.1 and Definition 4.287). Subsystems are subalgebras $\mathcal{A}_X \subset \mathcal{A}(\mathcal{C}_d)$ with restricted states ω_X, and probabilities are assigned by the Born valuation

$$v(\rho; E) = \mathrm{Tr}(\rho E) \qquad \text{(Definition 1.18)}.$$

The A–E interface: current–kernel coupling and pointer channel. Matter–geometry exchange is governed by the current–kernel interaction Hamiltonian

$$\hat{H}_{AE} := \int_{\mathcal{X}_q} \mathrm{d}x\, \mathrm{d}x'\ \mathrm{Tr}\Big[\hat{J}^{\Phi}_{(\Theta)}(x)\, \mathcal{U}_{\Phi\Theta}(x,x')\, \hat{J}^{\Theta}_{(\Phi)}(x')\Big],$$

with $\mathcal{U}_{\Phi\Theta}$ transported along $\bar{\Sigma}$-chronogeodesics (Definition 15.25). In the einselection regime the record (pointer) algebra on A admits orthogonal projectors $\{P_k\}_k$ and induces the Relational pointer channel

$$\mathbb{E}_A(\rho) := \sum_k P_k\, \rho\, P_k,$$

which is CPTP, idempotent, unital, and transport-covariant (Definition 15.27). A stroboscopic reduced step of size Δt combines unitary transport with einselection,

$$\Phi_{\Delta t}(\rho) := \mathbb{E}_A\Big(U_A(\Delta t)\, \rho\, U_A(\Delta t)^\dagger\Big), \qquad U_A(\Delta t) = e^{-iH_{A,\mathrm{eff}}\Delta t},$$

so unitary conjugation preserves spectral entropy and entropy production is due solely to $\mathbb{E}_A$.

Pinching increases entropy (engine of the H–theorem). Because $\mathbb{E}_A$ is a pinching onto the commutative record algebra,

$$S\Big(\mathbb{E}_A(\rho)\Big) \ \geq\ S(\rho), \qquad S(\rho) = -\,\mathrm{Tr}(\rho \log \rho),$$

with a proof via simultaneous block-diagonalization, a discrete Fourier twirl that displays a random-unitary decomposition, Ky–Fan majorization, and Schur–concavity (Lemma 15.30, Proposition 15.31, and Definition 15.27).

Chronogeometric time and effective reduced evolution. In the macroscopic timelike regime the emergent proper time is

$$t_{\mathrm{geom}}(x,x') = \Big[\bar{g}_{\mu\nu}(x)\, \Delta x^\mu \Delta x^\nu\Big]^{1/2} \quad (\textit{Definition 5.95}),$$

and the reduced dynamics on $\mathcal{A}_A$ assumes the time-local GKLS form

$$\dot{\rho}_A(t) = -i\,[H_{A,\mathrm{eff}}(t), \rho_A(t)] \;+\; \text{interaction/monitoring terms from } \hat{H}_{AE},$$

with t the Good-clock axis aligned with $\bar{\Sigma}$ in the macroscopic regime (Definitions 5.95, 13.158 and 15.25). The unital CP–divisible Markovian limit is described next.

Stage 3: causal architecture and admissible reduced dynamics. Expectation–level chrono-geometry $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$ fixes the effective light–cone and Σ–causal support, ensuring monitoring/measurement on the record algebra cannot signal superluminally (see Definitions 5.26, 5.122 and 5.150 and Corollary 5.145). This supports a unital, CP–divisible continuum limit with channel-anisotropic rates when $\mathcal{U}_{\Phi\Theta}$ is anisotropic, formalised in Definition 15.37, Assumption 15.39, and Propositions 15.41 and 15.43. Admissible (CP–divisible) reduced dynamics $\{\Lambda_t\}_{t\geq 0}$ are defined precisely in Definition 15.37 (two-parameter family, composition law, divisibility).

Product–limit GKLS generator on the active band. With coarse-graining on the state-conditioned active band $\mathcal{H}_{\mathrm{act}}$ (Definition 15.56) and the finite-dimensionality postulate (Assumption 15.39), the Trotterized maps

$$\Lambda_t^{(n)} := \Big(\mathbb{E}_A \circ \mathrm{Ad}_{e^{-iH_{A,\mathrm{eff}}t/n}}\Big)^n$$

converge to a unital CPTP semigroup with GKLS generator $\mathcal{L}$ (Proposition 15.41). If $\mathcal{U}_{\Phi\Theta}$ is anisotropic, the resulting CP–divisible rates are channel-anisotropic while preserving Σ-causal support (cf. Definition 15.25 and Proposition 15.43).

Zeroth Law in the IQR setting (contextual highlight). Equilibrium equality $\mathrm{Eq}^{[\chi]}_{\mathrm{phys}}(\mathfrak{B}_A, \mathfrak{B}_B \mid \mathfrak{P})$ is obtained by projection to $\mathcal{H}_{\mathrm{phys}} = H^0(\hat{Q}_{\mathrm{BRST}})$, together with clock-gauge invariance and Σ-causal support (Theorem 15.7).

First Law (diagnostic realized reference configuration-wise). On a diagnostic realized reference configuration $\mathfrak{B}^{\langle \mathrm{DRRC}\rangle}$,

$$U_A(t) := \mathrm{Tr}\Big(\rho_A(t) H_A(t)\Big), \qquad \boxed{\Delta U_A = Q - W} \quad \text{(eq. (15.12))},$$

where Q is the incoherent contribution to ΔU_A generated by unital CP–divisible reductions $\mathbb{E}_A$, and W is the coherent Good-clock contribution from $H_A(t)$ (see Theorem 15.18, Definition 15.14, and Section 15.1.3).

> For an interacting subsystem A (coupled to an environment E with $\hat{H} = \hat{H}_A + \hat{H}_E + \hat{H}_{AE}$—environment Hamiltonian $\hat{H}_E$ plus interaction $\hat{H}_{AE}$ with A), *energy is relational*: along the Good-clock flow, the internal energy
>
> $$U_A(t) := \mathrm{Tr}\Big(\rho_A(t)\, H_A(t)\Big)$$
>
> changes only by heat current into A minus external power on A,
>
> $$\frac{dU_A}{dt} = J_A^{(Q)}(t) - P_A(t),$$

with expectations taken in the emergent inner product (from $\hat{G}_\Lambda$). These rates may be written equivalently as

$$J_A^{(Q)}(t) := \Big\langle i\,[\hat{H}_{AE}, \hat{H}_A] \Big\rangle = \mathrm{Tr}\Big(H_A\,\dot{\rho}_A(t)\Big),$$
$$P_A(t) := -\Big\langle \partial_t \hat{H}_A \Big\rangle = -\,\mathrm{Tr}\Big(\rho_A(t)\,\partial_t H_A(t)\Big).$$

When the interaction splits across the fundamental fields, $\hat{H}_{AE} = \hat{H}_{AE}^{(\mathbf{\Phi})} + \hat{H}_{AE}^{(\mathbf{\Theta})}$, the heat current decomposes componentwise in the Gaiamiti and Tantrakyma sectors:

$$J_A^{(Q)}(t) = \Big\langle i\,[\hat{H}_{AE}^{(\mathbf{\Phi})}, \hat{H}_A] \Big\rangle + \Big\langle i\,[\hat{H}_{AE}^{(\mathbf{\Theta})}, \hat{H}_A] \Big\rangle =: J_{A,\mathbf{\Phi}}^{(Q)}(t) + J_{A,\mathbf{\Theta}}^{(Q)}(t),$$

where $\hat{\mathbf{\Phi}}$ (Gaiamiti) and $\hat{\mathbf{\Theta}}$ (Tantrakyma) are the fundamental fields mediating exchanges. Consequently, over any interval $[t_0, t_1]$,

$$\Delta U_A = \int_{t_0}^{t_1} J_A^{(Q)}(t)\,dt \;-\; \int_{t_0}^{t_1} P_A(t)\,dt \;=\; Q_A - W_A.$$

Second Law (differential H–theorem). For admissible reduced dynamics one has

$$\frac{d}{dt} S_A(t) \;\geq\; 0,$$
with equality iff $[\rho_A(t), P_k] = 0\ \forall k$ and either $\kappa = 0$ or $\mathbb{E}_A(\rho_A(t)) = \rho_A(t)$,

so entropy is monotone and becomes flat precisely on the record algebra under purely unitary motion there (Theorem 15.50, eq. (15.14), and Corollary 15.48). Time and entropy co-emerge from Page–Wootters conditioning and einselection; Good-clock gauge-class invariance and macroscopic alignment with t_{geom} are explicit (Proposition 13.172, Definition 13.158, Lemma 15.6, and Theorem 13.168).

Second Law (relational form). Along any Good–clock axis t, the reduced state $\rho_A(t)$ follows a unital flow that is *divisible into intermediate completely positive, trace-preserving quantum channels* (CP-divisible), driven by the current–kernel coupling of the Fourfold correlator $\hat{G}_\Lambda$ and the pointer channel $\mathbb{E}_A$:

$$\dot{\rho}_A(t) \;=\; -\,i\,[H_{A,\mathrm{eff}}, \rho_A(t)] \;+\; \kappa\Big(\mathbb{E}_A(\rho_A(t)) - \rho_A(t)\Big),$$
$$\underbrace{\mathbb{E}_A(\rho) = \sum_k P_k\,\rho\,P_k\,.}_{\text{einselection}}$$

$$\underbrace{\forall\, t \geq r \geq s\ \exists\ V_{t,r}\ \text{CPTP}:\ \ \Phi_{t\leftarrow s} = V_{t,r}\circ\Phi_{r\leftarrow s},\quad \Phi_{t\leftarrow s}(\mathbb{I}_A) = \mathbb{I}_A}_{\text{CP-divisible, unital}}$$

$$\underbrace{P_j P_k = \delta_{jk} P_k, \qquad \sum_k P_k = \mathbb{I}_A,}_{\text{record projectors}}$$

$$\underbrace{\mathbb{E}_A^2 = \mathbb{E}_A}_{\text{pinching (conditional expectation)}},$$

$$\underbrace{\mathcal{R}_A = \{X \in \mathcal{B}(\mathcal{H}_A) : [X, P_k] = 0\ \forall k\} = \mathrm{Fix}(\mathbb{E}_A)}_{\text{record algebra and fixed points}}$$

With probabilities/expectations taken in the emergent inner product (from $\hat{G}_\Lambda$), the von Neumann entropy of A cannot decrease:

$$t_2 \geq t_1 \implies S_A(t_2) \geq S_A(t_1),$$
$$\frac{d}{dt} S_A(t) = \kappa\ \mathrm{Tr}[\rho_A(t)\log\rho_A(t) - \mathbb{E}_A(\rho_A(t))\log\rho_A(t)] \geq 0.$$

All increase is due to environment-induced superselection (the conditional expectation $\mathbb{E}_A$ onto $\mathcal{R}_A$); equality holds iff

$$[\rho_A(t), P_k] = 0\ \forall k \quad \text{and} \quad \mathbb{E}_A(\rho_A(t)) = \rho_A(t) \quad \text{or} \quad \kappa = 0,$$

i.e. the state already lies in the record algebra and the instantaneous motion on that commutant is unitary. Causality is respected: the flow preserves $\bar{\Sigma}$–lightcone support and admits no-law-signalling.

Third Law: coherence and residual entropy. For fixed $t < \infty$ on the active band $\mathcal{H}_{\text{act}}$,

$$\lim_{g\to 0} S\Big(\Lambda_t^{(g)}\rho_A(0)\Big) = S\Big(\rho_A(0)\Big), \qquad \lim_{g\to 0}\Lambda_t^{(g)} = \mathrm{Ad}_{e^{-iH_{A,\text{eff}}t}},$$

so the information-theoretic arrow flattens ($\dot{S} = 0$) (Proposition 15.52). If $H_{A,\text{eff}}$ has a $\mathfrak{g}$-fold degenerate ground space, then asymptotically on that manifold

$$S_0 = \log\mathfrak{g} \quad (k_B = 1),$$

and $S_0 = 0$ when $\mathfrak{g} = 1$ (Corollary 15.53). A two-level summary consolidates: (P) no thermodynamic map below the Planck floor; (R) vanishing production in isolation; residual $S_0 = \log\mathfrak{g}$; and strengthened unattainability at finite resources (Corollary 15.68).

Third Law (relational form — coherence and unattainability). On an *instrumented realization on a certified plateau* with a Good–clock $C = (\hat{T}, U_t)$ and

state–conditioned active band $\mathcal{H}_{\rm act}$, the reduced evolution at coupling $g\geq 0$ is the unital, CP–divisible flow $\{\Lambda_t^{(g)}\}_{t\geq 0}$ on $\mathcal{B}(\mathcal{H}_{\rm act})$ generated by

$$\mathcal{L}_g[\rho] = -\,i\,[H_{A,\rm eff},\rho] + \sum_\alpha \gamma_\alpha(g)\Big(L_\alpha \rho L_\alpha^\dagger - \tfrac{1}{2}\{L_\alpha^\dagger L_\alpha,\rho\}\Big)\,,$$
$$\Gamma(g) := \sum_\alpha \gamma_\alpha(g) \;\xrightarrow[g\downarrow 0]{}\; 0.$$

Coherence (isolation) limit. For every finite t,

$$\boxed{\lim_{g\to 0}\Lambda_t^{(g)} = \mathrm{Ad}_{e^{-iH_{A,\rm eff}t}}, \qquad \lim_{g\to 0} S\Big(\Lambda_t^{(g)}\rho\Big) = S(\rho), \qquad \lim_{g\to 0}\dot S_A^{(g)}(t) = 0}$$

i.e. entropy production *flattens* and the flow becomes unitary (asymptotic coherence).

Unattainability under finite resources. Any *instrumented realization on a certified plateau*–admissible, resource–bounded control with $\|H_{AE}(t)\| \leq g_{\max}$, $\Gamma(g(t)) \leq \kappa_{\max}$ and causal/Planckian onset

$$\underbrace{T_{\rm on} := \max\Big\{T_{\rm sig},\, \tau_{\rm Pl}^{(\rm thermo)}\Big\}}_{\substack{\text{signal latency / Planck floor}\\ (\Sigma\text{–causal \& timing constraints})}}$$

obeys, for any $T>0$ and any pure $|\psi\rangle$,

$$\boxed{\Big\|\rho_A(T) - |\psi\rangle\langle\psi|\,\Big\|_1 \geq \Big[\;\delta_0 - \underbrace{(c_1 g_{\max} + c_2\kappa_{\max})}_{\text{resource envelope}}\,(T - T_{\rm on})\;\Big]_+,}$$
$$\boxed{\delta_0 := \inf_{|\psi\rangle}\Big\|\rho_A(0) - |\psi\rangle\langle\psi|\,\Big\|_1 > 0}$$

(where $[x]_+ := \max\{x,0\}$). Equivalently,

$$T \;\geq\; T_{\rm on} + \frac{\delta_0 - \epsilon}{c_1 g_{\max} + c_2\kappa_{\max}} \quad \text{to reach} \quad \Big\|\rho_A(T) - |\psi\rangle\langle\psi|\,\Big\|_1 \leq \epsilon.$$

Residual entropy (degenerate ground spaces). Let P_0 project onto the ground manifold of $H_{A,\rm eff}$ and $\mathfrak{g} := \mathrm{rank}\,P_0$. If the long–time unital dynamics is ergodic on $P_0\mathcal{H}_{\rm act}$, then

$$\boxed{\lim_{g\to 0}\lim_{t\to\infty}\rho_A^{(g)}(t) \;=\; \frac{P_0}{\mathfrak{g}}, \qquad S_0 \;=\; \log\mathfrak{g}}$$

so $S_0 = 0$ iff the ground state is nondegenerate.

Causality and gauge. The flow preserves $\bar\Sigma$–lightcone support and is invariant in the Good–clock gauge class: no law–signalling, and all statements hold for any admissible emergent time variable.

Endogenous cutoffs, Planck floor, and active band. Thermodynamics applies only on the realized level; the pre-physical level is outside thermodynamic applicability (Definition 15.54). Any diagnostic realized reference configuration satisfies the Planck floor,

$$\Delta t \geq \tau_{\mathrm{Pl}}^{(\mathrm{thermo})} > 0, \qquad \Delta \ell \geq \ell_{\mathrm{Pl}}^{(\mathrm{thermo})} > 0 \quad (\textit{Definition } 15.55),$$

and the active band $\mathcal{H}_{\mathrm{act}}$ is fixed by state-conditioned spectral thresholds (Definition 15.56 and Assumption 15.39).

Resource-bounded control, Lipschitz bounds, and unattainability. Generator and trajectory norms obey

$$\|\mathcal{L}_{g(t)}\|_{1\to 1} \leq c_1 g_{\max} + c_2 \kappa_{\max},$$
$$\|\rho_A(t) - \rho_A(s)\|_1 \leq (c_1 g_{\max} + c_2 \kappa_{\max})\,|t-s| \quad (\textit{Lemma } 15.60),$$

and incorporating the Planck floor yields the earliest actionable time

$$t \;\geq\; T_{\mathrm{on}} := \max\{T_{\mathrm{sig}}, \tau_{\mathrm{Pl}}^{(\mathrm{thermo})}\} \quad (\textit{Lemma } 15.61).$$

For mixed $\rho_A(0)$ on $d := \dim \mathcal{H}_{\mathrm{act}} \geq 2$,

$$\inf_{\text{admissible controls on } [0,T]} \; \inf_{|\psi\rangle} \left\| \rho_A(T) - |\psi\rangle\langle\psi| \right\|_1 \;\geq\; \Big[\, \delta_0 - (c_1 g_{\max} + c_2 \kappa_{\max})\,(T - T_{\mathrm{on}}) \,\Big]_+,$$

so attaining a pure state in finite T requires resources that scale accordingly (Theorem 15.65 and Proposition 15.62). Within the two-level applicability and with resource-bounded control, no finite Good-clock time $T < \infty$ can reach the pre-physical PQS regime or an exactly PQS-coherent state; one needs $t_n \uparrow \infty$ with vanishing AE correlations (Corollary 15.63).

Synthesis of the laws. The First Law ($\Delta U_A = Q - W$) separates incoherent exchange (heat via $\mathbb{E}_A$) from coherent Good-clock driving (work) (eq. (15.12)). The Second Law ensures entropy production via pinching, with equality only on the record algebra under unitary motion there (Theorem 15.50 and eq. (15.14)). The Third Law states that at finite times the isolation limit preserves coherence and any residual entropy equals $\log \mathfrak{g}$ from ground-space degeneracy (Proposition 15.52 and Corollary 15.53). Altogether, these statements are Good-clock gauge-invariant and consistent with Σ-causal support, so the arrow of time emerges as information flow under unitary+einselection dynamics on the active band, unifying chronogeometry, entropy, and macroscopic evolution (Proposition 15.41 and Definitions 5.26 and 13.158).

Chapter 16: Black Hole Physics

Chapter 16 develops a black-hole physics of the relational programme by placing the information problem at center stage. After recalling Hawking's discovery that black holes radiate thermally [87], the chapter formulates the information paradox as a tension between semi-classical thermality and quantum unitarity, and frames its modern resolution in terms of entanglement entropy and the Page curve [138, 139]. In this account, the event horizon becomes the locus where classical description meets quantum coherence, and the paradox is

re-posed as a question about how correlations are transferred during evaporation (Section 16.1) [140, 20].

The technical core is a sourced, covariant wave equation for the temporal curvature tensor, $\Box_{\bar{g}}\bar{t}_{\mu\nu} + \mathcal{M}_{\mu\nu\rho\sigma}[\bar{g}]\bar{t}^{\rho\sigma} = \kappa'\langle\hat{T}^{\rm vac}_{\mu\nu}\rangle$ (eq. (16.467)), which encodes a dynamical feedback loop between Hawking flux and near-horizon chronogeometry. From this, the chapter defines a "temporal entropy density" $\sigma_t = \frac{1}{2}\bar{t}_{\mu\nu}\bar{t}^{\mu\nu}$ and establishes an information-conservation law $S_{\rm rad}(t) + S_t(t) = S_{\rm initial}$ governing unitary evaporation (Section 16.5) [20]. The early-time rise, turnover at t_P, and late-time decline of $S_{\rm rad}(t)$ (the Page curve) are then derived as the anti-phased exchange between stored temporal coherence and radiative entanglement, rendering "islands" and related holographic structures as effective summaries of the deeper relational dynamics [139, 140].

Finally, the horizon is reinterpreted as an ontological phase boundary between the macroscopic geometric regime and the mesoscopic relational regime (Section 16.1.10), with its radius determined by a transcendental relation corrected by vacuum coherence, $R_{\rm EH} + \alpha(\xi(R_{\rm EH})) = \frac{2GM}{c^2}$ (eq. (16.21)) [40, 42]. In the rotating case, the horizon acquires the quantum-corrected Kerr shift $R_{EH} \approx R^{(0)}_{EH} - \frac{a^2}{2R^{(0)}_{EH}}$ (eq. (16.426)), enabling a unified thermodynamics that maps the First/Second/Zeroth/Third Laws onto surface gravity, horizon area, and extremality bounds for the corrected geometry (Section 16.5) [141, 40]. The chapter closes by sketching observational handles—shadows, spectra, waveforms—and by making the unitary mechanism explicit: information stored in the central PQS is transferred to Hawking quanta via Apeiron/Kymon exchange across the shimmering horizon interface, resolving the paradox in a single relational narrative [122, 20].

In this relational account, the exterior "thermality" is explained algebraically rather than dynamically: restricting to the exterior algebra at (and outside) a Killing horizon yields a KMS state with respect to the horizon flow χ^a. Concretely,

$$\hat{K}_\omega = \beta_{\rm KMS}\hat{H}_\chi + c\,\mathbf{1} \quad ((16.481)),$$

and horizon regularity fixes $\beta_{\rm KMS} = 2\pi/\kappa$. Hence

$$T_H = \frac{\hbar\,\kappa_{\rm eff}}{2\pi k_B}, \qquad \kappa_{\rm eff} = \frac{c^2}{2}\,F'(R_{\rm EH}) \quad (eq.\ (16.5)),$$

so an exterior observer records KMS "thermality" while the global state remains pure (see Section 16.1.1). This resolves the apparent clash between semi-classical temperature and microscopic unitarity without altering quantum theory.

Geometrically, the unified lapse

$$N^2(r) = 1 - \frac{f(r)}{r} - A(r)$$

encodes the horizon as its largest root (eqs. (16.21) and (16.84)). Working perturbatively with $A(r) = \varepsilon\,a_1(r)$ and $f(r) = R_S + \varepsilon\,f_1(r)$, the first-order shift is

$$\delta R = f_1(R_S) - R_S\,a_1(R_S) \quad (eq.\ (16.161)),$$

so that $R_{\rm EH} = R_S + \varepsilon\,\delta R < R_S$ when $\rho_{\rm vac} > 0$. Equivalently,

$$\alpha\Big(\xi(R_{\rm EH})\Big) = R_S - R_{\rm EH} = -\,\varepsilon[f_1(R_S) - R_S a_1(R_S)] > 0 \quad (eq.\ (16.162)),$$

and this same horizon data fixes $\kappa_{\rm eff}$ via eq. (16.78) and T_H via eq. (16.79). The area/entropy shift then follows from $A_H = 4\pi R_{\rm EH}^2$,

$$S = \frac{A_H}{4G\hbar} = \frac{\pi R_S^2}{G\hbar}\Big(1 + 2\varepsilon\,\frac{\delta R}{R_S}\Big) + \mathcal{O}(\varepsilon^2),$$

providing a controlled $\mathcal{O}(\varepsilon)$ deviation tied to the same relational corrections.

Dynamically, the sourced evolution

$$\Box_{\bar g}\bar t_{\mu\nu} + \mathcal{M}_{\mu\nu\rho\sigma}[\bar g]\bar t^{\rho\sigma} = \kappa'\,\langle \hat T^{\rm vac}_{\mu\nu}\rangle \quad (eq.\ (16.467))$$

is complemented by a state-conditioned, band-limited source profile with spectral form

$$\rho_{\rm vac}(r) = \int_{\lambda_{\rm IR}(r)}^{\lambda_{\rm cutoff}(r)} \rho(\lambda;\bar\Sigma)\, w(\lambda;\,|\mathring{\mathbf{\Psi}}\rangle)\, E(\lambda;\bar\Sigma)\, d\lambda \quad (eqs.\ (16.129) and\ (16.130)),$$

so information is redistributed between the temporal sector and radiation rather than destroyed. This is captured by the conservation law

$$S_{\rm rad}(t) + S_t(t) = S_{\rm initial} \quad (Section\ 16.5),$$

whose early growth, turnover at t_P, and late decline reproduce the Page-curve morphology as an anti-phased exchange of correlations.

In the rotating setting, the dressed horizon/ergoregion are defined by the unified chrono-geometry: with $\chi^a = \partial_t + \Omega_H\,\partial_\phi$, the ergosurface satisfies $\bar\Sigma_{tt} = 0$ (eq. (16.202)) and the horizon is the largest root of $\bar\Sigma_{ab}\chi^a\chi^b = 0$ with

$$\Omega_H = -\frac{\bar\Sigma_{t\phi}}{\bar\Sigma_{\phi\phi}}\Big|_{r=R_H} \quad (eq.\ (16.203)).$$

To leading order one finds the quantum-corrected Kerr shift

$$R_{\rm EH} \approx R_{\rm EH}^{(0)} - \frac{a^2}{2\,R_{\rm EH}^{(0)}} \quad (eq.\ (16.426)),$$

and the associated unified thermodynamics is organized in Section 16.5, mapping the classical laws to surface gravity, corrected horizon area, and extremality bounds.

Finally, the framework ties directly to observations. Collecting the horizon-value data into

$$\boldsymbol{\theta} = \Big(a_1(R_S),\ f_1(R_S)/R_S,\ R_S a_1'(R_S),\ R_S f_1'(R_S)\Big),$$

one obtains leading QNM shifts,

$$\frac{\delta\omega_{\ell n}}{\omega_{\ell n}} = \mathcal{O}\Big(a_1(R_S),\ \tfrac{f_1(R_S)}{R_S},\ R_S a_1'(R_S),\ R_S f_1'(R_S)\Big),$$

and $\mathcal{O}(\varepsilon)$ deformations of the photon ring/shadow through the corrected lapse N^2. Together with the modular/KMS account of T_H (eq. (16.5)) and the conservation law above, this operationalizes the unitary mechanism: information stored in the central PQS is exported to Hawking quanta via Apeiron/Kymon exchange across the horizon interface, completing the single relational narrative introduced at the beginning of the chapter.

Opening motivation: horizons, singularities, and the information paradox. Chapter 16 motivates the program by treating the event horizon as a quantum–relational phase boundary and the putative singular interior as a limit of relational breakdown rather than a place [40, 42, 141, 20]. Within this framing, Hawking's prediction of an apparently thermal flux is put into tension with microscopic unitarity and the Page-curve expectation for entropy recovery [87, 138, 139]. The chapter's response is to embed black-hole physics in the IQR framework, where the exterior "thermality" arises from a modular/KMS restriction and coarse-graining, while the global state remains pure [30, 140]. The goal is a concrete, testable completion: derive horizon thermodynamics, locate and shift the event horizon relative to the classical Schwarzschild radius, and propagate those corrections into observables, all while keeping cross-references to the underlying field equations and modular structure explicit [40, 30].

The dual nature of Hawking radiation and the Hawking/KMS temperature. In the "isotropic" gauge $A = B$, the effective surface gravity simplifies to

$$\kappa_{\text{eff}} = \tfrac{c^2}{2}\, F'(R_{\text{EH}}),$$

which yields the Hawking temperature

$$T_H = \frac{\hbar\, \kappa_{\text{eff}}}{2\pi k_B} \xrightarrow[A=B=0]{\text{Schwarzschild}} \frac{\hbar c^3}{8\pi G M k_B},$$

as stated in (16.5). The chapter emphasizes the *dual* reading of Hawking radiation: it appears thermal to an exterior observer who restricts to a KMS algebra and coarse-grains over inaccessible modes, but the global state—treated in the IQR description—remains pure. This is elaborated in Section 16.1.1, where the KMS condition and environment-induced decoherence reconcile apparent thermality with unitary evolution.

Unified field equations for black holes. The dynamics are written in terms of the chrono-geometric tensor $\bar{\Sigma}_{\mu\nu}$, which combines the geometric and temporal sectors. Specializing the unified (semi-classical) Einstein equations to black-hole contexts leads to the vacuum constraints

$$\bar{G}_{\mu\nu}[\bar{\Sigma}] = 0,$$

to be solved subject to regularity at the horizon and asymptotic flatness at spatial infinity. This unified vacuum problem furnishes the stage on which horizon conditions, surface gravity, and thermodynamics are computed consistently from $\bar{\Sigma}_{\mu\nu}$.

Modeling the emergent geometry (static, spherically symmetric sector). In the static, spherically symmetric sector (Section 16.1.3), the chapter adopts a diagonal ansatz for $\bar{\Sigma}_{\mu\nu}$ encoded by the unified line element (16.18) together with the radial temporal tensor (16.108), featuring a lapse $N^2(r)$, a mass–length function $f(r)$ in the geometric block, and a temporal sector $\{A(r), B(r)\}$ [45, 43]. This ansatz converts the unified equations into coupled ordinary differential equations for $\{f; A, B\}$ (Sections 16.1.2 and 16.1.16) driven by dressed-vacuum sources, while the horizon and asymptotic conditions supply boundary data (cf. eq. (16.84)) [141]. The construction is designed so that horizon thermodynamic quantities can be read off directly from the lapse and its radial derivatives [40, 42].

The event horizon as a phase boundary. With the static ansatz, the lapse assumes the unified form

$$N^2(r) \;=\; 1 - \frac{f(r)}{r} - A(r).$$

The event horizon $R_{\rm EH}$ is defined as the largest root of this relation, equivalently the "phase boundary'' condition of eq. (16.84) together with the horizon conditions eqs. (16.16) and (16.21) [141]. These same relations anchor the effective surface gravity and temperature through eqs. (16.78) and (16.79); see the classical laws of black-hole mechanics and their thermodynamic identifications and Hawking's temperature [40, 87, 42].

Deriving the working equations (temporal tensor + geometric back-reaction). Projecting the unified equations onto the temporal sector yields an operator equation for the tt-profile A: a Lichnerowicz-type operator acting on A, sourced by the dressed vacuum (semiclassical back-reaction framework) [44, 43, 12, 40]. Simultaneously, the lapse is constrained by

$$N^2(r) \;=\; 1 - \frac{f(r)}{r} - A(r).$$

Combining these with the redshift/time-dilation relations in eq. (16.77), the phase-boundary condition in eq. (16.84), and the horizon relations in eqs. (16.16) and (16.21) yields the effective surface gravity eq. (16.78) and thereby T_H via eq. (16.79) [45, 141, 87, 40]. In the isotropic gauge $A = B$, the anisotropy vanishes and the first-order system closes cleanly (static, spherically symmetric reduction) [45]. Importantly, the apparent "halting of time'' at the horizon is interpreted as a projection/coarse-graining artifact; *chronogeometric viscosity* regularizes the flow that would otherwise become singular (for horizon-regular effective descriptions cf. the discussion of near-horizon thermodynamics) [40, 42].

Solving strategy I: asymptotic matching (outer solution). Outer solution ($r \gg R_S$)**.** In the decoupled, far-field regime, the operator equation for A reduces to a linear ODE whose Green's function exhibits a Yukawa-like kernel regulated by $\lambda \sim \ell_*$ (massive/regulated propagator in curved spacetime) [112, 12]. The geometric equation integrates to a mass–length profile governed by the sourced $\rho_{\rm vac}(r)$ [40]. Imposing asymptotic flatness fixes integration constants and yields outer data for $\{A, f\}$ that later serve as matching conditions for the near-horizon solution (standard asymptotic matching in semiclassical back-reaction) [141, 45, 112].

Horizon location and first-order shift By definition of the horizon,

$$N^2(r) = 1 - \frac{f(r)}{r} - A(r) = 0 \quad (\text{cf. } \textit{eqs.}\ (16.21) \textit{and}\ (16.78)).$$

Introducing a small parameter ε and writing

$$R_{\rm EH} = R_S + \varepsilon\, \delta R + \mathcal{O}(\varepsilon^2),$$

the chapter derives the model-independent relation

$$\delta R = f_1(R_S) - R_S\, a_1(R_S) \quad (\textit{eq.}\ (16.161)),$$

which implies $R_{\rm EH} < R_S$ when $\rho_{\rm vac} > 0$ (since $f_1(R_S) < 0$ and $a_1(R_S) \geq 0$). Equivalently, the "regime function"

$$\alpha\Big(\xi(R_{\rm EH})\Big) := R_S - R_{\rm EH} = -\,\varepsilon\,\delta R = -\,\varepsilon[f_1(R_S) - R_S a_1(R_S)] > 0 \quad (eq.\ (16.162))$$

quantifies the inward shift and propagates directly to $\kappa_{\rm eff}$ and T_H.

Thermodynamics at $\mathcal{O}(\varepsilon)$. With $A_H = 4\pi R_{\rm EH}^2$ and $R_{\rm EH} = R_S + \varepsilon\,\delta R$, the entropy shift is

$$S = \frac{A_H}{4G\hbar} = \frac{\pi R_S^2}{G\hbar}\Big(1 + 2\varepsilon\,\frac{\delta R}{R_S}\Big) + \mathcal{O}(\varepsilon^2).$$

Thus $\delta R < 0$ leads to a slight decrease relative to the classical area law, with consistent $\mathcal{O}(\varepsilon)$ shifts in $\kappa_{\rm eff}$ and T_H determined by eq. (16.79). These relations provide a direct bridge from the horizon shift to measurable thermodynamic corrections.

Predictions and phenomenology (ringdown & shadow). First-order corrections

$$A(r) = \varepsilon\, a_1(r), \qquad B(r) = \varepsilon\, b_1(r), \qquad f(r) = R_S + \varepsilon\, f_1(r)$$

imprint on near-horizon observables. For quasinormal modes (QNMs),

$$\frac{\delta\omega_{\ell n}}{\omega_{\ell n}} = \mathcal{O}\Big(a_1(R_S),\ \tfrac{f_1(R_S)}{R_S},\ R_S a_1'(R_S),\ R_S f_1'(R_S)\Big),$$

and the photon ring/black-hole shadow experiences $\mathcal{O}(\varepsilon)$ shifts through the corrected lapse N^2. The horizon-value parameter vector

$$\boldsymbol{\theta} = \Big(a_1(R_S),\ f_1(R_S)/R_S,\ R_S a_1'(R_S),\ R_S f_1'(R_S)\Big)$$

organizes the mapping from temporal/geometric profiles to constraints from spectroscopy and imaging.

Rotating extension: Chronogeometric Kerr program. (a) Relational affine structure. The unified tensor

$$\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu} \quad ((16.320))$$

defines the *Relational Levi–Civita derivative* with connection

$$\Gamma^{\lambda}{}_{\mu\nu}[\bar{\Sigma}] = \tfrac{1}{2}\,\bar{\Sigma}^{\lambda\rho}\Big(\partial_\mu\bar{\Sigma}_{\nu\rho} + \partial_\nu\bar{\Sigma}_{\mu\rho} - \partial_\rho\bar{\Sigma}_{\mu\nu}\Big),$$

and the split $\Gamma[\bar{\Sigma}] = \Gamma[\bar{g}] + \Delta\Gamma[\bar{t}]$ with first-order difference (16.323).

(b) Temporal sector ansatz. In Boyer–Lindquist form, the temporal tensor contributes

$$\bar{t}_{\mu\nu}\,dx^\mu dx^\nu = -A\,dt^2 + B\,\frac{\rho^2}{\Delta}\,dr^2 + C\,\rho^2\,d\theta^2 + E\,\sin^2\theta\,d\phi^2 - 2D\,\sin^2\theta\,dt\,d\phi,$$

as in (16.209).

(c) Rotationally dressed vacuum energy. The state-conditioned source is

$$\rho_{\rm vac}(x) := \left\langle \mathring{\mathbf{\Psi}} \right| \hat{\rho}^{(\rm eff)}(x) \left| \mathring{\mathbf{\Psi}} \right\rangle,$$

with $\hat{\rho}^{(\rm eff)} = \hat{\rho}^{(\rm static)} + \hat{\rho}^{(\rm rot)}$; the rotational contribution is a functional of $\hat{J}^{\mu\nu}$ and the chronogeometric vorticity $\hat{\omega}_{\mu\nu}[\bar{\Sigma}]$ built from the relational connection (Definition 16.5 and eq. (16.210)).

(d) Horizon & ergoregion in the unified geometry. With

$$\chi^a = \partial_t + \Omega_H \, \partial_\phi,$$

the ergosurface is defined by $\bar{\Sigma}_{tt} = 0$ ((16.202)); the horizon is the largest root of $\bar{\Sigma}_{ab}\chi^a\chi^b\big|_{r=R_H} = 0$ with

$$\Omega_H = -\frac{\bar{\Sigma}_{t\phi}}{\bar{\Sigma}_{\phi\phi}}\bigg|_{r=R_H} \qquad ((16.203)).$$

Small-spin/weak-dressing limits reduce to eq. (16.204) for (R_H, Ω_H).

(e) Kerr solution pipeline. The computation proceeds from **Relational Christoffels** in Section 16.5 through horizon/regularity and boundary conditions, culminating in the "Chronogeometric Kerr Solution," consistent with black-hole thermodynamics.

Modular/KMS identification on the horizon (zeroth law & temperature). Using Tomita–Takesaki modular theory, a $(\alpha_t, \beta_{\rm KMS})$–KMS state satisfies

$$\hat{K}_\omega = \beta_{\rm KMS}\hat{H}_\chi + c\,\mathbf{1} \quad ((16.481)),$$

so that near a Killing horizon one has $\beta_{\rm KMS} = 2\pi/\kappa$, hence

$$T_H = \frac{\kappa}{2\pi},$$

matching eq. (16.5). Step 4 identifies this with the horizon modular temperature

$$T_{\rm mod}(x) = \frac{\delta\langle \hat{H}_{\rm mod}(x)\rangle}{\delta S(x)} \quad (\textit{Proposition } 16.59),$$

providing the modular underpinning of the zeroth law in the unified setting.

Kerr horizons as observables: ergoregion, shifts, and constraints. To first order, horizon regularity enforces θ-independence of R_H and Ω_H in Kerr-like geometries (standard results for stationary, axisymmetric black holes) [142, 143, 141, 45]. The variations $(\delta R_H, \delta\Omega_H)$ are linear functionals of the temporal-sector data $\{A, B, D, E\}$ evaluated at the horizon, yielding a transparent pipeline from chronogeometric profiles to observable signatures: ringdown frequencies, late-time echoes, and black-hole shadow distortions [141]. This linear structure enables direct inference constraints on the temporal sector from spectroscopy and imaging [122].

Causal structure and CTCs reinterpreted as history transitions. Within IQR, extended Kerr closed timelike curves (CTCs) are reinterpreted as *branch transitions* mediated by a holosymmetric ring condensate. A classical CTC threading the ring corresponds to a nonzero off-diagonal amplitude $\hat{T}_{\beta\alpha}$, a partial isometry

$$\gamma_{\mathrm{CTC}} : \mathcal{H}_\alpha \to \mathcal{H}_\beta, \qquad \beta \neq \alpha,$$

implemented via the holosymmetric portal of Definition 16.23. Thus, "time travel" does not return one to their own past but bridges to a distinct history sector, consistent with the classical existence of CTC regions in Kerr and with general chronology considerations (formalized in eqs. (16.260) and (16.261)) [141, 20].

Dressed-vacuum sourcing (spectral, endogenous, state-conditioned). The effective source $\rho_{\mathrm{vac}}(r)$ entering the unified equations is state-conditioned and band-limited: a spectral integral that combines modal weights, an IR gap, and finite entanglement capacity into a localized, endogenous profile—mirroring semiclassical stress-tensor constructions in curved spacetime. This profile drives A, B and feeds back into f, closing the system at the level of $\bar{\Sigma}_{\mu\nu}$. The refined expressions and their spatial realizations are given in (16.129)–(16.130), ensuring that all near-horizon corrections remain tied to a physical (state-dependent) sourcing mechanism [12, 112].

Summary of testable predictions. The universal first-order conclusion is a slight inward displacement $R_{\mathrm{EH}} < R_S$ ($\delta R < 0$) with concomitant shifts in κ_{eff} and T_H (area/temperature relations and black-hole mechanics) [40]. These propagate into three principal families of observables: (i) ringdown spectroscopy, where

$$\frac{\delta\omega_{\ell n}}{\omega_{\ell n}} = \mathcal{O}\Big(a_1(R_S),\ \tfrac{f_1(R_S)}{R_S},\ R_S a_1'(R_S),\ R_S f_1'(R_S)\Big),$$

and multi-mode tests leverage LIGO/Virgo events [122]; (ii) black-hole shadow and photon-ring deformations controlled by the corrected lapse N^2, confronting imaging and accretion spectroscopy [141]; and (iii) area-law/temperature adjustments consistent with a *unitary* Page curve for a PQS-initialized microstate [138, 139, 42]. The parameter vector $\boldsymbol{\theta}$ at the horizon consolidates these effects into a compact, falsifiable response model that *directly* links the formalism's chronogeometric inputs to data.

Chapter 17: Cosmic Evolution

Chapter 17 develops the cosmic dynamics from a single relational action in which the curvature term and an invariant four-volume term yield Einstein–type field equations with an intrinsic vacuum stress–energy, thereby interpreting the cosmological constant Λ as the energy of the geometric vacuum (Section 17.1) [144, 145, 40, 146, 147]. Quantum-mechanically, Λ is fixed as the ground-state eigenvalue of the Geometric Hamiltonian, $\hat{H}_{\mathrm{geometry}}|\Psi_{\mathrm{vac}}\rangle = \Lambda|\Psi_{\mathrm{vac}}\rangle$ (Definition 17.2), and computed by a regulated spectral integral whose UV/IR bounds are physical, not ad hoc; a dynamical self-regulation between the geometric (*Gaiamiti*) and

material (*Tantrakyma*) sectors then drives a near-cancellation, leaving the small residual we observe as dark energy (Planck $\Omega_\Lambda \simeq 0.685$) (Sections 13.1 and 17.1.2) [112, 12, 148, 149, 150, 151, 152, 153, 154].

The chapter then elevates the *Universal Schrödinger Equation* $i\hbar\partial_t|\mathring{\mathbf{\Psi}}(t)\rangle = \hat{H}_{\rm rel}(t)|\mathring{\mathbf{\Psi}}(t)\rangle$ (eq. (17.47)) as the single dynamical law, with $\hat{H}_{\rm rel} = \hat{H}_{\rm geometry} + \hat{H}_{\rm matter}$ unifying dark energy/dark matter with the Standard Model sector. Crucially, $\hat{H}_{\rm rel}$ *emerges* from the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda(x, x')$: taking its local part, tracing, and integrating over the emergent manifold yields the global energy operator that drives cosmic evolution (Section 6.1.13) [22, 30, 49, 146, 155, 156, 47]. In this limit, familiar relations such as $E = mc^2$ are recovered as theorems of the relational architecture rather than imposed axioms (Section 17.1.6) [32, 20, 146].

Finally, the *Holocosmos Constraint* organizes two complementary cosmic regimes within a single timeless law: an *Ātmapoiesis* branch satisfying $\hat{H}_{\rm univ}|\mathring{\mathbf{\Psi}}\rangle = 0$ (self-contained, zero-total-energy universe), and a *Parapoiesis* branch driven by a transcendent source $\mathfrak{B}_{\vec{r}}$ with a fundamental arrow of time; an entangled holocosmic state cleanly decouples these into paired universal constraints (Sections 17.2.1 and 17.2.2). This synthesis is read as the highest articulation of the Law of Dependent Origination and the Axiom of Duality: the world's becoming and its being are two faces of one relational grammar (Section 17.2) [51, 156, 146, 157, 42, 17, 15, 35, 16].

1) The Law of Dependent Origination and Cosmic Evolution (Section 17.1). The chrono–geometric/IQR dynamics are fixed by a state-first, representation-independent principle together with diffeomorphism covariance, yielding the *Total Relational Action* (eq. (17.1)) [20, 42, 146]:

$$S_{\rm rel} = \frac{1}{2\kappa'}\int \big(\bar{R}[\bar{\Sigma}] - 2\Lambda\big)\sqrt{-\det\bar{\Sigma}}\, d^4x \;+\; S_{\rm matter}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}] \;+\; S_{\rm bdy}[\bar{\Sigma}],$$

where κ' is the relationally normalized coupling and Λ is the constant four-volume coefficient. Varying $S_{\rm rel}$ produces the Chronogeometric Einstein Equations with Λ (see eqs. (17.8) and (17.9)) and identifies the geometric (vacuum) stress as $T^{\rm vac}_{\mu\nu} = -(\Lambda/\kappa')\,\bar{\Sigma}_{\mu\nu}$ (eq. (17.10)) [146, 144, 145, 40]. Interferometric vacuum energy ε_Λ (defined through a holosymmetric projector on the vacuum sector) augments the bare constant to an *effective cosmological constant* $\Lambda_{\rm eff} = \Lambda + \kappa'\,\varepsilon_\Lambda$ (eq. (17.5)), with dark-energy density

$$\rho_{\rm DE} = \varepsilon_\Lambda = \frac{1}{{\rm Vol}(\mathcal{X}_q)}\Big\langle \mathring{\mathbf{\Psi}}\Big|\, \mathcal{P}^{\rm sym}_{\rm vac}\, H_{\rm vac}\, \mathcal{P}^{\rm sym}_{\rm vac}\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle_{\rm phys} \quad (eq.\ (17.4))$$

in the operator–algebraic/GNS setting [30, 22], consistent with regulated spectral constructions and EFT control [12, 112, 148, 149].

On the Hamiltonian side, the Legendre transform of $S_{\rm rel}$ together with the global relational balance yields the *Universal Quantum Constraint* $\hat{H}_{\rm univ}\,|\mathring{\mathbf{\Psi}}\rangle = 0$ (eqs. (13.236) and (17.6)), encoding the vanishing of total relational energy (geometry + matter/coherence) [156, 146, 51].

2) The Formal Origin of the Cosmological Constant (Section 17.1.2). Writing the geometric sector as

$$S_{\rm geom}[\bar{\Sigma}] = \frac{1}{2\kappa'}\int_{\mathcal{M}}\big(\bar{R}[\bar{\Sigma}] - 2\Lambda\big)\,{\rm d}\mu_{\bar{\Sigma}} \;+\; S_{\rm bdy}[\bar{\Sigma}], \qquad {\rm d}\mu_{\bar{\Sigma}} = \sqrt{-\det\bar{\Sigma}}\,{\rm d}^4x \quad (eq.\ (17.7)),$$

its variation gives

$$\delta S_{\text{geom}} = \frac{1}{2\kappa'}\int \sqrt{-\det \bar{\Sigma}}\,\left(\bar{G}_{\mu\nu} + \Lambda\,\bar{\Sigma}_{\mu\nu}\right)\delta\bar{\Sigma}^{\mu\nu}\,\mathrm{d}^4x \;+\; \delta S_{\text{bdy}} \quad (eq.\ (17.8)),$$

and, including matter, the Chronogeometric Einstein Equations

$$\bar{R}_{\mu\nu} - \tfrac{1}{2}\,\bar{\Sigma}_{\mu\nu}\,\bar{R} + \Lambda\,\bar{\Sigma}_{\mu\nu} = \kappa'\,T^{\text{matter}}_{\mu\nu} \quad (eq.\ (17.9)).$$

Because $T^{\text{vac}}_{\mu\nu} \propto \bar{\Sigma}_{\mu\nu}$ is geometrically *homogeneous* (eq. (17.10)), it drops out of null-directed energy conditions and is coherently placed on the geometric side of the response kernel [146, 144, 145, 40, 43].

3) The Quantum–Mechanical Nature of Λ and Self-Regulation (Section 17.1.2). At the operator level the geometric Hamiltonian admits a density-normalized vacuum,

$$\hat{H}_{\text{geometry}}\,|\Psi_{\text{vac}}\rangle = \Lambda_{\text{geo}}\,|\Psi_{\text{vac}}\rangle\,, \qquad \Lambda_{\text{geo}} = \frac{\langle\Psi_{\text{vac}}|\hat{H}_{\text{geometry}}|\Psi_{\text{vac}}\rangle_{\text{phys}}}{\text{Vol}(\mathcal{X}_q)} \quad (eq.\ (17.11)),$$

and endogenous (state-conditioned) regularization—via modal weights w_n, the *Principle of Finite Entanglement Capacity*, and a state-emergent cutoff—renders the spectrum finite (see Section 17.1.2) [12, 112, 148, 20, 147, 47, 49].

4) Physical Manifestation as Dark Energy and the Foundational Definition (Section 17.1.2). On cosmological scales,

$$\Lambda_{\text{eff}} = \Lambda + \kappa'\,\varepsilon_\Lambda, \qquad \rho_{\text{DE}} = \Lambda_{\text{eff}}/\kappa' \quad (eq.\ (17.12)),$$

implying an effective geometric vacuum stress $T^{\text{vac,eff}}_{\mu\nu} = -(\Lambda_{\text{eff}}/\kappa')\,\bar{\Sigma}_{\mu\nu}$ (cf. eq. (17.10)). The *Foundational Definition* (Definition 17.2) unifies: (i) Λ from the variational action, (ii) Λ_{geo} from $\hat{H}_{\text{geometry}}$, and (iii) Λ_{eff} as the phenomenological driver of late-time acceleration.

5) Calculating Λ: Regulated Spectral Integral (Section 17.1.2). In local trace form,

$$\hat{H}_{\text{geometry}} = \int_{\mathcal{X}_q} d^dx\,\sqrt{-\det\bar{\Sigma}(x)}\;\text{Tr}\big[\hat{G}_{\mathbf{\Phi\Phi}}(x,x)\big] \quad (eq.\ (17.13)),$$

leading (quasi-homogeneously) to

$$\Lambda_{\text{geo}} \propto \frac{1}{\text{Vol}(\mathcal{X}_q)}\left\langle \overset{\circ}{\mathbf{\Psi}}\middle|\hat{H}_{\text{geometry}}\middle|\overset{\circ}{\mathbf{\Psi}}\right\rangle_{\text{phys}} \simeq \int_{k_{\text{IR}}}^{k_{\text{UV}}}\frac{d^3k}{(2\pi)^3}\,E(k), \quad E(k) = \tfrac{1}{2}\hbar\,\omega_k + \cdots \quad (eq.\ (17.14)).$$

Self-regulation then leaves a *small positive residual*

$$\rho_{\text{DE}} = \varepsilon_\Lambda = \frac{1}{\text{Vol}(\mathcal{X}_q)}\left|\langle\hat{H}_{\text{geometry}}\rangle_{\text{phys}} + \langle\hat{H}_{\text{vac}}\rangle_{\text{phys}}\right| \ll \frac{k^4_{\text{UV}}}{16\pi^2}\hbar c \quad (eq.\ (17.15)).$$

6) Deriving Λ_{eff} in the Field Equations (Section 17.1.3). Starting from

$$S_{\text{geom}}[\bar{\Sigma}] = \frac{1}{2\kappa'}\int \big(\bar{R}[\bar{\Sigma}] - 2\Lambda\big)\sqrt{-\det \bar{\Sigma}}\, d^4x \quad (eq.\ (17.17)),$$

the bare-Λ equations read

$$\bar{R}_{\mu\nu} - \tfrac{1}{2}\,\bar{\Sigma}_{\mu\nu}\,\bar{R} + \Lambda\,\bar{\Sigma}_{\mu\nu} = \kappa'\,\bar{T}^{\text{matter}}_{\mu\nu} \quad (eq.\ (17.18)).$$

Splitting $\bar{T}^{\text{matter}}_{\mu\nu} = \bar{T}^{(\text{nonvac})}_{\mu\nu} + \bar{T}^{(\text{vac})}_{\mu\nu}$ with $\bar{T}^{(\text{vac})}_{\mu\nu} = -\varepsilon_\Lambda\,\bar{\Sigma}_{\mu\nu}$ (eqs. (17.19) and (17.20)) yields

$$\bar{R}_{\mu\nu} - \tfrac{1}{2}\,\bar{\Sigma}_{\mu\nu}\,\bar{R} + \underbrace{\big(\Lambda + \kappa'\varepsilon_\Lambda\big)}_{:=\Lambda_{\text{eff}}}\bar{\Sigma}_{\mu\nu} = \kappa'\,\bar{T}^{(\text{nonvac})}_{\mu\nu} \quad (eq.\ (17.21)),$$

i.e. the vacuum residue is coherently moved to the geometric side.

7) Measured Value and Bridge to IQR. Observations (Planck 2018 + external data) give $\Omega_\Lambda \simeq 0.685$ (eq. (17.42)) and $\rho^E_{\text{crit}} = 3c^2H_0^2/(8\pi G)$ (eq. (17.43)), hence

$$\rho_{\text{vac}} = \Omega_\Lambda\,\rho^E_{\text{crit}} \approx (5.3 \pm 0.3)\times 10^{-10}\ \text{J m}^{-3} \quad (eq.\ (17.44)),$$

and

$$\Lambda_{\text{eff}} = \frac{8\pi G}{c^4}\rho_{\text{vac}} \approx (1.1 \pm 0.1)\times 10^{-52}\ \text{m}^{-2} = \frac{3\,\Omega_\Lambda H_0^2}{c^2} \quad (eq.\ (17.45)).$$

In the present notation this is precisely $\Lambda_{\text{eff}} = \Lambda + \kappa'\,\varepsilon_\Lambda$ (eq. (17.46)).

8) The Universal Schrödinger Equation and $E = mc^2$ (Sections 17.1.5 and 17.1.6). Cosmic evolution in the physical sector is governed by

$$\boxed{i\hbar\frac{d}{dt}|\mathring{\mathbf{\Psi}}(t)\rangle = \hat{H}_{\text{rel}}(t)\,|\mathring{\mathbf{\Psi}}(t)\rangle} \quad (eq.\ (17.47))[22,\ 30].$$

with decomposition

$$\hat{H}_{\text{rel}} = \underbrace{\hat{H}_{\text{geometry}}[\hat{\Sigma}_{\mu\nu}]}_{\text{Dark Energy \& Dark Matter}} + \underbrace{\hat{H}_{\text{matter}}[\hat{\phi},\hat{\psi},\ldots]}_{\text{Standard Model}} \quad (eq.\ (17.48))[20,\ 42].$$

Within this framework, mass–energy equivalence $E = mc^2$ emerges through the chronogeometric couplings that identify inertial and energetic content (see Section 17.1.6) [32, 146].

9) The Law of Dependent Origination and Conservation of Duality (Section 17.1.7). At the deepest level the dynamics reduce to the timeless balance

$$\hat{H}_{\text{univ}}|\mathring{\mathbf{\Psi}}\rangle = 0 \quad (Section\ 17.1.7),$$

a background-independent statement of total relational conservation (geometry + sources), with "time" emerging relationally [156, 51, 146, 20].

10) The Unfolding/Enfolding and the Ātmapoiesis Universe (Sections 17.2 and 17.2.1). The macro-narrative of cosmic *unfolding* (phenomenal becoming) and *enfolding* (ontic coherence) is formalized as

$$\boxed{\hat{H}_{\text{univ}}|\overset{\circ}{\boldsymbol{\Psi}}\rangle = 0} \quad (eq.\ (17.49)),$$

expressing the self-consistency of the whole as the source of the parts in the Ātmapoiesis Universe [156, 51, 146, 42, 17, 15, 35, 16].

11) The Holocosmos: Entangled Dual Branches and Constraint Expansion (Section 17.3.1 and eqs. (17.59) and (17.60)). The holocosmos Hilbert space factorizes as $\mathcal{H}_{\text{holocosmos}} = \mathcal{H}_{\text{univ}} \otimes \mathcal{H}_{\mathfrak{B}}$, and the timeless entangled state

$$|\boldsymbol{\Omega}\rangle = \alpha\,|\overset{\circ}{\boldsymbol{\Psi}}_{\bar{\text{A}}\text{tmapoiesis}}\rangle \otimes |\bar{\text{A}}\text{tmapoiesis}\rangle + \beta\,|\overset{\circ}{\boldsymbol{\Psi}}_{\text{Parapoiesis}}\rangle \otimes |\text{Parapoiesis}\rangle \quad (eq.\ (17.61)),$$

obeys $|\alpha|^2 + |\beta|^2 = 1$ (eq. (17.62)). Coherence is enforced by the compact *holocosmos constraint*

$$\left(\hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}} - \mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}}\right)|\boldsymbol{\Omega}\rangle = 0 \quad (eq.\ (17.63)),$$

whose explicit expansion (eq. (17.59)) decouples to

$$\hat{H}_{\text{univ}}|\overset{\circ}{\boldsymbol{\Psi}}_{\bar{\text{A}}\text{tmapoiesis}}\rangle = 0, \qquad \hat{H}_{\text{univ}}|\overset{\circ}{\boldsymbol{\Psi}}_{\text{Parapoiesis}}\rangle = \mathfrak{B}_{\vec{r}}|\overset{\circ}{\boldsymbol{\Psi}}_{\text{Parapoiesis}}\rangle \quad (eq.\ (17.60)),$$

exhibiting a stationary branch and a sourced branch with c-number $\mathfrak{B}_{\vec{r}}$. The *Axiom of Holocosmic Duality* (Section 17.3.1) assigns ontological Born weights

$$|\alpha|^2 = v(\rho_\Omega; \Pi_A), \qquad |\beta|^2 = v(\rho_\Omega; \Pi_P), \quad |\alpha|^2 + |\beta|^2 = 1 \quad (eqs.\ (17.73) and\ (17.74)),$$

ensuring conservation of total ontic content.

12) The Law of Dependent Origination of the Holocosmos: Action Forms and Equivalences (Section 17.3.2). Let $A := \hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}} - \mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}}$. Physical holocosmic states lie in the kernel $A\,|\boldsymbol{\Omega}\rangle = 0$ (eq. (17.67)). Three equivalent variational forms enforce this: (1) Rayleigh–Ritz with norm constraint,

$$\overset{\circ}{\boldsymbol{\Lambda}}[\,\boldsymbol{\Omega}\,] = \langle\boldsymbol{\Omega}|A|\boldsymbol{\Omega}\rangle - \lambda\Big(\langle\boldsymbol{\Omega}|\boldsymbol{\Omega}\rangle - 1\Big) \;\Rightarrow\; A|\boldsymbol{\Omega}\rangle = \lambda|\boldsymbol{\Omega}\rangle,\ \lambda = 0 \quad (eqs.\ (17.68) and\ (17.69));$$

(2) the penalty functional $\boldsymbol{\Lambda}_{\text{pen}}[\,\boldsymbol{\Omega}\,] = \langle\boldsymbol{\Omega}|A^2|\boldsymbol{\Omega}\rangle - \lambda(\langle\boldsymbol{\Omega}|\boldsymbol{\Omega}\rangle - 1)$, whose minimum selects $\ker A$; and (3) the operator (vector–multiplier) constraint

$$\boldsymbol{\Lambda}_{\text{op}}[\,\boldsymbol{\Omega}, \chi\,] = \tfrac{1}{2}\Big(\langle\chi|A|\boldsymbol{\Omega}\rangle + \langle\boldsymbol{\Omega}|A|\chi\rangle\Big) - \lambda(\langle\boldsymbol{\Omega}|\boldsymbol{\Omega}\rangle - 1),$$

whose stationarity likewise enforces $A|\boldsymbol{\Omega}\rangle = 0$ (eq. (17.72)). The *Equivalence Proposition* (Proposition 17.24) proves that—under self-adjointness and $\ker A \neq \{0\}$—all three yield the same normalized physical solution set.

13) Concluding Synthesis (Section 17.3.4). Chapter 17 welds the *formal* (Λ from action), *quantum* (Λ_{geo} from $\hat{H}_{\text{geometry}}$), and *phenomenological* (Λ_{eff}) layers into one relational cosmology: evolution is governed by the Schrödinger form (eq. (17.47)) or, more fundamentally, by the timeless constraint (Section 17.1.7) [22, 30, 156, 51, 146, 20]. The holocosmos construction (eqs. (17.61) and (17.63)) encodes dual branches with ontological weights (eq. (17.73)) [158, 42], while the regulated spectral machinery (eqs. (17.13) and (17.14)) and coherent placement of vacuum stress (cf. eq. (17.21)) deliver a finite, positive ρ_{DE} (eq. (17.15)) consistent with observation (eqs. (17.42) and (17.45)) [112, 12, 148, 145, 144, 149, 150, 151, 152, 153, 154].

Prologue: Entanglement at the Foundations of Physics

The Inner Tangle and the Outer Tangle of Physics

From Clockwork Certainty to Quantum Hurricane At the close of the 19th century, the edifice of physics seemed nearly complete, resting upon the bedrock of Sir Isaac Newton's classical mechanics [159]. For over two centuries, Newton's laws had provided a deterministic, "clockwork" universe where reality was objective and particles followed predictable trajectories. This confidence was famously captured by Lord Kelvin in 1900 when he declared the beauty of the classical framework, noting only two minor "clouds on the horizon" that needed resolving [160]. These "clouds," however, were not minor atmospheric disturbances but the harbingers of a hurricane that would fundamentally reshape our understanding of reality. They pointed toward puzzling phenomena that classical physics could not explain, cracking the foundations of its deterministic certainty and ushering in the strange and subversive realm of quantum mechanics [161].

The Tremors in the Classical World The first true tremor came not from a new experiment but from a theoretical insight into one of Kelvin's clouds: the problem of *black-body radiation*. To explain the observed spectrum of light emitted by a hot object, German physicist *Max Planck* reluctantly proposed in 1900 that energy was not continuous but was emitted and absorbed in discrete packets, or "quanta" [162]. He saw this as a mathematical trick, yet he had opened Pandora's box. A few years later, *Albert Einstein*, then a young patent clerk, took Planck's idea seriously. To explain the *photoelectric effect*—a phenomenon discovered by Heinrich Hertz [163], where light could knock electrons off a metal surface—Einstein proposed in his "miraculous year" of 1905 that light itself is composed of these discrete particles, which he called "light quanta" and we now call *photons* [164]. This radical idea, for which he would later win the Nobel Prize, showed that light, long understood as a wave, also behaved as a particle.

This notion of *wave-particle duality* was the heart of the emerging quantum crisis. The most profound and unsettling demonstration of this duality came from reconsidering an old experiment with new entities. In the early 1800s, *Thomas Young* had conclusively shown that light was a wave by passing it through two narrow slits and observing an *interference pattern*—a characteristic pattern of alternating bright and dark fringes that could only be produced by waves interfering with each other [165]. A century later, inspired by the bold 1924 hypothesis from French physicist *Louis de Broglie* that all matter exhibits wave-like

properties [166], physicists performed the double-slit experiment with particles: *electrons*.

The results were paradigm-shattering. When a beam of electrons was fired at a barrier with two open slits, they did not simply create two bands on the detector screen as tiny pellets would. Instead, they produced the exact same interference pattern that Young had seen with light waves (demonstrated experimentally by *Davisson and Germer* in 1927 [167]). This forced a conclusion that defied all classical intuition: each individual electron, a supposed particle, seemed to pass through *both* slits simultaneously like a wave and interfere with itself. Even more bizarrely, if a detector was placed at the slits to see which path the electron took, the interference pattern vanished, and the electrons behaved like normal particles again. The very act of observing the particle's path forced it to "choose" a state, dissolving its wave-like nature. This experiment exposed the core quantum mystery: reality at the subatomic level is inherently probabilistic, and the observer is inextricably linked with the observed [168, 169].

The Copenhagen Interpretation: Probability, Collapse, and Complementarity The baffling results of the double-slit experiment demanded a new logic for reality, a logic codified in the late 1920s into what became the orthodox *Copenhagen interpretation*, primarily championed by *Niels Bohr* and *Werner Heisenberg* [168, 169]. According to this view, an electron is not a simple particle but is described by a *wave function*: a mathematical entity that represents a superposition of all its possible states. This wave, however, is not a physical substance but a wave of *probability*. This crucial insight came from *Max Born* in 1926, who proposed that the square of the wave function's amplitude at any given point corresponds to the probability of finding the particle there upon measurement [21].

Thus, when an unobserved electron travels toward the slits, its wave function passes through both, allowing it to interfere with itself. The interference pattern vanishes upon observation because of what the Copenhagen school called the *"collapse of the wave function."* The moment an interaction occurs that can yield information about the electron's path—for instance, a photon bouncing off it—the superposition of possibilities is destroyed. The spread-out wave of potential locations instantly "collapses" into a single, definite state at a specific point. As *Heisenberg* formalized in his famous 1927 uncertainty principle paper, the act of measuring one property (like position) inevitably disturbs another (like momentum), making it impossible to know both with perfect accuracy [54]. This isn't a limitation of our instruments; it's a fundamental feature of nature.

The Observer and the Observed It's crucial to understand that the "observer" in quantum mechanics need not be a conscious mind. Rather, it is any physical interaction with the environment that "records" the state of the system, a process now understood through the lens of *quantum decoherence* [170]. This interaction irrevocably entangles the particle with the measuring device, destroying the delicate superposition required for wave-like interference.

This insight strikes at the very heart of classical reality. It suggests that properties like an electron's position do not exist in a definite state until they are measured. This idea was expressed most clearly in *Niels Bohr's principle of complementarity*. Bohr argued that wave-like and particle-like behavior are mutually exclusive, or complementary, aspects of a single underlying reality. An experimental setup designed to reveal the particle's path will necessarily destroy the conditions needed to observe its wave-like interference, and

vice-versa [168]. We can never see both faces of the quantum coin at the same time. This led *Heisenberg* to his profound philosophical conclusion, articulated in *Physics and Philosophy*: "What we observe is not nature itself, but nature exposed to our method of questioning" [169]. The world "out there" is not a static stage to be passively viewed; it is a participatory reality where the act of measurement helps co-create the very properties being measured.

Indeterminacy and the Limits of Knowledge The philosophical upheaval ignited by quantum mechanics is powerfully encapsulated in *Werner Heisenberg's 1927 uncertainty principle* [54]. More than a statement about measurement limitations, the principle reveals a fundamental "fuzziness" inherent in nature. It states that certain pairs of properties, known as conjugate variables (like a particle's position and its momentum), cannot be simultaneously known to arbitrary precision. The more precisely one property is determined, the more uncertain the other becomes, governed by the famous inequality $\Delta x \Delta p \geq \hbar/2$. This is not because our instruments are clumsy; it is a law of nature. An electron, prior to measurement, simply *does not possess* a definite position and a definite momentum at the same time. Reality at this scale is partly indeterminate, a haze of potentialities waiting for an observation to force it into a concrete state.

Schrödinger's Cat Paradox The bizarre implications of this quantum indeterminacy being applied to the macroscopic world were famously dramatized by *Erwin Schrödinger* in 1935. Deeply troubled by the Copenhagen interpretation's concept of superposition, Schrödinger devised a thought experiment intended as a *reductio ad absurdum*—a critique to expose the theory's apparent absurdity. In his paper *"The Present Situation in Quantum Mechanics"*, he imagined a cat sealed in a box along with a vial of poison, a hammer, a Geiger counter, and a single radioactive atom [171, 172, 173].

If the atom decays (a fundamentally random quantum event), the Geiger counter will trigger the hammer, which will shatter the vial and kill the cat.

According to the quantum formalism, as long as the box remains sealed, the atom is in a superposition of two states: "decayed" and "not decayed." By extension, the entire system linked to it must also be in a superposition. The cat, therefore, is described by a wave function that represents it as being simultaneously *alive and dead*. This macabre state persists until a measurement is made—that is, until an observer opens the box. At that moment, the wave function "collapses", and a single, definite reality is revealed: either a living cat or a dead one. Schrödinger's paradox was not designed to suggest cats could actually be both alive and dead; it was designed to highlight the unresolved *measurement problem* [174, 175]. At what precise moment does the "fuzzy" quantum superposition collapse into the single, concrete reality we experience? Does it happen when the atom decays, when the Geiger counter clicks, or only when a conscious being intervenes? The paradox masterfully illustrates the conceptual chasm between the quantum world of potentialities and the classical world of definite facts, a chasm that remains a subject of intense debate to this day.

The Bohr-Einstein Debates: A Clash Over the Nature of Reality The foundational weirdness of quantum mechanics was so profound that it led to one of the greatest intellectual duels of the 20th century: a decades-long debate between Albert Einstein and Niels Bohr

over the very soul of physics. This was not a disagreement over equations but a clash of fundamental philosophies about what reality is and what science ought to describe.

Einstein's Realist Dissent Albert Einstein, whose work on the photoelectric effect was a crucial catalyst for the quantum revolution, became its most formidable critic. He could not accept a reality governed by what he saw as the incomplete and probabilistic nature of the new mechanics. His profound discomfort is immortalized in his 1926 letter to Max Born, where he famously declared, *"I, at any rate, am convinced that He [God] does not play dice"* [176]. For Einstein, a *realist*, the universe must possess definite, objective properties whether we are observing them or not. He famously challenged physicist Abraham Pais, "Do you really believe the moon exists only when you look at it?" mocking the idea that observation creates reality [177].

Einstein's core argument was not that quantum mechanics was wrong, but that it was *incomplete*. He believed that the theory's probabilistic nature was merely a reflection of our ignorance of a deeper, deterministic level of reality governed by as-yet-unknown "hidden variables." His most powerful challenge came in the form of the *1935 EPR paradox*, a thought experiment co-authored with Boris Podolsky and Nathan Rosen. The paper argued that quantum mechanics' description of entangled particles—which remain mysteriously connected over vast distances—implied a "spooky action at a distance" that, to Einstein, proved the theory must be missing something fundamental about the nature of local reality [178].

Bohr's Copenhagen Orthodoxy In the opposing corner stood *Niels Bohr*, the intellectual architect of the dominant *Copenhagen interpretation*. Bohr met Einstein's challenge with a radical philosophical shift, insisting that we must abandon our classical intuitions. For Bohr, the "spooky" features of quantum mechanics were not a sign of incompleteness but a revelation about the nature of knowledge itself. He argued that properties like position or momentum have no meaning independent of an experimental context designed to measure them [168, 179].

Bohr's response to Einstein was to double down on his *principle of complementarity*. An experimental setup defines what can be known. Any attempt to describe a quantum system's reality outside of this observational context was, in Bohr's view, meaningless language [180]. He famously articulated this stance by stating, *"There is no quantum world. There is only an abstract quantum physical description. It is wrong to think that the task of physics is to find out how nature is. Physics concerns what we can say about nature"* (as quoted by Petersen [181]). This startling claim redefines the goal of science: it is not to uncover a pre-existing, objective reality, but to build a consistent framework for what we can measure and communicate about our interactions with the world [182]. For Bohr, Einstein's question about what the particles were 'really" doing was a violation of the rules of the new quantum game.

The EPR Paradox: Einstein's Last Stand for Local Reality The simmering debate between Einstein and Bohr reached its theoretical zenith in 1935 with the publication of the *Einstein-Podolsky-Rosen (EPR) paradox* [178, 182]. This was Einstein's most sophisticated attempt to prove that quantum mechanics, while correct in its predictions, must be an *incomplete*

description of reality. The authors imagined two particles created from a single source, flying apart in opposite directions. By the laws of quantum mechanics, these particles could be *"entangled"*, meaning their properties remained linked in an inseparable wave function, no matter how far apart they traveled [171, 172, 173].

The EPR argument was brilliant: by measuring the momentum of particle A, one could instantly know the momentum of particle B without ever touching it. Alternatively, by measuring the position of particle A, one could know the position of particle B. According to their *"criterion of reality"*, if a property can be known without disturbing a system, it must correspond to a real element of that system. Therefore, particle B must have had both a definite position and a definite momentum all along. Since the uncertainty principle forbids a quantum state from having both, EPR concluded that the quantum description was missing information. This implied the existence of *"hidden variables"*—local properties of the particles that predetermined the measurement outcomes [183]. To Einstein, the alternative—that a measurement on particle A instantaneously affected particle B—was an absurdity he derisively called *"spooky action at a distance"* (*spukhafte Fernwirkung*), as it seemed to violate the cosmic speed limit set by light [184].

From Paradox to Proof: Bell's Theorem and Aspect's Experiments For nearly three decades, the EPR paradox remained a philosophical puzzle. The deadlock was finally broken in 1964 by the Irish physicist *John Stewart Bell*. In a groundbreaking paper, Bell demonstrated that if Einstein's hidden variables existed and obeyed the principle of locality, then the correlations between measurements on entangled particles could not exceed a certain mathematical limit. However, the standard predictions of quantum mechanics *did* exceed this limit. *Bell's theorem* thus transformed a philosophical debate into a physically testable question: the universe could be locally real (as Einstein hoped), or it could obey the predictions of quantum mechanics, but not both [183].

The definitive experiments were carried out in the early 1980s by a team led by French physicist *Alain Aspect*. By generating and measuring thousands of entangled photons, Aspect and his colleagues showed a clear and robust violation of Bell's inequality, with results that matched the predictions of quantum mechanics perfectly [184]. These experiments, since replicated with ever-increasing precision, effectively ruled out Einstein's worldview. Nature, at its deepest level, is either non-local (permitting a form of instantaneous connection) or non-realist (meaning particles do not have definite properties before measurement), or both. Einstein's cherished principle of *local realism* was not a feature of our universe.

The Enduring Quantum Conundrum TThe experimental vindication of quantum mechanics leaves us in a universe profoundly at odds with our intuition. The core tenets of this 'quantum crisis" can be summarized plainly. Firstly, *wave-particle duality* is a fundamental feature of reality; a quantum object is neither a wave nor a particle but a new kind of entity that reveals one aspect or the other depending on the experimental question asked [167, 168, 169]. Secondly, nature is irreducibly *probabilistic*. Einstein's insistence that 'God does not play dice" has been answered by experiment [176, 177]: chance is woven into the fabric of the cosmos. The outcome of a single quantum event cannot be predicted with certainty, only its probability [21, 54]. This is not a failure of our knowledge, but a fundamental principle of the

universe itself, representing a radical and permanent break from the deterministic clockwork of classical physics [169, 185].

Measurement as Creation The quantum revolution fundamentally redefined the act of measurement itself. In classical physics, to measure something is to passively reveal a pre-existing property. In quantum mechanics, measurement is an active process of creation. This radical idea was forcefully articulated by *Pascual Jordan*, a key collaborator in the development of matrix mechanics, who stated: *"Observations not only disturb what is to be measured, they produce it... We compel [an] electron to assume a definite position... We ourselves produce the results of measurement"* (as quoted in Jammer [186]). This is the staggering conclusion of the Copenhagen interpretation: an unobserved electron does not *have* a definite position; it exists in a haze of potentialities described by its wave function. The act of measurement forces this potentiality into a single actuality, creating the very property it seeks to find.

Entanglement and the End of Separability Nowhere is the break from classical intuition more severe than with *quantum entanglement*. This phenomenon, which *Erwin Schrödinger* called *the characteristic trait of quantum mechanics*, describes a situation where two or more particles become linked in a single, inseparable state, regardless of the distance separating them [187]. If two particles are entangled, a measurement on one—determining its spin, for example—instantaneously defines the corresponding property of the other.

This demolishes the classical notion of *separability*—the idea that spatially distinct objects have their own independent, well-defined states. Entangled particles do not have individual states; they exist as a single, unified system until a measurement is performed. The relationship between them is, in a sense, more real than the properties of the individual parts. It suggests a profoundly interconnected or *non-local* reality that transcends our everyday experience of space, a conclusion experimentally verified by tests of Bell's theorem [183].

The Enduring Mystery: A "Philosophical Quagmire" The operational success of quantum mechanics is undeniable, yet its implications for the nature of reality remain deeply unsettling, even to its pioneers. As the celebrated physicist *Richard Feynman* candidly admitted, *"I think I can safely say that nobody understands quantum mechanics"* [185]. The theory works perfectly as a predictive tool, but the philosophical questions it raises have led to a "quagmire" of competing interpretations, each trying to make sense of the measurement problem. Among the leading contenders are:

1. The *Copenhagen Interpretation (Bohr/Heisenberg)*, which takes a pragmatic (or anti-realist) view, suggesting that questions about an "unobserved reality" are meaningless and that physics should only concern itself with the outcomes of experiments.

2. The *Many-Worlds Interpretation*, first proposed by *Hugh Everett III* in 1957. It posits that the wave function never collapses. Instead, every possible outcome of a quantum measurement actually occurs, each in a separate, branching universe. In this view, Schrödinger's cat is both alive *and* dead, but in different, equally real, worlds [188].

3. *Hidden-Variable Theories*, most famously developed by *David Bohm*. These theories restore realism and determinism, suggesting that particles always have definite properties, but they do so at the cost of embracing explicit non-locality [189].

These interpretations, among others, highlight that while we know *how* to use quantum mechanics with astounding accuracy, the debate over *what it means* for reality remains one of the most vibrant and profound frontiers in all of science.

The Quantum Conundrum: A New Reality The quantum revolution was more than a series of discoveries; it was a fundamental rupture in the Western scientific worldview. In probing the foundations of matter, physics found that reality dissolves into something ghostly and elusive. The solid, predictable objects of classical physics vanished, replaced by abstract **wave functions** governing probabilities. Key tenets of the old world were systematically dismantled: energy was found to be quantized [190], particles exhibited wave-like properties [191], and nature at its core was found to be irreducibly probabilistic [192].

Perhaps most profoundly, quantum mechanics upended the **Cartesian split** between the objective world and the subjective observer, a division that had underpinned science since the Enlightenment. As **Niels Bohr** argued, in any quantum experiment, the observer and the observed form an indivisible, inseparable whole [179, 193, 180, 182]. The properties of a quantum system are only defined in the context of the specific apparatus chosen to measure them. This is not a technical inconvenience but a deep truth about a participatory reality where, as **Pascual Jordan** noted, observation doesn't just disturb, it *creates* [194, 186].

A House Divided: The Interpretational Schism Faced with this crisis, the pioneers of physics splintered into competing philosophical camps, a division that persists to this day. The different reactions represent distinct attempts to build a coherent worldview from the strange new rules.

- *The Copenhagen Orthodoxy (Bohr & Heisenberg):* For decades, the dominant view was to accept the weirdness as fundamental. Bohr and his allies essentially argued that our classical intuitions are misleading and that physics should renounce the goal of describing an observer-independent "reality." [168, 180, 179, 169] Its task is simply to provide a consistent framework for predicting the outcomes of measurements.

- *The Realist Resistance (Einstein, de Broglie & Bohm):* Albert Einstein led the resistance, convinced that quantum theory was an incomplete, statistical approximation of a deeper, deterministic reality [178]. While Einstein's own "hidden variables" approach was eventually ruled out by experiment, his realist spirit was carried on by others. *Louis de Broglie* briefly proposed a "pilot-wave" theory in 1927 [191], an idea that was independently rediscovered and fully developed by American physicist *David Bohm* in 1952 [189]. *Bohmian mechanics* posits that particles have definite positions at all times but are guided by a real quantum wave, thus preserving realism at the cost of embracing explicit non-locality.

- *The Radical Alternatives (Everett & Wigner):* Other physicists proposed even more radical solutions. In his 1957 doctoral thesis, *Hugh Everett III* formulated the *Many-Worlds Interpretation*, which claims the wave function never collapses [188]. At the

more speculative end of the spectrum, mathematical physicist *John von Neumann* and Nobel laureate *Eugene Wigner* entertained the idea that the "collapse" is unique and is triggered by the intervention of a *conscious observer*, suggesting a special role for the mind in actualizing physical reality [195].

This enduring schism at the heart of quantum mechanics transcends historical significance to constitute a fundamental rupture in our comprehension of reality itself [186, 174, 180]. The philosophical confrontations between Bohr, Einstein, and their contemporaries were not conclusive battles but opening salvos that exposed a vast terrain of ever-deepening enigmas [182, 176]. Far from representing a resolved chapter in scientific history, these debates unveiled a foundational crisis whose reverberations permeate every frontier of contemporary theoretical physics [196].

The profound discord between quantum theory's extraordinary predictive success and the ambiguity shrouding its ontological implications casts long shadows across our attempts to unify physics [195, 183, 184]. This tension between mathematical formalism and conceptual understanding infiltrates our efforts to reconcile quantum principles with gravitation, to decode the nature of time and entropy, to illuminate cosmological origins, and to unveil the universe's hidden constituents [197, 19, 29]. The classical dichotomies—determinism against chance, locality against entanglement, participatory against objective reality—resurface as spectral presences within the great unsolved problems of our era [179, 169].

What emerges from this inheritance is a constellation of ten fundamental challenges, each representing a distinct manifestation of this deeper crisis. These modern "clouds on the horizon" demand not incremental refinement of existing frameworks but a radical reconceptualization of the architectural foundations upon which physics rests. They beckon us toward what may constitute the next profound scientific and philosophical revolution, one that must confront the unresolved legacy of the quantum upheaval that began a century ago [185, 174, 196]. These fundamental challenges are presented below:

1. The Riddle of Quantum Gravity At the heart of theoretical physics lies a deep chasm between its two greatest triumphs: Einstein's General Relativity, which describes gravity as the elegant curvature of a smooth spacetime, and Quantum Mechanics, which governs the microscopic world through probabilistic fields. The two frameworks are fundamentally incompatible. While quantum field theory successfully describes the electromagnetic, weak, and strong forces, gravity stubbornly resists quantization through conventional methods, leading to nonsensical, infinite results. This quest for a unified theory of *quantum gravity* is a necessary step to understand the universe's most extreme environments, such as the singularity within a black hole or the very first moment of the Big Bang. This challenge has spawned a rich landscape of theoretical approaches, from leading research programs like *string theory*, which posits that fundamental particles are vibrations of tiny strings [198, 199, 200, 201], to *loop quantum gravity*, which suggests spacetime itself is composed of discrete, quantized chunks [8, 3]. More exotic proposals include *causal dynamical triangulations* [202] and *emergent spacetime* frameworks, which suggest that geometry itself arises from the entanglement of quantum information [1, 2].

2. The Ghost in the Quantum Machine Despite its spectacular predictive success, quantum mechanics harbors a deep interpretational enigma that has persisted since its inception: the *measurement problem*. This problem asks what it truly means to observe a quantum system, a process that seemingly forces a particle to abandon a ghostly superposition of multiple states and commit to a single, definite outcome through the *"collapse"* of the wavefunction. Whether the wavefunction—the mathematical object describing this superposition—is a real physical entity or merely a statement of our knowledge remains a subject of fierce debate, an ambiguity that strikes at the core of our understanding of reality itself [203]. Various interpretations compete for ontological primacy, each with profoundly different implications for the nature of reality and observation. These frameworks range from the *Many-Worlds Interpretation*, which posits that all possible outcomes occur in branching, parallel universes [204], and the hidden variables of *Bohmian mechanics* [205, 206], to more subjective frameworks like *Quantum Bayesianism (QBism)*, which treats quantum probabilities as an observer's personal beliefs [207], and *spontaneous collapse models* that propose physical mechanisms for the collapse [208].

3. The Dark Side of the Cosmos One of the most humbling discoveries in cosmology is that the familiar matter described by the Standard Model of particle physics constitutes a mere 5% of the universe. The cosmic ledger reveals a startling 95% deficit, an invisible "dark sector" whose existence is only inferred through its distinct gravitational effects. *Dark matter*, a mysterious, non-luminous substance, provides the unseen gravitational scaffolding that shapes galaxy rotation curves and cosmic structure formation [136]. Particle physics offers numerous candidates for it, from *Weakly Interacting Massive Particles (WIMPs)*, extensively searched for in underground detectors [209], to *axions* that might be detected via their conversion to photons in strong magnetic fields [210]. Meanwhile, *dark energy* is the enigmatic force driving the universe's accelerating expansion. Its nature remains even more mysterious, with possibilities ranging from Einstein's *cosmological constant*—whose observed value is so unnaturally small it represents a major theoretical puzzle [211]—to dynamic *quintessence* fields or even *modifications of general relativity* itself [212, 213].

4. The Arrow of Time The *arrow of time* presents a fundamental puzzle: while the microscopic laws of physics are almost entirely time-symmetric, our macroscopic reality is built upon a relentless, forward march from past to future. This asymmetry, or the distinction between past and future, seems to emerge only through the lens of thermodynamics, where the inexorable increase of entropy (disorder) provides a clear directionality. This suggests that time may not be a fundamental aspect of reality but rather an emergent property arising from a deeper, timeless layer of physics [197]. Contemporary research increasingly supports this view, with approaches ranging from *relational theories* where time arises from change itself [214] to proposals where it emerges from *quantum entanglement dynamics* [215]. Other frameworks in quantum gravity explore time as a product of more primitive structures, as seen in *causal set theory* [216], or as a consequence of quantum information flow and *decoherence* [170].

5. The Problem of Naturalness and Cosmic Fine-Tuning In the architecture of the universe, certain numbers appear to be exquisitely "fine-tuned", posing the *hierarchy problem*: why is gravity astonishingly weak compared to the other fundamental forces, and why is the mass of the Higgs boson so much lighter than the natural energy scale where quantum gravity effects should dominate? For decades, physicists suspected that a new principle like *supersymmetry* would provide an elegant, "natural" solution by introducing partner particles that stabilize the Higgs mass [217]. However, the resounding silence from experiments at the Large Hadron Collider, which have failed to find evidence for such new physics, has triggered a deep, philosophical crisis. This has forced physicists to reconsider *naturalness* itself as a guiding principle for theory-building [218, 219]. Consequently, alternative proposals are being explored with renewed interest, including *technicolor models* [220], scenarios where the Higgs is a composite particle, and *anthropic reasoning* within holocosmos frameworks [221].

6. The Arbitrary Elegance of the Standard Model The *Standard Model* of particle physics is a monumental achievement, describing the known elementary particles and their interactions with stunning precision. Yet, for all its predictive power, its structure appears remarkably arbitrary and "baroque", crying out for a deeper organizing principle. It fails to explain why its governing symmetries are the specific group $SU(3) \times SU(2) \times U(1)$, why fundamental particles are organized into three redundant "generations" of increasing mass, or why its nineteen "free parameters"—such as particle masses—have the values they do. This apparent lack of aesthetic simplicity has led physicists to explore possibilities like *Grand Unification Theories (GUTs)*, which seek to merge the three forces into a single, unified force within a larger symmetry group [222]. Other directions include *extra-dimensional models* that seek geometric explanations for particle properties [223] and more abstract approaches using algebraic selection principles like *spectral triples* [224] or other categorical frameworks [225].

7. The Moment of Creation Our cosmological narrative confronts us with the puzzle of *initial conditions*: the Big Bang theory leads back to an initial *singularity*—a moment of infinite density where the known laws of physics break down. This presents two profound problems: what physics governs the universe's birth at or "before" this moment, and why did our universe begin in an extraordinarily *low-entropy*, highly ordered state, a configuration necessary for the subsequent emergence of complex structures like galaxies and stars? Models of *cosmic inflation* partially address the uniformity problem [88, 226], but they do not eliminate the initial singularity itself. Resolving this requires a theory of quantum gravity, leading to various proposals including the *Hartle-Hawking no-boundary proposal* [51], *Penrose's conformal cyclic cosmology*, which recycles universes through infinite cycles [227], and *loop quantum cosmology's* bounce scenarios, which avoid the singularity entirely by suggesting the Big Bang was a "Big Bounce" from a previous cosmic phase [228].

8. The Substance of Reality: Fields, Particles, and Information While modern physics often describes reality as a tapestry of fields where particles are merely localized excitations, the ontological status of these concepts remains surprisingly unsettled. A profound question asks whether fields, particles, and even spacetime itself are truly fundamental or if they are emergent properties of a deeper, more abstract structure. Recent theoretical advances,

particularly the *holographic principle* and the *AdS/CFT correspondence*, lend significant weight to this idea by suggesting that a theory of gravity within a bulk volume can be equivalent to a quantum theory on its boundary [140]. This has fueled the *"It from Qubit"* movement, which speculates that the geometry of spacetime is woven from the fabric of quantum entanglement. This notion is explored through approaches like *tensor networks*, which model spacetime geometry using entanglement patterns [229], and more abstract *categorical and operator-algebraic reformulations* of quantum field theory [230], all hinting that our familiar reality may be an effective description of more primitive, information-based relationships.

9. The Black Hole Information Paradox Black holes are the ultimate theoretical laboratories, presenting a stark clash between general relativity and quantum mechanics that is crystallized in the *black hole information paradox*. In 1976, Stephen Hawking showed that black holes slowly evaporate by emitting thermal radiation, creating a profound conflict: quantum mechanics' principle of *unitary evolution* insists that information can never be destroyed, yet Hawking's calculation suggested it vanishes as the black hole disappears. The fate of this information touches the foundations of both theories and has driven research for decades, leading to further puzzles like the *firewall paradox*, which suggested violent physics at the event horizon [231]. Very recent breakthroughs, however, now point toward a resolution. The development of *quantum extremal surfaces* [232] and the *"island formula"* [139] suggest that information does escape, intricately encoded in the outgoing radiation through subtle gravitational effects and entanglement structures not captured in the original analysis [233].

10. The Ascent from Reductionism While the traditional scientific method of *reductionism*—understanding a system by breaking it down into its smallest components—has been phenomenally successful, many of today's deepest challenges suggest we may be reaching its limits. This has led to a paradigm shift toward *emergence*, driven by the ultimate goal of moving *beyond* describing the universe's laws to the deeper task of *explaining* why they take the specific form they do [234]. This approach asks whether spacetime, particles, and forces can be derived from more primitive, relational, or information-theoretic principles rather than simply being postulated. This speculative frontier includes deriving physics from quantum information, famously captured by John Wheeler's "it from bit" philosophy [235], as well as process-based approaches like *causal set theory* [236]. Other frameworks pursue an *algebraic reconstruction* from symmetry or cohomological data [237] or employ the tools of *categorical field theories* [238], all sharing the tantalizing hope that the universe's apparent complexity may emerge from surprisingly simple, perhaps even inevitable, foundational principles.

The Quest for Unification The enduring quest to reconcile quantum mechanics and general relativity—to unify the probabilistic, relational world of the very small with the dynamical geometry of the very large—remains the most profound challenge in theoretical physics. Any successful theory must ultimately dispense with the notion of a fixed background, revealing spacetime itself as an emergent phenomenon. This work introduces the Interdependent Quantum Reality (IQR) framework, a paradigm grounded in a deeply relational and operator-theoretic ontology. We posit that physical reality emerges from a pre-geometric substrate: a

continuum of structured, operator-valued singularities termed *Primordial Quantum Singularities*. The coherence and dynamics of this continuum are governed by a single, non-factorizable Quantum Holo-State, $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27), from which all emergent structures, including the fabric of spacetime and the matter within it, are derived.

The Fundamental Incompatibility The necessity for such a background-independent approach stems from a fundamental conflict at the heart of physics. General Relativity teaches us that spacetime is a *dynamic actor*—a malleable, geometric fabric whose curvature tells matter and energy how to move, while matter and energy in turn tell spacetime how to curve [239]. This self-consistent feedback loop is the essence of Einstein's theory. In stark contrast, standard Quantum Field Theory treats spacetime as a *fixed, rigid stage*—a static background upon which quantum fields interact and evolve [82].

Herein lies an irreconcilable difference: the stage cannot be both a dynamic participant and a passive, non-participating backdrop. A true theory of quantum gravity must therefore be formulated in a framework where the geometric stage itself is subject to quantum principles. A fixed background is, by definition, a classical object immune to quantum effects—a proposition that is physically untenable at the most fundamental level.

Resolution Through Emergence This theoretical impasse leads to concrete failures in our ability to describe the universe at its most extreme scales. General Relativity predicts its own demise at singularities, points where the curvature of spacetime becomes infinite and the laws of physics cease to apply [240]. A theory built upon a smooth, fixed background cannot describe the physics at or beyond such points.

The formalism, the Interdependent Quantum Reality (IQR) framework, presented in this treatise emerged to address the fundamental incompatibility between general relativity's dynamic spacetime and quantum field theory's fixed background stage [82]. This conflict manifests most acutely at classical singularities where general relativity predicts its own demise [240], and in the quantum superposition principle which demands that massive objects in superposition must induce superposed spacetime curvatures—a concept incompatible with any fixed background. The IQR resolves these paradoxes through a radical reconceptualization: spacetime is not fundamental but emerges from a pre-geometric substrate called the $\hat{\Omega}$-Continuum (Definition 4.617), populated by elementary quantum singularities. When classical physics reaches its limits at what would traditionally be called singularities, there is no catastrophic breakdown but rather a transition to this pre-geometric regime where the relational algebra of Primordial Quantum Singularities governs reality.

At the heart of this theory lies the Primordial Quantum Singularity ($\mathfrak{B}_x$), a structured, operator-valued entity that serves as the fundamental, indivisible unit of quantum-relational structure (Definition 1.25). Each PQS is characterized by its internal architecture:

$$\mathfrak{B}_x := {}_{\hat{\mathbf{\Phi}}_x}\mathring{\mathbf{\Lambda}}_{x,\hat{\mathbf{\Theta}}_x}$$

where $\hat{\mathbf{\Phi}}_x$ and $\hat{\mathbf{\Theta}}_x$ are the *Gaiamiti* (Definition 6.2) and *Tantrakyma* (Definition 6.3) operator fields respectively, unified through the intrinsic duality operator $\mathring{\mathbf{\Lambda}}_x$ that encodes fundamental dualities, superposition, entanglement, and symmetries. These are not singularities in the

classical sense of infinite density, nor are they defined by location in a pre-existing spacetime. Rather, they are operator-valued, field-embedded "quantum grains" of reality, each existing at a locus in the foundational continuum but deriving their meaning entirely through their relational connections to all other PQSs [3].

The coherence of this quantum universe is maintained through a single, non-factorizable Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27), which represents the framework's most profound innovation. This state transcends the conventional quantum mechanical paradigm—it is not a state within a pre-existing Hilbert space but rather generates the Hilbert space structure itself through the Gelfand-Naimark-Segal construction (Definition 1.34) applied to the global operator algebra [230, 241]. The non-factorizability of this universal state is essential: it ensures that every PQS is intrinsically entangled with every other, creating a cosmic tapestry where each quantum singularity defines its existence only through its reflection of all others, analogous to the jewels in Indra's Net [242].

Part I

Foundations

Chapter 1

The Fourfold Algebra and The Singularity

1.1 Introduction

At the heart of modern theoretical physics lies a fundamental contradiction. General Relativity describes spacetime as a dynamic actor, a malleable fabric that dictates how matter moves while matter tells it how to curve [239, 146, 7]. In stark contrast, Quantum Field Theory treats spacetime as a fixed, passive stage upon which quantum events unfold [82, 243]. The central problem is that these two most successful frameworks cannot both be universally correct: one treats spacetime as a dynamical field, the other as an inert backdrop. This work proposes to resolve this impasse by advancing the principle that spacetime is not fundamental, but an emergent property of a deeper, purely quantum–relational reality — an idea that resonates with contemporary research suggesting geometry is woven from the fabric of quantum entanglement [1, 2]. The construction is precise enough to yield a complete Hamiltonian formulation and a background–independent unification of gravity and quantum mechanics.

The treatise develops this principle through the **Interdependent Quantum Reality (IQR) framework** [3, 14]. Within this framework, the fundamental stratum of reality is a relational fibred-network of entangled *Ultra-Sub-Planckian* (Section 4.15.3) *Primordial Quantum Singularities* (PQSs) (Definition 1.25), whose coherence is governed by a single **Quantum Holo-State**, $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27) [244, 245]. The PQS is the loci where times and spaces become unified and indistinguishable [246, 8, 3]. The treatise constructs a triad of independent times: (1) **entanglement phase time** (Section 4.12.1) that quantifies the phase-coherent evolution of entangled modal structure between two PQS loci [170], (2) **vacuum response time** (Section 4.12.3) that characterizes the temporal sensitivity of the vacuum structure to relational displacements [244, 245], and (3) **spectral shear time** (Section 4.12.5) measures a form of quantum "temporal tension" arising from the algebraic structure of the underlying reality [4, 5]. In a similar manner, the treatise also introduces a triad of independent distances: (1) **correlator distance** (Section 4.9.1) is a measure of the magnitude of the quantum signal between two singularities [247], (2) **spectral distance** (Section 4.9.6) is a measure of separation in quantum geometry calculated from the intrinsic "friction" between the operators for change and relational structure [4], and (3) **vacuum-response distance** (Definition 4.463) [244].

To formalize this emergent geometry, the treatise organizes these triadic measures into a

relational phase-geometry bundle (Definition 4.604) [248, 249]. This elegant mathematical structure attaches to every point in the fundamental *quantum configuration space*, $\mathcal{X}_q$, (Section 4.19.3) a fiber (eq. (4.288)) that encodes its complete relational identity. Each fiber $\mathfrak{F}_x$ is a hybrid space that mathematically formalizes the union of distinguishability and temporal flow:

$$\mathfrak{F}_x := \mathcal{F}_x^{\text{dist}} \times \mathcal{F}_x^{\text{time}}.$$

Here, the *distinguishability fiber* $\mathcal{F}_x^{\text{dist}}$ (Definition 4.599) contains the three-dimensional vector of distances, while the orthogonal *temporal flow fiber* $\mathcal{F}_x^{\text{time}}$ (Definition 4.600) contains the vector of corresponding times. This construction provides a profound and rigorous definition for the Primordial Quantum Singularity itself: it is precisely the locus where the distance and time vectors between any two points vanish simultaneously, rendering them relationally indistinguishable (Corollary 4.601). Thus, the very fabric of spacetime is woven from this dynamic bundle, a scaffold upon which quantum analogues of connection and curvature can be defined (Section 4.16) [4]. Consequently, what we perceive as "distance," "duration," and "curvature" are not fundamental, but are macroscopic, statistical averages of the underlying quantum-informational relationships between these foundational units. These units derive their meaning entirely from their interrelations, a concept at the heart of relational quantum mechanics [3].

This web of interrelations is physically realized within the foundational stratum of reality: the **fibred continuum of primordial quantum singularities**, $\mathcal{C}_d$, which is formally defined as the set of all such structured singularities (Definition 4.617) [248, 249]:

$$\mathcal{C}_d := \left\{ \mathfrak{B}_{\vec{r}},\ \hat{\Omega}_{\vec{r}},\ \mathfrak{F}_{\vec{r}} \right\}_{\vec{r} \in \mathcal{C}_d}.$$

This expression defines the continuum as a smooth manifold where every point $\vec{r}$ is itself a structured PQS ($\mathfrak{B}_{\vec{r}}$), containing a singularity code ($\hat{\Omega}_{\vec{r}}$) and hosting a fiber of relational information ($\mathfrak{F}_{\vec{r}}$) with ultra-sub-Planckian support (Section 4.18, eqs. (4.199) and (4.303), and Principle 4.1) [4]. The very *quantum configuration space* $\mathcal{X}_q$, which serves as the base for the Relational Phase-Geometry Bundle, then emerges as a quotient space from this continuum (Proposition 4.625) [248, 249]. This emergence is enacted by an equivalence relation where all points within a single Primordial Quantum Singularity—being operationally indistinguishable as their relational distance and time vectors vanish (Definitions 4.599 and 4.600 and Corollary 4.601)—are identified as a single, unique point in $\mathcal{X}_q$. Thus, the arena for physics is itself a relational construct, born from a deeper reality where each point is a self-contained universe of potential. Yet mathematics itself insists that to define such a point is already to define what it is not. This reciprocity, latent in the geometry of the Relational Phase–Geometry Bundle, is the first hint of a deeper structural necessity: no entity — not even the cosmos in its entirety — can be specified without simultaneously specifying its complement. This observation will lead us directly to the Axiom of Duality, the principle that governs the interplay between self-containment and dependence at every scale of reality [3].

For this emergent arena to serve as a valid stage for physical dynamics, it must possess a coherent and well-defined mathematical structure. The treatise establishes this by defining the **quantum configuration space**, $\mathcal{X}_q$, as the quotient space of the foundational continuum,

$\mathcal{C}_d$ [248, 249]:

$$\mathcal{X}_q := \mathcal{C}_d/\sim$$

where the equivalence relation $\sim$ identifies all points within a single Primordial Quantum Singularity as one (Proposition 4.625). Through the formal application of the *Quotient Manifold Theorem* (Section 4.19.3) [248, 249], this emergent space inherits a smooth manifold structure from the foundational continuum. Consequently, the familiar smooth stage of physics is shown to be a consistent, macroscopic manifestation of the underlying relational coherence [3], retaining the full cardinality of the continuum (Proposition 4.637) while being grounded in a purely operator-theoretic foundation [4].

Given the triadic notion of distance, it is now possible to define the very instrument that imparts a geometric structure onto the emergent quantum configuration space: the **Operator-Valued Emergent Metric Tensor**, $\hat{g}_{\mu\nu}(x)$ (Definition 5.1) [4, 5]. This tensor is not fundamental but is itself emergent, defined as the second **Fréchet variation** of the squared composite distance operator, $D^2(x, x')$, evaluated at the coincidence limit:

$$\hat{g}_{\mu\nu}(x) := \frac{\partial^2}{\partial x^\mu \partial x'^\nu} D^2(x, x')\Big|_{x'=x}.$$

where

$$D^2(x, x') := \hat{d}^2_{\text{corr}}(x, x') + \hat{d}^2_{\text{vac}}(x, x') + \hat{d}^2_{\text{spec}}(x, x'). \tag{1.1}$$

Each $\hat{d}_a(x, x')$ for $a \in \{\text{corr}, \text{vac}, \text{spec}\}$ is a Hermitian operator on $\mathcal{H}_{\text{total}}$. Unlike a classical metric, this defines $\hat{g}_{\mu\nu}(x)$ as a field of Hermitian, positive semi-definite operators, encoding the infinitesimal geometry in the language of quantum mechanics [244, 245]. A profoundly significant feature is that it inherits the triadic structure of its origins, decomposing into correlational, vacuum, and spectral layers, hinting at a non-Riemannian, triadic noncommutative geometry [4, 5]. The bridge to the classical world is crossed when this operator is evaluated in the universal *Quantum Holo-State*, yielding the familiar metric tensor $\bar{g}_{\mu\nu}(x)$ as its expectation value (Definition 5.10) [3]. Thus, $\hat{g}_{\mu\nu}(x)$ is the fundamental link, translating the rich, multi-layered quantum relational data with its ultra-sub-Planckian support into the smooth, curved spacetime we perceive.

Complementing the metric tensor that governs emergent space, the framework defines its temporal analogue: the **operator-valued temporal curvature tensor**, $\hat{t}_{\mu\nu}(x)$ (Definition 5.17) [4, 5]. In a perfectly parallel construction, this tensor arises not from distance but from the triadic operators of relational time. It is formally defined as the second Fréchet variation of the squared composite temporal displacement, $T^2(x, x')$, at the coincidence limit:

$$\hat{t}_{\mu\nu}(x) := \frac{\partial^2}{\partial x^\mu \partial x'^\nu} T^2(x, x')\Big|_{x'=x}.$$

where

$$T^2(x, x') := \hat{t}^2_{\text{corr}}(x, x') + \hat{t}^2_{\text{vac}}(x, x') + \hat{t}^2_{\text{spec}}(x, x'),$$

is the squared norm of the operator-valued triadic temporal vector, as defined in the temporal fiber structure of $\mathfrak{F}_x$ (Definition 4.600) [244, 245]. Crucially, this is **not a metric**. Rather than encoding distance, this field of Hermitian operators quantifies the curvature of relational

quantum phase flow [3]. It measures the directional sensitivity of phase displacement to coordinate separation, providing the dynamic, temporal component of the emergent geometry. Together, the metric tensor $\hat{g}_{\mu\nu}(x)$ and the temporal curvature tensor $\hat{t}_{\mu\nu}(x)$ form the two halves of the complete, unified *Chronogeometric Operator*, $\hat{\Sigma}_{\mu\nu}(x)$ [4].

The companionship of the spatial metric and the temporal phase-flow is now consolidated into a single, comprehensive object that captures the total infinitesimal structure of the emergent geometry: the **Operator-Valued Relational Chronogeometric Operator**, $\hat{\Sigma}_{\mu\nu}(x)$ (Definition 5.25) [4, 5]. Defined as the sum $\hat{\Sigma}_{\mu\nu}(x) := \hat{g}_{\mu\nu}(x) + \hat{t}_{\mu\nu}(x)$, this operator represents the complete description of spacetime at the fundamental, quantum level. The bridge to the classical world is crossed when this unified operator is evaluated in the *quantum holo-state*, yielding the macroscopic *chronogeometric tensor*, $\bar{\Sigma}_{\mu\nu}(x)$ [244, 245]. This emergence is made mathematically precise by the foundational equation of the theory:

$$\bar{\Sigma}_{\mu\nu}(x) = \langle \overset{\circ}{\boldsymbol{\Psi}} | \hat{\Sigma}_{\mu\nu}(x) | \overset{\circ}{\boldsymbol{\Psi}} \rangle = \langle \overset{\circ}{\boldsymbol{\Psi}} | \left(\hat{g}_{\mu\nu}(x) + \hat{t}_{\mu\nu}(x) \right) | \overset{\circ}{\boldsymbol{\Psi}} \rangle.$$

The central ambition of this theory—the unification of general relativity and quantum mechanics—is concisely expressed by this relationship, which establishes the Chronogeometric Tensor, $\bar{\Sigma}_{\mu\nu}(x)$, as a mathematical bridge, explicitly connecting the classical world of gravitation with the fundamental reality of quantum mechanics [3, 14]. The left-hand side, the **Chronogeometric Tensor** $\bar{\Sigma}_{\mu\nu}(x)$, represents the domain of general relativity. It is a classical, macroscopic field that describes the smooth, curved spacetime we perceive as the stage of the cosmos. The right-hand side represents the fundamental quantum reality from which this classical world emerges. It is composed of three essential quantum-mechanical ingredients:

1. The **quantum holo-state** $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ (see Definition 1.27), the fundamental ontological quantum state that describes the entire universe [3].

2. The **chronogeometric operator** $\hat{\Sigma}_{\mu\nu}(x)$ (see Definition 5.26), the underlying quantum-geometric entity, whose properties are operator-valued subject to quantum principles that are liberated from fixed classical numbers [4, 5].

3. The **expectation value** prescription, $\langle \cdot | \cdot | \cdot \rangle$, is the core mathematical procedure for deriving a measurable, classical outcome from the quantum substrate [14].

The equality in this expression is therefore a profound statement of emergence, a principle visually summarized by annotating the equation's components:

$$\underbrace{\bar{\Sigma}_{\mu\nu}(x)}_{\text{General Relativity}} \quad = \quad \underbrace{\langle \overset{\circ}{\boldsymbol{\Psi}} | \hat{\Sigma}_{\mu\nu}(x) | \overset{\circ}{\boldsymbol{\Psi}} \rangle}_{\text{Quantum Mechanics}}$$

This equation declares that the classical spacetime of general relativity ceases to be a separate or fundamental entity, becoming instead, with mathematical exactness, the macroscopic statistical average of the deeper quantum reality described by the Interdependent Quantum Reality (IQR) framework [3, 4, 5]. This is the heart of the matter: *spacetime geometry is a property of the quantum state*, not the container for the state. The dynamic, chronogeometric nature of reality is therefore a direct consequence of the underlying quantum-informational

relationships [3]. This concept finds a poetic analogue in the metaphor of **Indra's Net**, where each jewel defines its existence only through its reflection of every other [242]. Similarly, the chronogeometry of the universe is a tapestry woven from the threads of entanglement connecting every Primordial Quantum Singularity. To presuppose a fixed background would be akin to demanding that this net be hung upon an external scaffold, when the profound truth is that the relational fabric of cosmic reality supports itself.

The chronogeometric fabric described by the Quantum Holo-State emerges from a pre-geometric and pre-time substrate [3]. The foundation of the Interdependent Quantum Reality (IQR) framework is the $\hat{\mathbf{\Omega}}$–Continuum (Definitions 1.25 and 4.617), a smooth, Hausdorff continuum $\mathcal{C}_d$ with cardinality $\mathfrak{c}$ isomorphic to the Reals ($\mathcal{C}_d \cong \mathbb{R}$) [248, 249]. This continuum is composed of fibred **primordial quantum singularities** (PQSs), $\mathfrak{B}_{\vec{r}}$, with each PQS defined as:

$$\mathfrak{B}_{\vec{r}} := \hat{\mathbf{\Omega}}_{\vec{r}} := \overset{\circ}{\mathbf{\Lambda}}_{\vec{r},\hat{\Theta}_{\vec{r}}}$$

where the components are the local instantiations of three entities novel to the IQR theory: the *Gaiamiti field* $\hat{\mathbf{\Phi}}_{\vec{r}}$ (Definition 6.118), the *Tantrakyma field* $\hat{\mathbf{\Theta}}_{\vec{r}}$ (Definition 6.142), and the **fourfold dialectic algebra of symmetry** $\overset{\circ}{\mathbf{\Lambda}}_{\vec{r}}$ (Section 1.2.7) [4, 5].

The proposed existence of these two novel fundamental fields, the Gaiamiti and the Tantrakyma, govern the emergence of all physical phenomena from this substrate. The **Gaiamiti Field**[1] (Definition 6.2) is a Hermitian, operator-valued field that generates the relational chronogeometry; its quanta, the *apeirons*[2] (see Section 9.17.1), are the progenitors of the long sought-after **graviton**, which arises as the massless Goldstone mode from the **spontaneous symmetry breaking of the Gaiamiti field potential** (Sections 9.17 and 9.17.2) [14].

In parallel, the **Tantrakyma Field**[3] (Definition 6.3) is the fundamental operator-valued field governing the excitation, modulation, and internal symmetry structure of the PQSs across the emergent quantum configuration space $\mathcal{X}_q$ (see Section 4.19.3); its quanta, the *kymons* (see Section 9.18.5), are the progenitors of the **Higgs boson** and the **Standard Model gauge group**, which emerge from the **symmetry breaking of the Tantrakyma field potential around its vacuum expectation value** (VEV) (Sections 9.18.5, 9.18.6 and 12.4) [14], with the particles of the Standard Model manifesting as the various excitations of this broken symmetry.

The *Fourfold Dialectic Algebra of Symmetry*, $\overset{\circ}{\mathbf{\Lambda}}_{\vec{r}}$, serves as the logical blueprint (Defini-

[1] **Gaiamiti** is a compound word of Greek and Sanskrit origin, where **Gaia** (from the Greek Ga ia), invokes the name of the primordial Greek goddess of the Earth, described in classical sources as a foundational entity from which other deities and the physical world emerged [250, 251, 252], and **miti**, is taken from the Sanskrit word **Jyāmiti** (Skt. *Jyāmiti*), which translates to "geometry" [66]. This term itself is a compound of *jyā*, meaning "bowstring," and *miti*, meaning "measure."

[2] **Apeiron** (*Ápeiron*) is the "The Unlimited" or "The Indefinite"; A concept first articulated by Anaximander but central to Pythagorean cosmology. The *apeiron* (*ápeiron*) is the boundless, formless, indefinite primordial substance. The ordered universe (cosmos) comes into being when this unlimited substrate is acted upon and shaped by a principle of "limit" or "form" (*peras*, *péras*) [69, 72, 70, 71].

[3] **Tantrakyma** fuses तन्त्र (*tantra*, "warp, framework; that by which [threads are stretched/laid out]")—as established in classical lexica and modern overviews [66, 74, 75]—with κῦμα (*kyma*, "wave") in classical Greek [80]. The compound denotes a "woven-wave framework": oscillatory modes (waves) organized by an underlying rule-bound warp (framework).

tion 1.16). This algebra serves as the *a priori* "generative grammar" of reality, dictating the necessary modes of Symmetry, Antisymmetry (Section 2.1), Parasymmetry (Definitions 2.85 and 2.94), and Holosymmetry (Sections 2.3 and 3.8) that arise from the foundational Axiom of Duality (Sections 1.2.6, 14.1.3 and 17.3.1) [3]. This abstract logical framework is given its concrete "vocabulary" in the complete *Algebra of Observables*, $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32) [4, 5].

This algebraic formulation represents a profound reordering of physical ontology; it posits that the abstract C^*-algebra of observables, $A(C_d)$, is more fundamental than any pre-existing spacetime or Hilbert space [4, 5]. This is the representation-independent "language" of reality, existing prior to any notion of distance or time. The crucial step is the transition from this abstract set of rules to the concrete arena where physical dynamics can unfold. This arena is the **Algebra of Endomorphisms**, $\mathrm{End}(\mathcal{H}_{\mathrm{em}})$ (Definition 6.113), which is rigorously defined as the **Banach space of bounded operators**, $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$, (Definition 6.111) acting on the emergent Hilbert space, $\mathcal{H}_{\mathrm{em}}$, of the universe:

$$\mathrm{End}(\mathcal{H}_{\mathrm{em}}) := \mathcal{B}(\mathcal{H}_{\mathrm{em}}),$$

Its structure is chosen for physical and mathematical necessity. As a **Banach space**, it is complete under the *operator norm*—a measure of an operator's maximum "stretching factor"—ensuring a well-behaved and stable calculus for all operator-valued fields [253]:

$$\|A\|_{\mathrm{op}} := \sup_{\substack{\psi\in\mathcal{H}\\ \psi\neq 0}} \frac{\|A\psi\|}{\|\psi\|}.$$

Furthermore, it is a C^***-algebra** because it is equipped with the crucial *adjoint map* ($A \mapsto A^\dagger$) (Definition 6.112), an involution whose defining relation is the bedrock of quantum measurement:

$$\langle\psi|A\phi\rangle = \langle A^\dagger\psi|\phi\rangle.$$

This property is what allows for the existence of self-adjoint operators corresponding to physical observables. To compare these operators across the emergent manifold, the framework also derives an **Operator Bundle Connection**, $A_\mu(x)$ (Definition 6.192). This is an intrinsic gauge field that governs the parallel transport of quantum information, transforming to ensure physical laws remain consistent from point to point:

$$\mathcal{A}_\mu(x) \mapsto U(x)\mathcal{A}_\mu(x)U^\dagger(x) + i\,U(x)\partial_\mu U^\dagger(x).$$

The profound question of how the abstract *language* of the Algebra of Observables is translated into a concrete and fully equipped *arena* is answered by the theory's central mechanism of emergence: the **Gelfand-Naimark-Segal (GNS) construction** (Sections 1.4 and 1.4.1) [254, 230]. This process is the mathematical embodiment of physical actualization, a three-act story of how a coherent reality is built from a pre-geometric foundation.

First, the theory posits the **Abstract Algebra of Observables**, $A(C_d)$, as the foundational reality (Definition 1.32). This is the complete, representation-independent *"language"* of the universe, containing all possible physical relationships before any notion of a space for them to exist in has been defined [4, 5]. Second, the **Quantum Holo-State**, $|\Psi\rangle$, acts as the *"principle of cosmic selection."* It is represented as a pure state functional (Definition 1.34),

$$\omega^\Psi : A(C_d) \to \mathbb{C},$$

which reads the abstract script and assigns a definite expectation value to every potential observable, thereby selecting one coherent performance from the infinite possibilities.

Finally, the GNS construction serves as the mathematical engine that takes the algebra and the state and from them, generates the manifest reality as a unique **GNS Triplet** (H^{Ψ}, π^{Ψ}, $|\Omega_{GNS}\rangle$) (Definition 1.34) [254, 230]:

1. **The Stage (The Emergent Hilbert Space, H_{em}):** A bespoke arena whose very inner product is defined by the state (Definition 4.287):

$$\langle [A], [B] \rangle := \omega^{\Psi}(A^{\dagger}B)$$

,

2. **The Actors (The Representation, π):** A map,

$$\pi^{\Psi} : A(C_d) \to \mathcal{B}(\mathcal{H}_{\text{em}})$$

, that realizes the abstract observables as concrete, bounded operators acting on the Hilbert space via the rule $\pi^{\Psi}(A)[B] := [AB]$ (Definition 1.34),

3. **The Protagonist (The Cyclic Vector, $|\Omega_{GNS}\rangle$):** The concrete vector that embodies the Quantum Holo-State, from which all expectation values are recovered through the core relation:

$$\omega^{\mathring{\mathbf{\Psi}}}(A) = \langle \Omega_{\text{GNS}} | \pi^{\mathring{\mathbf{\Psi}}}(A) | \Omega_{\text{GNS}} \rangle.$$

This reveals a profound insight of our framework: the quantum state of the universe is the very architect of its own domain, not an ordinary inhabitant of a pre-existing container (Remark 1.36). The state functional defines the very geometry of the Hilbert space it inhabits. The **Fourfold Dialectic Algebra** (Definition 1.16) provides the axiomatic rules of construction, and the GNS construction is the act of building a coherent universe according to those rules. This process is the mathematical realization of true background independence, where the universe's quantum state and its arena of existence emerge as inseparable aspects of a unified, self-determining whole (Remark 1.37) [3].

This connection is made mathematically concrete through the definition of the inner product, which is *derived* from the system's fundamental correlations and not assumed. For any two modal states $|\psi_1\rangle_x, |\psi_2\rangle_x$ in the local Hilbert space $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$, their inner product is defined via the **Fourfold Inter-Modal Correlator**, $\hat{G}_{\Lambda}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]$ (Definition 4.9), evaluated in the Quantum Holo-State:

$$\langle \psi_1 | \psi_2 \rangle_{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}} := \lim_{x' \to x} \langle \mathring{\mathbf{\Psi}} | \hat{G}_{\Lambda}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] | \mathring{\mathbf{\Psi}} \rangle.$$

This is an operator-valued, gauge-covariant two-point function that quantifies quantum-relational correlations between any pair of internal modes in the complete *Fourfold Dialectic Algebra of Symmetry* of two Primordial Quantum Singularities, $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$ [230, 255, 3]. It defines a bounded linear operator on the total emergent Hilbert space $\mathcal{H}_{\text{em}}$ and provides the structural kernel for inter-PQS interference, "holomodal" entanglement, and emergent chronogeometry [4]. This formulation provides a physical mechanism for generating the

Hilbert space metric directly from the relational dynamics of the fundamental fields, as encoded in the Quantum Holo-State. The total emergent Hilbert space is then the disjoint union of all such locally generated spaces (Definition 4.228):

$$\mathcal{H}_{\text{em}} = \bigsqcup_{x \in \mathcal{X}_q} \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$$

To make the emergent inner product mathematically concrete, we must first define its core ingredients: the general quantum states that reside on each Primordial Quantum Singularity (PQS) and the operator that quantifies the relational connection between them. Any local modal quantum state within the IQR framework is described as a superposition of four fundamental ontological modes. A general state $|\psi\rangle_x$ at a locus x and another state $|\psi\rangle_{x'}$ at locus x' are thus expressed as a linear combination of these basis "vectors":

$$|\psi_1\rangle_x = \sum_\alpha c_{1\alpha} |\alpha\rangle_x, \qquad |\psi_2\rangle_{x'} = \sum_\beta c_{2\beta} |\beta\rangle_{x'},$$

where the indices α, β range over the four basis vectors. These vectors are the direct physical manifestation of the four logical vertices of the *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16):

$$\left\{ |\mathring{\mathbf{0}}\rangle,\ |\mathring{\mathbf{1}}\rangle,\ |\mathring{\mathbf{0}} + \mathring{\mathbf{1}}\rangle,\ |_{\mathring{\mathbf{0}}}\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{1}}}\rangle \right\}.$$

These basis vectors correspond, respectively, to the fundamental *Symmetric*, *Antisymmetric*, *Parasymmetric*, and *Holosymmetric* modes of reality. The relational link between two such states at different loci, $|\psi_1\rangle_x$ and $|\psi_2\rangle_{x'}$, is quantified by the *Fourfold Inter-Modal Correlator*. This operator, $\hat{G}_\Lambda$, is a bi-local (two-point) function that serves as the engine of relational dynamics, defining the structure of entanglement and interference across the $\hat{\mathbf{\Omega}}$–Continuum [3, 230, 255]. It is formally defined as (Definition 4.9):

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] := \sum_{\alpha,\beta} c_{1\alpha}^*\, c_{2\beta} \left(\hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x') \right).$$

The components of this correlator ensure that the relationship is well-defined across the emergent manifold. The operator $\mathcal{U}(x \leftarrow x'; \gamma)$ is the *gauge-covariant parallel transporter* [248, 256]. Its role is to connect the Hilbert space fibers at x' and x along a path γ within the emergent quantum configuration space $\mathcal{X}_q$. This guarantees that the calculated correlation is a true physical invariant, independent of the choice of local quantum reference frame.

The interplay between geometry and matter, the dance between the Gaiamiti and Tantrakyma fields, are consolidated into a single mathematical object. This *Generalized Field Operator* provides a unified representation of the total operator-valued content of each Primordial Quantum Singularity, expressed as a unified field vector [82, 14]:

$$\hat{\mathbf{F}}(x) := \begin{pmatrix} \hat{\mathbf{\Phi}}(x) \\ \hat{\mathbf{\Theta}}(x) \end{pmatrix}.$$

The complete relational dynamics of the system can then be explored by correlating this unified field with itself [230, 3]. This process naturally yields a 2×2 matrix structure, which

we call the *Field Correlator Matrix*:

$$\hat{\mathbf{G}}_{\text{field}}(x, x') = \begin{pmatrix} \hat{G}_{\mathbf{\Phi\Phi}}(x, x') & \hat{G}_{\mathbf{\Phi\Theta}}(x, x') \\ \hat{G}_{\mathbf{\Theta\Phi}}(x, x') & \hat{G}_{\mathbf{\Theta\Theta}}(x, x') \end{pmatrix}.$$

This matrix provides a complete map of the fundamental interactions. The *diagonal entries*, $\hat{G}_{\mathbf{\Phi\Phi}}$ and $\hat{G}_{\mathbf{\Theta\Theta}}$, describe the self-correlations, or internal dynamics, within the geometric and matter sectors, respectively. The *off-diagonal entries*, $\hat{G}_{\mathbf{\Phi\Theta}}$ and $\hat{G}_{\mathbf{\Theta\Phi}}$, represent the crucial interaction terms, quantifying the cross-correlation or "talk" between geometry and matter.

This 2×2 matrix, however, only describes the structure at the level of the fields [230, 14]. Each fundamental interaction must also respect the underlying logic of the *Fourfold Dialectic Algebra* [3, 4]. Consequently, each of the four entries in the Field Correlator Matrix is itself a 4×4 matrix, with components defined in the ontological basis of the four dialectical modes:

$$\hat{G}_{AB}(x, x') = \left[\hat{G}^{\alpha\beta}_{AB}(x, x')\right]_{\alpha,\beta\in\{0,1,p,s\}},$$

where each component $\hat{G}^{\alpha\beta}_{AB}$ corresponds to a transition between the ontological modes β and α within the fields A and B. This reveals the profound, multi-layered nature of a single relational link in the IQR framework. Each entry of the four components of the Field Correlator Matrix, $\hat{\mathbf{G}}_{\text{field}}$, is an operator on the total emergent Hilbert space, $\mathcal{H}_{\text{em}}$, and represents a distinct physical channel of relational correlation. Their formal definitions are constructed by specializing the generic field operator $\hat{\mathcal{F}}$ from the definition of the Fourfold Inter-Modal Correlator (Definition 4.9) to the specific Gaiamiti ($\hat{\mathbf{\Phi}}$) and Tantrakyma ($\hat{\mathbf{\Theta}}$) fields.

The Geometric Sector: $\hat{G}_{\mathbf{\Phi\Phi}}$ The *Geometric Correlator* describes the self-correlation of the Gaiamiti field [14, 230, 3]. It is the exclusive source of emergent geometry, defining how geometric potential propagates and relates to itself across the continuum. For general modal states $|\psi_1\rangle_x = \sum_\alpha c_{1\alpha}|\alpha\rangle_x$ and $|\psi_2\rangle_{x'} = \sum_\beta c_{2\beta}|\beta\rangle_{x'}$, it is defined as:

$$\hat{G}_{\mathbf{\Phi\Phi}}[\psi_1^*, \psi_2] := \sum_{\alpha,\beta} c^*_{1\alpha} c_{2\beta} \left(\hat{\mathbf{\Phi}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x')\, \hat{\mathbf{\Phi}}_\beta(x')\right)$$

The Matter Sector: $\hat{G}_{\mathbf{\Theta\Theta}}$ The *Matter Correlator* captures the self-relational structure of the Tantrakyma field [14, 230, 3]. It governs the propagation and interaction of all matter and force excitations, with its properties determining the phenomenology of the emergent particles. It is defined as:

$$\hat{G}_{\mathbf{\Theta\Theta}}[\psi_1^*, \psi_2] := \sum_{\alpha,\beta} c^*_{1\alpha} c_{2\beta} \left(\hat{\mathbf{\Theta}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x')\, \hat{\mathbf{\Theta}}_\beta(x')\right)$$

The Interaction Sector: $\hat{G}_{\mathbf{\Phi\Theta}}$ and $\hat{G}_{\mathbf{\Theta\Phi}}$ The *Interaction Correlators* are the off-diagonal terms that encode the direct, dynamic coupling between geometry and matter [14, 230, 7, 3].

They are defined as:

$$\hat{G}_{\mathbf{\Phi\Theta}}[\psi_1^*, \psi_2] := \sum_{\alpha,\beta} c_{1\alpha}^* c_{2\beta} \left(\hat{\mathbf{\Phi}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x')\, \hat{\mathbf{\Theta}}_\beta(x') \right)$$
$$\hat{G}_{\mathbf{\Theta\Phi}}[\psi_1^*, \psi_2] := \sum_{\alpha,\beta} c_{1\alpha}^* c_{2\beta} \left(\hat{\mathbf{\Theta}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x')\, \hat{\mathbf{\Phi}}_\beta(x') \right)$$

These operators give mathematical life to the core principles of general relativity [7]: $\hat{G}_{\mathbf{\Phi\Theta}}$ quantifies how matter sources geometric curvature, while $\hat{G}_{\mathbf{\Theta\Phi}}$ quantifies how geometry dictates the dynamics of matter. In these definitions, the terms $\hat{\mathbf{\Phi}}_\alpha(x)$ and $\hat{\mathbf{\Theta}}_\beta(x')$ represent the operator-valued field modes for the Gaiamiti and Tantrakyma fields, respectively, corresponding to the specific dialectical modes $|\alpha\rangle_x$ and $|\beta\rangle_{x'}$ of the ontological basis.

The diagonal components of the Field Correlator Matrix describe the internal dynamics of reality's two fundamental facets. The *Geometric Correlator*, $\hat{G}_{\mathbf{\Phi\Phi}}$, represents the self-relation of the Gaiamiti field and serves as the exclusive source of the emergent cosmic stage [14, 230, 3]; its expectation value gives rise to the metric and temporal tensors that define how chronogeometry propagates and correlates with itself. In parallel, the *Matter Correlator*, $\hat{G}_{\mathbf{\Theta\Theta}}$, captures the self-relational structure of the Tantrakyma field. It governs the propagation, interaction, and spectral properties—such as mass and mixing—of all emergent particles that act upon that stage.

The profound unity of the framework is encoded in the off-diagonal *Interaction Correlators*, which mathematically describe the inseparable coupling between these two sectors. These terms give rigorous, operator-level expression to the core principles of general relativity [7]: $\hat{G}_{\mathbf{\Phi\Theta}}$ quantifies how a matter excitation at one locus sources a geometric deformation at another, enacting the principle that *matter tells geometry how to curve*. Conversely, $\hat{G}_{\mathbf{\Theta\Phi}}$ describes how a geometric fluctuation influences the matter field, corresponding to the principle that *geometry tells matter how to move*. The non-vanishing of these interaction terms is a definitive statement that geometry and matter are not separate entities, but are interdependent, co-arising facets of a single, dynamically unified reality [3].

In accordance with the principle of stationary action that underpins modern physics [257], the dynamics of the IQR framework are governed by a single, fundamental quantity: the *Relational Action Functional*, $S[|\mathbf{\Psi}\rangle]$. This functional assigns a scalar value—a measure of total relational coherence—to any physically admissible quantum state, $|\mathbf{\Psi}\rangle$, allowing the preferred, physically realized state of the universe to be identified by extremizing this action. Its construction requires two key components derived from a given state: a measure of spacetime volume and a measure of the relational content within that volume.

First, to integrate over the emergent manifold, we must define a volume element. In a profound departure from theories with fixed backgrounds [3, 197], the geometry itself is state-dependent. We therefore define the *state-dependent Chronogeometric Tensor* as the expectation value of the Chronogeometric Operator in a given quantum state $|\mathbf{\Psi}\rangle$ [14]:

$$\bar{\Sigma}_{\mu\nu}^{(\mathbf{\Psi})}(x) := \langle \mathbf{\Psi} | \hat{\Sigma}_{\mu\nu}(x) | \mathbf{\Psi} \rangle.$$

The *Relational Volume Element* (Definition 6.33),

$$\sqrt{-\det \bar{\Sigma}_{\mu\nu}^{(\mathbf{\Psi})}(x)},$$

is thus dynamically determined by the quantum state of the universe itself [230]. The "substance" to be integrated over this dynamic volume is the total local self-correlation of the system, given by the trace of the Fourfold Inter-Modal Correlator's expectation value. Combining these elements yields the *Relational Action Functional* for the state $|\Psi\rangle$ (eq. (6.84)):

$$S[|\Psi\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}^{(\Psi)}_{\mu\nu}(x)} \, \mathrm{Tr}\left(\langle\Psi|\hat{\mathbf{G}}_\Lambda(x,x)|\Psi\rangle\right).$$

The integrand of this action captures the complete relational curvature at each point $x \in \mathcal{X}_q$. This curvature is composed of two distinct contributions, corresponding to the two fundamental aspects of chronogeometry:

- The curvature of *distinguishability*, derived from the emergent metric tensor, which defines spatial relationships: $\bar{g}^{(\Psi)}_{\mu\nu}(x) := \langle\Psi|\hat{g}_{\mu\nu}(x)|\Psi\rangle$ [7].
- The curvature of *quantum phase flow*, derived from the emergent temporal tensor, which defines causal and temporal relationships: $\bar{t}^{(\Psi)}_{\mu\nu}(x) := \langle\Psi|\hat{t}_{\mu\nu}(x)|\Psi\rangle$ [29].

The total state-dependent Chronogeometric Tensor is the sum of these two components:

$$\bar{\Sigma}^{(\Psi)}_{\mu\nu}(x) = \bar{g}^{(\Psi)}_{\mu\nu}(x) + \bar{t}^{(\Psi)}_{\mu\nu}(x).$$

The *Relational Action Functional* provides the theory's central dynamical law through a *variational principle* [258, 14, 259]. The physically admissible quantum states of the universe are those that extremize the action, imposing a condition of maximal coherence and minimal relational curvature:

$$\delta S[|\Psi\rangle] = 0.$$

The set of all states $|\Psi\rangle_{\text{vac}}$ that satisfy this principle constitutes the *Vacuum Manifold* (Definition 6.61) [260, 261]. Within this manifold lies the single distinguished state that describes our realized cosmos: the *Quantum Holo-State*, $|\mathring{\Psi}\rangle$ [3, 197].

When the general, state-dependent definitions are evaluated for this universal vacuum state, they reduce to their canonical forms. The *Chronogeometric Tensor* becomes the canonical vacuum geometry furnishing the background of our universe:

$$\bar{\Sigma}_{\mu\nu}(x) := \langle\mathring{\Psi}|\hat{\Sigma}_{\mu\nu}(x)|\mathring{\Psi}\rangle \quad (\text{cf. } \textit{Definition } 5.26)\ [7,\ 8,\ 3].$$

The action functional in turn evaluates to its realized vacuum value:

$$S[|\mathring{\Psi}\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}(x)} \, \mathrm{Tr}\Big(\langle\mathring{\Psi}|\hat{\mathbf{G}}_\Lambda(x,x)|\mathring{\Psi}\rangle\Big)$$

[262, 263].

This canonical geometry, determined entirely by the Quantum Holo-State, provides the stable background against which all local fluctuations, particles, and interactions are defined [264, 146]. The *Relational Action Functional* (Definition 6.38) thus serves as the *master functional* governing the total dynamics of the IQR framework [14, 258].

To resolve its internal structure, we may decompose the total action into sectors corresponding to the block decomposition of the *Field Correlator Matrix* $\hat{\mathbf{G}}_\Lambda$ [82, 243]:

$$S[|\Psi\rangle] = S_{\Phi\Phi} + S_{\Theta\Theta} + S_{\Phi\Theta} + S_{\Theta\Phi}.$$

This separation isolates the distinct variational principles for:

- **Geometry** ($S_{\Phi\Phi}$): the pure Gaiamiti sector [7],
- **Matter** ($S_{\Theta\Theta}$): the pure Tantrakyma sector [82],
- **Interaction** ($S_{\Phi\Theta}, S_{\Theta\Phi}$): the bidirectional coupling between geometry and matter [146, 264].

Such a decomposition makes explicit how the master variational principle governs not only the emergent background structure but also the mutual dynamical influence of the universe's two fundamental facets.

The *Gaiamitiic Action*, S_Φ, is defined by projecting onto the geometric sector. It is the functional whose variation governs the emergence of pure chronogeometry—the metric and causal structure of spacetime [7, 146, 264]:

$$S_\Phi[|\Psi\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}(x)} \, \mathrm{Tr}\left(\langle\Psi|\hat{G}_{\Phi\Phi}(x,x)|\Psi\rangle\right).$$

In parallel, the *Tantrakyma Action*, S_Θ, is defined from the matter sector. Its variation governs the dynamics of all material content, including mass generation and internal symmetries [82, 243, 97, 99]:

$$S_\Theta[|\Psi\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}(x)} \, \mathrm{Tr}\left(\langle\Psi|\hat{G}_{\Theta\Theta}(x,x)|\Psi\rangle\right).$$

Finally, the crucial *Interaction Action*, $S_{\Phi\Theta}$, is derived from the off-diagonal correlators. This term encodes the quantum analog of gravitational coupling, describing the inseparable dialogue where geometry influences matter and vice versa [6, 146, 264]:

$$S_{\Phi\Theta}[|\Psi\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}(x)} \, \mathrm{Tr}\left(\langle\Psi|\left[\hat{G}_{\Phi\Theta}(x,x) + \hat{G}_{\Theta\Phi}(x,x)\right]|\Psi\rangle\right).$$

This decomposition makes it clear that the total Relational Action Functional, $S[|\Psi\rangle]$, serves as a *unified variational umbrella* [258, 14]. A single principle of stationary action, applied to this total functional, simultaneously and self-consistently determines the dynamics of spacetime, the behavior of matter, and the fundamental laws of their interaction.

Applying this variational principle yields the theory's central dynamical law for the emergent manifold—a profound generalization of the Einstein Field Equations [6, 146, 7] (Section 11.5.4), the field equations that govern the evolution of the emergent chronogeometric manifold. These equations relate the curvature of the unified geometry to the total stress-energy content of the universe. The semi-classical field equations for the expectation-level chronogeometric tensor $\bar{\Sigma}_{\mu\nu}(x)$ are given by the *Chronogeometric Einstein Equations*:

$$\bar{G}_{\mu\nu}[\bar{\Sigma}] + \Lambda\bar{\Sigma}_{\mu\nu} = \kappa\bar{T}^{\mu\nu}_{\text{total}}(x),$$

where:

- $\bar{G}_{\mu\nu}[\bar{\Sigma}]$ is the *Einstein tensor of the unified geometry.*
- Λ is the *emergent cosmological constant* (Definition 17.2).
- κ is the *relational gravitational coupling constant* (Section 11.5.3).
- $\bar{T}^{\mu\nu}_{\text{total}}(x)$ is the *total expectation-valued stress–energy tensor* (Section 9.18.12), representing the complete energy, momentum, and stress content of both the Gaiamiti (geometric) and Tantrakyma (matter) fields [244, 13].

Equation (11.191) is the central dynamical law of emergent spacetime in this framework. While it bears a formal resemblance to the classical Einstein Field Equations [6, 7], its physical content is significantly richer:

- *The Geometric Side (LHS):* The Einstein tensor $\bar{G}_{\mu\nu}[\bar{\Sigma}]$ is not derived from a simple metric but from the unified tensor $\bar{\Sigma}_{\mu\nu} = \bar{g}_{\mu\nu} + \bar{t}_{\mu\nu}$. It therefore describes curvature in both the spatial distinguishability ($\bar{g}_{\mu\nu}$) and the **quantum phase flow** ($\bar{t}_{\mu\nu}$) of the manifold [3, 265]. The geometry adapts not only to the distribution of energy but also to the distribution of quantum coherence.
- *The Source Side (RHS):* The source of this curvature, $\bar{T}^{\mu\nu}_{\text{total}}$, is the expectation value of the total quantum stress-energy operator (Section 9.18.12). It includes the energy of matter and radiation (from the Tantrakyma field) as well as the energy of the geometric field itself (from the Gaiamiti field). This establishes a self-consistent feedback loop where the energy of the geometry contributes to its own curvature [244, 13].

In essence, these equations state that the total chronogeometric curvature of the emergent universe is proportional to the total quantum stress-energy content within it. While these field equations describe the emergent dynamics, a deeper insight into the system's total energy and its fundamental quantum nature is provided by the *Relational Hamiltonian*, $\hat{H}$ [258, 14].

In a background-independent framework [3, 265], the Hamiltonian represents the total relational energy of a given quantum state. Its physical meaning is defined implicitly: the expectation value of the Hamiltonian in a state $|\mathbf{\Psi}\rangle$ *is* the value of the Relational Action Functional for that state [258, 14] (eq. (6.107)):

$$\langle \mathbf{\Psi} | \hat{H} | \mathbf{\Psi} \rangle := S[|\mathbf{\Psi}\rangle].$$

This principle is given an explicit mathematical form by constructing a state-dependent operator, $\hat{H}[|\mathbf{\Psi}\rangle]$, as the integral of the local correlator's trace over the emergent manifold (eq. (6.108)):

$$\hat{H}[|\mathbf{\Psi}\rangle] := \int_{\mathcal{X}_q} d^d x \, \sqrt{-\det \bar{\Sigma}^{(\mathbf{\Psi})}_{\mu\nu}(x)} \, \text{Tr}_{\text{op}} \left(\hat{\mathbf{G}}_\Lambda(x,x) \right),$$

where Tr_{op} is the partial trace over the internal field and dialectic indices. The state-dependence of this Hamiltonian is a crucial and necessary feature of the theory's self-consistency [3, 265]. Arising from the volume element $\sqrt{-\det \bar{\Sigma}^{(\mathbf{\Psi})}}$, it signifies that the very geometry used to measure the universe's total energy is itself determined by the state being measured.

Just as the action was decomposed, the total Hamiltonian inherits its structure from the Field Correlator Matrix [266, 8, 3]. It thus admits a canonical decomposition into geometric (Gaiamitiic), matter (Tantrakyma), and Interaction components (eq. (6.109)):

$$\hat{H}[|\mathbf{\Psi}\rangle] = \hat{H}_{\Phi}[|\mathbf{\Psi}\rangle] + \hat{H}_{\Theta}[|\mathbf{\Psi}\rangle] + \hat{H}_{\Phi\Theta}[|\mathbf{\Psi}\rangle],$$

where each component is defined by integrating the trace of the corresponding correlator block:

$$\begin{aligned}
\hat{H}_{\Phi}[|\mathbf{\Psi}\rangle] &:= \int_{\mathcal{X}_q} d^d x \sqrt{-\det \bar{\Sigma}^{(\mathbf{\Psi})}}\, \mathrm{Tr}_{\mathrm{op}} \left(\hat{G}_{\mathbf{\Phi\Phi}}(x,x) \right), \\
\hat{H}_{\Theta}[|\mathbf{\Psi}\rangle] &:= \int_{\mathcal{X}_q} d^d x \sqrt{-\det \bar{\Sigma}^{(\mathbf{\Psi})}}\, \mathrm{Tr}_{\mathrm{op}} \left(\hat{G}_{\mathbf{\Theta\Theta}}(x,x) \right), \\
\hat{H}_{\Phi\Theta}[|\mathbf{\Psi}\rangle] &:= \int_{\mathcal{X}_q} d^d x \sqrt{-\det \bar{\Sigma}^{(\mathbf{\Psi})}}\, \mathrm{Tr}_{\mathrm{op}} \left(\hat{G}_{\mathbf{\Phi\Theta}}(x,x) + \hat{G}_{\mathbf{\Theta\Phi}}(x,x) \right).
\end{aligned}$$

The physical ground states of the universe are the eigenstates of the Hamiltonian with the lowest energy eigenvalue, E_0 [258, 14]. This ground state eigenspace, $\mathcal{V}_0 = \ker(\hat{H} - E_0 \mathbb{I}_{\mathrm{em}})$, is precisely the set of states that minimize the action, thereby defining the *Vacuum Manifold*, $\mathcal{M}_{\mathrm{vac}}$ (Definition 6.61).

A central consequence of the Interdependent Quantum Reality (IQR) framework is that time is not a fundamental background parameter but an emergent, relational construct [197, 3]. Therefore, the universe's dynamics cannot be described by a standard Schrödinger equation, which presupposes an external time parameter for evolution. Instead, the fundamental law must be a *constraint* imposed on the total quantum state of the cosmos. This approach elevates the logic of the Wheeler–DeWitt equation [156, 8, 3] to a fully operator-theoretic context, yielding a single, timeless law known as the *Universal Quantum Constraint*.

The operator that governs this constraint is the *Total Relational Hamiltonian*, $\hat{H}_{\mathrm{univ}}$ [266, 8, 3]. Formally derived from the total action functional (Definition 9.357) via a Legendre transform, this Hamiltonian encapsulates the complete dynamics of the system. It is the sum of the geometric (Gaiamiti), matter (Tantrakyma), and interaction sectors (Definition 13.167):

$$\hat{H}_{\mathrm{univ}} := \hat{H}_{\Phi} + \hat{H}_{\Theta} + \hat{H}_{\mathrm{int}}.$$

The fundamental law of the IQR universe is the **Universal Quantum Constraint** [156, 3], expressed as a stationary, zero-eigenvalue solution for the **Quantum Holo-State**, $|\mathring{\mathbf{\Psi}}\rangle$ (Theorem 13.168):

$$\hat{H}_{\mathrm{univ}} |\mathring{\mathbf{\Psi}}\rangle = 0.$$

The operator in this expression, the **Total Relational Hamiltonian** $\hat{H}_{\mathrm{univ}}$, is a fundamentally unified object derived from the Total Relational Action (Definition 9.357) that intrinsically includes the dynamics of the geometric (Gaiamiti), matter (Tantrakyma), and interaction sectors [266, 8, 3]. This single constraint thus represents a unified quantum law for the entire coupled system of matter and geometry.

This equation asserts that the universe is a fully self-contained system whose total relational energy vanishes [197, 3]. It is not an equation for geometry *with* matter sources,

but a constraint on the one timeless, entangled state from which both are derived. As such, the Universal Quantum Constraint represents the background-independent generalization of the Schrödinger equation, where any notion of time must emerge from within the relational structure of the state itself [156, 8, 3].

How can a universe governed by this timeless constraint give rise to the familiar experience of evolution? The answer lies in partitioning the total system [3, 197]. While the Quantum Holo-State of the entire cosmos is stationary, an observer *within* the universe is a subsystem. Such an observer can describe the evolution of another subsystem (the "system of interest") relative to the rest of the universe, which acts as a clock and reference frame. This gives rise to an **effective, emergent dynamics** governed by a time-dependent Schrödinger equation [215, 8, 3].

The evolution of any such subsystem is governed by this emergent dynamical law (eq. (17.47)):

$$i\hbar\frac{d}{dt}|\mathring{\boldsymbol{\Psi}}(t)\rangle = \hat{H}_{\text{rel}}(t)|\mathring{\boldsymbol{\Psi}}(t)\rangle$$

The operator that drives this effective evolution is the **Total Relational Hamiltonian**, $\hat{H}_{\text{rel}}$, which contains the entirety of cosmic phenomenology:

$$\hat{H}_{\text{rel}} = \underbrace{\hat{H}_{\text{geometry}}[\hat{\Sigma}_{\mu\nu}]}_{\text{Dark Energy \& Dark Matter}} + \underbrace{\hat{H}_{\text{matter}}[\hat{\phi}, \hat{\psi}, \dots]}_{\text{Standard Model}}.$$

This single effective Hamiltonian is composed of two sectors:

1. **The Geometric Hamiltonian ($\hat{H}_{\text{geometry}}$):** This operator governs the dynamics of the **Gaiamiti field** ($\hat{\Phi}$), whose quanta are the **Apeirons** [267]. Its ground state eigenvalue is the Cosmological Constant (Λ), the physical origin of **Dark Energy**, while its large-scale coherent excitations are the physical manifestation of **Dark Matter** (Section 13.1).

2. **The Matter Hamiltonian ($\hat{H}_{\text{matter}}$):** This operator governs the dynamics of the **Tantrakyma field** ($\hat{\Theta}$), whose quanta are the **Kymons**. Its excitations and their interactions give rise to the entire particle zoo of the **Standard Model** [14] (Chapter 12).

Thus, the familiar phenomena of our evolving universe are understood as different facets of a single, unified, but fundamentally timeless relational structure [3, 197].

While the emergent Schrödinger equation governs the dynamics of subsystems, the **Total Relational Hamiltonian**, $\hat{H}_{\text{rel}}$, that drives this evolution is not itself a fundamental entity [3, 215]. It is a global operator that arises from a deeper, more localized layer of reality's relational structure. The most basic building block of all dynamics in the IQR framework is the **Fourfold Inter-Modal Correlator**, $\hat{G}_\Lambda(x, x')$. This is a bi-local (two-point) operator-valued function whose essential role is to define the quantum-relational link—the entanglement and coherence—between any two Primordial Quantum Singularities at points x and x' [8, 3].

The global operator that we identify as the Total Relational Hamiltonian is constructed from this fundamental correlator. The process involves taking the local part of the correlator where the two points coincide ($\hat{G}_\Lambda(x, x)$), tracing over its internal indices to yield a local relational energy density, and then integrating this density over the entire emergent manifold,

$\mathcal{X}_q$. The Hamiltonian is thus the macroscopic, integrated sum of all microscopic, relational interactions across the cosmos.

The emergent Schrödinger equation (eq. (17.47)) therefore describes how the **Quantum Holo-State**, when viewed from the perspective of an internal subsystem, appears to evolve under the influence of this total, integrated interaction energy [215]. The solution, $|\mathring{\mathbf{\Psi}}(t)\rangle$, is a single quantum state whose different aspects we perceive as the familiar world of particles, the enigmatic halos of dark matter, and the accelerating expansion driven by dark energy (Section 13.1). In this light, the majestic evolution of the universe is understood to be the global manifestation of the profound relational dynamics encoded within the Fourfold Inter-Modal Correlator.

The Universal Quantum Constraint defines a perfectly self-contained or *Ātmapoiesis Universe* [197] (Section 17.2.1). While the term "Ātmapoiesis Universe" originates in philosophical discourse regarding self-contained being, in the IQR framework it is given a precise mathematical definition as the quantum state satisfying the Universal Quantum Constraint:

$$\hat{H}_{\text{univ}}|\mathring{\mathbf{\Psi}}\rangle = 0.$$

This foundational state represents a universe of perfect internal balance, requiring no external reference.

However, the foundational *Axiom of Duality* asserts that to define any entity is to simultaneously define its complement; nothing can exist in isolation (Section 1.2.6). Applied to the cosmos itself, this principle leads to a profound conclusion: a universe defined by self-containment can only be one half of a greater, inseparable whole. This implies the existence of two complementary ontological poles.

The necessary dual to the Ātmapoiesis Universe is the *Parapoiesis Universe* (eq. (17.50)), a state whose existence is defined by its dependence on a transcendent source, $\mathfrak{B}_{\vec{r}}$, transforming the mathematics of self-containment into a formalism of perpetual dependence:

$$\hat{H}_{\text{univ}}|\mathring{\mathbf{\Psi}}\rangle = \mathfrak{B}_{\vec{r}}.$$

The IQR framework dictates that these two possibilities are not mutually exclusive but must coexist in a quantum superposition [197, 3]. The full state of reality, the *Holocosmos state* $|\mathbf{\Omega}\rangle$, is therefore an entangled state of both the atmapoiesis and parapoiesis branches (Definition 17.20 and eq. (17.52)):

$$|\mathbf{\Omega}\rangle = \alpha\,|\mathring{\mathbf{\Psi}}_{\bar{\text{A}}\text{tmapoiesis}}\rangle \otimes |\bar{\text{A}}\text{tmapoiesis}\rangle + \beta\,|\mathring{\mathbf{\Psi}}_{\text{Parapoiesis}}\rangle \otimes |\text{Parapoiesis}\rangle,$$

where $\alpha, \beta \in \mathbb{C}$ are complex amplitudes, and $|\mathring{\mathbf{\Psi}}_{\bar{\text{A}}\text{tmapoiesis}}\rangle$ and $|\mathring{\mathbf{\Psi}}_{\text{Parapoiesis}}\rangle$ are the respective pure states of the universe in each branch [188].

This total state of reality is governed by a higher-order constraint that unifies the two branches into a single, self-consistent system, the *Holocosmos Constraint Equation* (eq. (17.54)):

$$\left(\hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}} - \mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}}\right)|\mathbf{\Omega}\rangle = 0,$$

where the operators are defined as:

- $\hat{H}_{\text{univ}}$ is the Total Relational Hamiltonian, acting on the universe's state space [156].
- $\hat{\mathfrak{B}}$ is the Source Operator, which distinguishes between the two branches with the eigenvalue structure:

$$\hat{\mathfrak{B}}|\bar{\text{A}}\text{tmapoiesis}\rangle = 0$$
$$\hat{\mathfrak{B}}|\text{Parapoiesis}\rangle = \mathfrak{B}_{\vec{r}}|\text{Parapoiesis}\rangle$$

- $\mathbb{I}_{\text{univ}}$ and $\mathbb{I}_{\mathfrak{B}}$ are the identity operators on their respective spaces.

The foundational and irreducible principle of the treatise is the *Axiom of Duality* [268]. It asserts that to define any entity is to simultaneously define its complement; nothing can be known or can exist in isolation [169]. This principle manifests at every level of reality, from the most fundamental constituents of the cosmos to the very nature of the cosmos itself [197].

The ultimate expression of the Axiom of Duality is found in the nature of existence, representing the two inseparable ontological poles of reality (Section 17.3.1):

1. The *Ātmapoiesis Universe*, corresponding to the $|\overset{\circ}{\mathbf{0}}\rangle$ state. This is the state of perfect self-containment, a universe whose total relational energy vanishes to nullity ($\hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}\rangle = 0$) and whose existence is defined by a perfect internal balance [156].

2. The *Parapoiesis Universe*, corresponding to the $|\overset{\circ}{\mathbf{1}}\rangle$ state. This is the state of being-sourced, of existence defined by its dependence on a transcendent source ($\hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}\rangle = \mathfrak{B}_{\vec{r}}$) and defined by its external relation [188].

This profound symmetry, scaling from the fundamental basis states to the entire cosmos, is given its most potent mathematical expression as a single, inseparable, interdependent pair:

$$|\overset{\circ}{\mathbf{0}}\rangle \leftrightarrow |\overset{\circ}{\mathbf{1}}\rangle$$
$$\hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}_{\bar{\text{A}}\text{tmapoiesis}}\rangle = 0 \leftrightarrow \hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}_{\text{Parapoiesis}}\rangle = \mathfrak{B}_{\vec{r}}$$

($\bar{\text{A}}$tmapoiesis Reality $\leftrightarrow$ Parapoiesis Reality)

The architecture of the Interdependent Quantum Reality framework culminates in a single, unifying mathematical object: the **Algebraic Action of the Timeless Reality of the Holocosmos** (Section 17.3.2). This functional provides the foundation for quantum systems governed by algebraic constraints, transcending conventional field-theoretic approaches that rely on temporal integration [3].

The action is defined not as an integral over time, but as the expectation value of the **Holocosmos Constraint Operator** within the total state of reality, $|\mathbf{\Omega}\rangle$ [3, 197]:

$$\overset{\circ}{\mathbf{\Lambda}}[\mathbf{\Omega}] = \left\langle \mathbf{\Omega} \middle| \left(\hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}} - \mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}} \right) \middle| \mathbf{\Omega} \right\rangle .$$

This formulation reveals the deep connection between extremal principles and constraint enforcement [269]. The stationary action principle ($\delta\overset{\circ}{\mathbf{\Lambda}} = 0$) is no longer a search for a

"path of least action" through time, but a principle that selects for the state which satisfies the fundamental constraint. Variation with respect to the bra state $\langle\mathbf{\Omega}|$ directly yields the **Holocosmos Constraint Equation** (eq. (17.65)):

$$\left(\hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}} - \mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}}\right)|\mathbf{\Omega}\rangle = 0 \quad \Longleftrightarrow \quad \left(\hat{H}_{\text{univ}} \otimes \mathbb{I}_{\mathfrak{B}}\right)|\mathbf{\Omega}\rangle = \left(\mathbb{I}_{\text{univ}} \otimes \hat{\mathfrak{B}}\right)|\mathbf{\Omega}\rangle.$$

This purely algebraic action is the mathematical foundation that encodes and unifies the complete structural logic of the IQR framework [14]. This single expression simultaneously captures the theory's most fundamental principles (Section 17.3.2):

- **The Axiom of Duality:** The action emerges from operators $\hat{H}_{\text{univ}}$ and $\hat{\mathfrak{B}}$ operating on distinct, complementary subspaces. This embeds the fundamental duality of reality directly into the mathematical substrate of the theory [268, 169].
- **The Entangled State:** The action functions as a generator over the entangled Metaverse state $|\mathbf{\Omega}\rangle$ [188]. Consequently, any state that extremizes the action must necessarily manifest the entangled structure that correlates the universe with its ontological foundation.
- **The Governing Law:** The constraint equation emerges as the natural consequence of extremizing the action, rather than being imposed as an external postulate [269]. The dynamical law is revealed as the necessary condition for achieving a stationary, self-consistent configuration in the space of all possible states.

The grand architecture of this framework finds its ultimate expression in the *Axiom of Duality* [268, 197]—a principle asserting that to define any entity is to simultaneously define its complement; nothing can exist in isolation. This axiom manifests at every scale of reality, from the foundational quantum states to the very nature of the cosmos itself, dictating that existence must be understood as an irreducible duality of two fundamental ontological modes.

The first mode is the *Ātmapoiesis Universe*—a state of perfect self-containment whose existence emerges from complete internal balance, where the total relational energy vanishes to nullity ($\hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}\rangle = 0$) [197, 3]. This is a cosmos that requires no external foundation, defining itself through its own internal coherence and symmetry. Its necessary counterpart is the *Parapoiesis Universe*—a state of radical dependence whose very being is constituted by its relationship to a transcendent source ($\hat{H}_{\text{univ}}|\overset{\circ}{\mathbf{\Psi}}\rangle = \mathfrak{B}_{\vec{r}}$) [268]. This is a cosmos that exists not through self-sufficiency but through continuous creative relationship with that which exceeds and grounds it.

These two ontological modes are not separate realities but constitute a single, unified system governed by the *Holocosmos Constraint Equation* (eq. (17.54)). This equation emerges from the deeper *Holocosmos Constraint Operator* (Section 17.3), which mathematically encodes the necessary entanglement between self-contained and source-dependent modes of being [188]. Yet, this mathematical formalism is no mere construct; its intrinsically relational nature is the direct consequence of a more primordial truth. The *Axiom of Duality* [268], the paired existence of Ātmapoiesis and Parapoiesis realities, and the very equations that unify them are themselves expressions of the fundamental **Law of Dependent Origination** [17]—the principle that all phenomena arise only through their interdependent relationships. This

universal law provides the ultimate ontological foundation that transcends even the duality it generates [169].

It reveals that the apparent opposition between self-containment and dependence dissolves into a deeper recognition: all existence, whether seemingly autonomous or manifestly parapoiesis, participates in the same fundamental pattern of relational arising. Reality, in its totality, is thus revealed as a seamless web of interdependent emergence—neither purely self-created nor externally imposed, but arising through the creative tension of relationality itself. In this light, the IQR framework becomes more than a unification of quantum mechanics and gravity [14, 8, 3]; it becomes a mathematical expression of the most fundamental insight about the nature of existence: that being itself is relational, and that the deepest truth of reality lies not in any single mode of experience but in the dynamic, creative interdependence that gives rise to all possible worlds.

1.1.1 The Relationship Between IQR and Existing Frameworks

This approach consciously builds upon several influential lines of research while proposing a significant departure from their foundational assumptions:

Algebraic Quantum Field Theory (AQFT): Like AQFT, the IQR utilizes the formal power of operator algebras and the Gelfand-Naimark-Segal (GNS) construction to derive a Hilbert space representation from a state defined over a global algebra (Definition 1.34) [230, 241]. However, where AQFT typically presupposes a fixed background spacetime on which nets of local algebras are defined, our framework inverts this ontological hierarchy. The algebra of PQSs on the foundational $\hat{\mathbf{\Omega}}$–Continuum (Definition 4.617) is primary, and it is from this structure that the emergent quantum configuration space $\mathcal{X}_q$ (Proposition 4.625) and the subsequent chronogeometric manifold $\mathcal{M}_{\text{em}}^{(\mathring{\mathbf{\Psi}})}$ (Definition 5.113) are generated.

Tensor Networks and AdS/CFT: The revolutionary idea that geometry is woven from the threads of quantum entanglement, explored fruitfully in tensor network models and the AdS/CFT correspondence [270, 2, 271, 1], serves as a powerful signpost for our journey. The IQR advances this concept by elevating entanglement from a descriptive tool to a primary ontological constituent. Rather than reconstructing a pre-supposed geometry from a boundary theory, we posit that the relational entanglement encoded by the Quantum Holo-State and manifested via operator correlators like $\hat{\mathbf{G}}_\Lambda$ (Definition 4.9) *is* the geometry. We are thus liberated from the need for discrete lattices or prescribed background spacetimes, aspiring to a theory that is continuous, dynamic, and universal.

Relational Quantum Mechanics and Background Independence: This vision is fundamentally relational, in the tradition of Relational Quantum Mechanics (RQM) and the quest for background independence that animates Loop Quantum Gravity and Causal Set Theory [3, 265, 272]. Yet, where these approaches champion the principle of relationalism, our framework gives it flesh and bone through a concrete operator geometry. The introduction of the operator-valued metric $\hat{g}_{\mu\nu}(x)$ (Definition 5.1) and its tangible, expectation-level coun-

terpart $\bar{g}_{\mu\nu}(x)$ (Definition 5.10) forges an unbreakable, derivable link between philosophical principle and predictive physical theory.

Noncommutative Geometry: Our departure from classical differential geometry aligns with the spirit of Connes' Noncommutative Geometry (NCG), which defines space through the spectrum of operators rather than the assembly of points [4]. The IQR shares this operator-algebraic foundation but places the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ in a central, generative role that is absent in NCG. In our formalism, $|\mathring{\mathbf{\Psi}}\rangle$ is the fundamental entity from which all physical and geometric quantities descend, ensuring the framework is intrinsically quantum from its inception.

Topos Theory: Topos-theoretic approaches to quantum foundations offer sophisticated mathematical frameworks that move beyond Hilbert-space-centric formulations, using toposes and sheaves to handle contextuality and logical structure without necessarily assuming a background spacetime [27, 28, 29]. These frameworks excel at reformulating quantum *logic* and the interpretation of states and observables from a categorical or neo-realist perspective, often emphasizing the epistemic or logical structure of quantum theory.

However, while topos theory can beautifully describe the contextual logic of a quantum world, it typically does not aim to derive a full dynamical operator geometry with emergent metric structure and causal relations in the same direct way as the IQR. The IQR approach advances beyond this by presenting the $\hat{\mathbf{\Omega}}$–Continuum as *ontologically physical*, composed of operator-valued singularities rather than abstract logical categories. Our goal is not to perfect the logic of what is, but to unveil the ontology of how it came to be—where emergent geometry is not an abstraction of logic but is constituted by the relational, operator-theoretic entanglement encoded in $|\mathring{\mathbf{\Psi}}\rangle$. The $\hat{\mathbf{\Omega}}$–Continuum is not an abstract category; it is the physical, singular seed of all that is.

Vision and Guiding Principles

The Interdependent Quantum Reality (IQR) framework presents a profound reconceptualization of physical reality: the universe is not a collection of objects moving through spacetime, but a single, indivisible quantum system from which space, time, matter, and forces emerge as different aspects of an underlying relational structure. In this vision, geometry is not the stage upon which physics unfolds—it is the relational fabric itself, woven from quantum entanglement. The laws of physics are not external constraints but necessary consequences of internal quantum coherence.

This revolutionary perspective rests upon four foundational principles that guide the mathematical development:

The Four Guiding Principles

1. **Dependent Origination:** The Law of Dependent Origination is the fundamental principle that governs the generation and interdependence of all phenomena (Sections 1.1.2, 17.1, 17.1.7 and 17.3.2).

2. **The Fourfold Dialectic Algebra of Symmetry:** All *dependently originated* phenomena are completely described by the self-similar, fourfold dialectical algebra([17, 35, 273, 15, 16, 274, 46]) that consists of: Thesis (Symmetry), Antithesis (Antisymmetry (Section 2.1)), Synthesis (Parasymmetry (Definitions 2.85 and 2.94)), and Holothesis (Holosymmetry (Section 2.3)).

3. **Reality is Emergent:** The continuum on which *dependently originated reality* is defined is the $\hat{\mathbf{\Omega}}$-Continuum (Section 4.18) of fibred *ultra-sub-Planckian* Primordial Quantum Singularities (Definition 1.25). Each primordial quantum singularity is endowed with the Fourfold Dialectic Algebra of Symmetry. All geometric and temporal properties—including chronogeometric spacetime and causality—emerge from this relational substrate as the expectation values of fundamental, operator-valued chronogeometric operators (Section 5.2.6), evaluated in the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ over this continuum of singularities.

4. **The Generative Quantum Holo-State:** The Quantum Holo-State ($|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.34)) is a single, non-factorizable quantum state that both encodes and generates the indivisible reality in which it resides. This is the singular wellspring from which all physical structure emerges. It is this state that gives rise to the *Fourfold Inter-Modal Correlator Operator* (Definition 4.9), the very engine of relational dynamics. From its coherent structure, the inner product and the geometry of the *emergent Hilbert spaces* (Section 4.1) are born. Furthermore, this universal state projects itself into the two fundamental facets of existence: the *Gaiamiti Field*, whose quanta, the *apeirons*, are the progenitors of the graviton and the fabric of chronogeometry itself; and the *Tantrakyma Field*, whose quanta, the *kymons*, blossom into the complete edifice of the Standard Model: its rich and varied spectrum of particles, and the fundamental interactions that govern their existence.

1.1.2 The Law of Dependent Origination

At the very heart of both ancient Buddhist philosophy and the relational fabric of our emergent cosmos, lies the **Law of Dependent Origination**, or *Pratītyasamutpāda* [275, 276]. It is a principle of dynamic continuity of interdependence and entanglement, a declaration that no phenomena, from the fleeting thought of a sentient being to the grandest cosmic structure, possesses any intrinsic, independent existence. Instead, all phenomena arise in a seamless, unbroken interwoven cyclic web of mutual causation, conditioning, and effects. The principle is captured with sublime economy in the ancient formula:

> *When this is, that is.*
> *From the arising of this, that arises.*
> *When this is not, that is not.*
> *From the cessation of this, that ceases.*

On the surface this may seem like a statement of linear cause and effect. However, this is far from the truth, for it describes a universe where reality is not a collection of isolated

objects but a dynamic, living network of relationships. The statement of the existence of any single entity is parapoiesis upon the existence of all others; its identity is woven from the threads of its conditions, and it, in turn, becomes a condition for the arising of what is yet to be.

The Architecture of Experiential Existence

To illustrate the workings of this law, particularly in the realm of sentient experience, the teaching is often presented as a great causal chain of twelve interdependent links, or *nidānas* [275, 277]. This sequence is not a simple temporal progression but a cyclical, self-perpetuating structure that describes the very mechanism of entanglement in the cycle of existence, or *samsara* [278]. The twelve-link chain of dependent origination begins with **(1)** *ignorance (avidyā)*—a fundamental misapprehension of reality itself [279]. This ignorance manifests as the deep-seated delusion that phenomena possess an independent, enduring self-nature, a misunderstanding that serves as the root condition for all subsequent suffering.

Conditioned by this basic ignorance, **(2)** *formations (saṃskāra)* arise as volitional impulses and karmic imprints. These formations represent the relational patterns of intention that shape the trajectory of future experience, carrying the momentum of past actions into present and future moments. From these accumulated formations emerges **(3)** *consciousness (vijñāna)*, the basic stream of awareness that provides continuity across moments and lifetimes, linking discrete experiences into a coherent flow of subjective experience [275]. This consciousness, in turn, conditions the arising of **(4)** *name and form (nāmarūpa)*—the psycho-physical organism that constitutes the living being [277]. Here, "name" encompasses the mental phenomena of feeling, perception, and intention, while "form" refers to the physical body and material world. Together, they create the inseparable duality of mind and matter that characterizes embodied existence [279].

The psycho-physical organism naturally develops **(5)** *the six sense bases (Ṣaḍāyatana)*—the five physical senses along with the mind itself as the sixth faculty of perception [275]. These sense bases serve as the interface between consciousness and its environment, establishing the conditions for experiential encounter with the world. When a sense faculty meets its corresponding object in the presence of consciousness, **(6)** *contact (sparśa)* occurs. This represents the raw moment of sensory input, the immediate meeting of perceiver and perceived that forms the foundation of all experiential content [277]. From each instance of contact arises **(7)** *feeling (vedanā)*—the immediate, pre-conceptual experience of pleasantness, unpleasantness, or neutrality that colors every moment of awareness [275].

These feeling-tones, however subtle, condition the arising of **(8)** *craving (tṛṣṇā)* [279]. Pleasant feelings generate the desire for repetition and continuation, while unpleasant feelings fuel the impulse toward escape and avoidance. This craving, when it becomes habituated and intensified, transforms into **(9)** *grasping (upādāna)*—a deep-seated clinging to existence, sensory experience, views, and the notion of selfhood itself. The accumulated energy of grasping fuels the process of **(10)** *becoming (bhava)*, creating the karmic momentum that propels the stream of consciousness toward future manifestation. This momentum conditions **(11)** *birth (jāti)*—the arising of a new psycho-physical form, complete with its inherited patterns and predispositions [278].

Finally, with birth comes the inevitable reality of **(12)** *aging and death (jarā-maraṇa)*—the

entire cycle of suffering including decay, disease, separation, and dissolution [277]. Rather than leading to liberation, these experiences of impermanence typically reinforce the original ignorance, deepening the delusion of selfhood and perpetuating the cycle indefinitely. Thus the wheel of dependent origination completes one revolution while simultaneously beginning another, creating an unbroken chain of conditioned existence that continues until the root ignorance is finally recognized and abandoned [279].

Philosophical Implications: The Middle Way

The Law of Dependent Origination is the foundation of what is known as the **Middle Way**. It steers a careful course between the two philosophical extremes of **eternalism** (the belief in a permanent, unchanging self or substance) and **annihilationism** (the belief that things cease to exist entirely). By revealing all phenomena as dependently arisen, it shows that nothing is permanent, yet the causal web ensures a continuity of process.

For the great philosopher *Nāgārjuna*, understanding Dependent Origination was synonymous with understanding reality itself. He famously equated it with the principle of **emptiness** (Śūnyatā): "It is dependent origination that we call emptiness" ([278, 35, 279]). Because all phenomena arise in dependence on conditions, they are *empty* of any intrinsic, self-sufficient nature. Emptiness, in this context, is not a void, but the very mark of relational existence. It is the ultimate expression of a universe that is not a collection of things, but a single, indivisible, and interdependent whole. The twelve-link chain of dependent origination reveals the interconnected nature of existence, but one relationship stands as particularly crucial to Buddhist understanding of reality: the reciprocal interdependence between *consciousness (viññāṇa)* and *name-and-form (nāmarūpa)*.

In Buddhist terminology, "name" encompasses the mental dimensions of experience—feeling, perception, and intention—namely, the cognitive processes that *name, label, categorize, and construct* our sensory encounters. "Form" by contrast, refers to the physical realm: our bodily existence and the material world around us—*to which we also assign* "names"—and the cognitive processes that *name, label, categorize, and construct* our sensory encounters. Together, these components *constitute* what we recognize as the complete psychophysical being.

Name and Form: A Duality of Reality The *Mahānidāna Sutta (The Great Discourse on Causation)* [275, 276] presents the Buddha's most penetrating analysis of this interdependence. Speaking to his disciple Ānanda, the Buddha reveals that consciousness and the experienced world do not exist as separate entities in a simple cause-and-effect relationship. Rather, they emerge together in an indivisible process of mutual arising. As the Buddha teaches [275, 276]:

> From name-and-form as a requisite condition
> comes consciousness.
> From consciousness as a requisite condition
> comes name-and-form...
>
> — Dīgha Nikāya 15

Buddha illuminates this perfect interdependence through a striking metaphor: consciousness and name-and-form resemble two bundles of reeds leaning against each other for support.

Remove either bundle, and both immediately collapse [275]. This teaching fundamentally contrasts with the Western philosophical tradition, which typically assumes a conscious subject existing independently of an objective world it observes [179, 182]. Buddhist insight reveals instead that the *"knower" (consciousness)* and the *"known" (the phenomenal world)* arise simultaneously as aspects of a unified experiential event [279, 278]. Consciousness cannot exist without objects to be conscious of, just as no experienced world can manifest without consciousness to apprehend it. They represent not separate entities but complementary facets of a single, seamless process of aware experience [35].

This manuscript embraces the Law of Dependent Origination as its foundation, focusing particularly on the entanglement of the *Name and Form (Nāmarūpa)* dynamic. Our investigation centers on the relationship between the observer and the universe of physical phenomena—a universe that simultaneously constitutes the observer and serves as their environment. This encompasses both the chronogeometric structure of spacetime and the fundamental particles described by the Standard Model of Physics.

1.1.3 The Tetralemma: Reality's Four-Vertex Prism

The *tetralemma*, known in Sanskrit as the **Catuṣkoṭi चतुष्कोटि ("four corners")**, is a sophisticated logical structure that serves as a cornerstone of Madhyamaka Buddhist philosophy [15, 35]. Far from being a simple statement of facts, it is a powerful dialectical tool designed to systematically deconstruct our most deeply ingrained assumptions about the nature of existence. It challenges the very foundation of classical, binary logic—the idea that a proposition must be either true or false—by exploring a complete set of four possibilities [273, 16].

The four *corners* of the tetralemma are typically presented as a set of four exhaustive propositions concerning a given phenomenon:

1. *It is (Being):* The first corner affirms the existence of a thing, representing our everyday, common-sense view where objects have a solid, independent reality. The most direct Sanskrit term is Asti (अस्ति), the simple, affirmative third-person singular of the verb *to be*. The nominal or conceptual form is often given as Bhāva (भाव), meaning "being", "existence", or "state", or as Sat (सत्), meaning "the real."

2. *It is not (Not-Being):* The second corner posits the negation or non-existence of the thing, the simple opposite of the first position. This is directly translated as Nāsti (नास्ति), a contraction of *na asti* ("it is not"). The corresponding conceptual terms are Abhāva (अभाव), meaning "non-being" or "absence", and Asat (असत्), or "non-being."

3. *It both is and is not (Both Being and Not-Being):* The third corner entertains the seemingly contradictory possibility that a phenomenon can simultaneously exist and not exist, expressed in Sanskrit as Asti ca Nāsti ca (अस्ति च नास्ति च), where *ca* means "and." This challenges the classical law of non-contradiction, suggesting a reality where opposing states can co-exist [274]. A more philosophically dense term for this concept is the compound Sadasat (सदसत्), which combines being (*sat*) and non-being (*asat*) into a single notion.

4. *It Neither Is nor Is Not (Neither Being nor Not-Being, nor both Being and Not-Being):* The fourth and final corner, Naiva Asti na Nāsti (नैवास्ति न नास्ति), literally "neither is it, nor is it not", is the most profound [46]. While traditional interpretations see this as a simple "none of the above", the more profound understanding, particularly in the context of masters like Nāgārjuna, is that it represents a *categorical shift*. The treatise will demonstrate that *Naiva Asti na Nāsti* is not a simplistic negation *of* the first three positions at all, but alludes to a concept far more subtle and complex, a transcendence *beyond* each of the first three.

The Tetralemma as a Philosophical Lense

The great philosopher *Nāgārjuna* employed the tetralemma not to arrive at one of the four corners as a final answer, but to systematically demonstrate that *none of them* can adequately describe the *ultimate nature of reality* [17, 15]. By applying this four-fold analysis to fundamental concepts such as causation, motion, and the self, he revealed that any attempt to pin down a phenomenon with a fixed, inherent identity leads to logical paradoxes [274]. For example, when examining the concept of a "cause", Nāgārjuna would argue that an effect cannot be produced from itself (the first corner), from something other than itself (the second corner), from both (the third corner), or from neither (the fourth corner) [16]. By demonstrating the incoherence of all four possibilities, he leads the intellect to a profound conclusion: the very idea of a "cause" as an independently existing entity is a conceptual fiction.

The Path to Emptiness or Śūnyatā

The ultimate purpose of the tetralemma is to guide the mind toward an understanding of *emptiness* (*Śūnyatā*) [35]. It operates on dependently originated phenomena by demonstrating that any attempt to predicate an *intrinsic, ultimate nature (svabhāva)* upon them—using any of the four logical positions of affirming, negating, both, or neither—inevitably leads to irresolvable contradiction [279, 46]. The tetralemma thus reveals that all conditioned things are "empty" of such an independent existence. This "emptiness" is the very mark of *Dependent Origination*. Because things are empty of an inherent self, they are free to arise, interact, and cease in a dynamic, interdependent web of relationships. The failure of the four corners is not a failure of logic; it is a successful demonstration that our conceptual categories, which presuppose inherent independent existence, do not apply to a reality that is fundamentally entangled and relational [273].

1.1.4 The Quantum Revelation: A Tetralemmatic Journey

The profound intellectual upheaval of twentieth-century physics can be understood as a necessary journey through the four exhaustive propositions of the ancient tetralemma [15, 273]. It is as if the universe, when probed at its most fundamental level, compelled physicists to abandon the simple logic of objective reality and embrace a more subtle and paradoxical structure of existence. As this exploration will show, their discoveries already hinted at the

application of the tetralemma to understand the nature of reality, revealing a dynamic cycle from classical certainty to quantum potentiality and back again [35].

To appreciate the significance of this scientific journey, we must first look back to an ancient fork in the road of human thought. In the ancient world, humanity's quest to understand reality arrived at a great intersection. The questions were the same everywhere: What does it mean for something "to be"? What is the nature of nothingness? Can opposites exist at the same time? But from this single point, two profoundly different journeys began.

In the East, particularly in the philosophical schools of India, thinkers looked at the four great propositions of reality—that a thing *is*, that it *is not*, that it is *both*, and that it is *neither*—and chose to embrace them all. For them, the tetralemma was a complete compass for navigating the complexities of existence [15]. They saw the paradoxes of the third and fourth corners not as errors in logic, but as profound insights [46, 274]. They used these ideas as a sophisticated toolkit to deconstruct our common-sense reality, seeking to understand a world where opposites could coexist and where the ultimate truth might lie beyond all concepts of being and non-being [17, 35].

In the West, the Greek philosopher *Aristotle* stood at the same crossroads and saw the same paradoxes. But instead of embracing them, he chose to build a fortress against them. He declared that rational thought required absolute clarity. His *Law of Non-Contradiction* became an unbreakable wall against the third corner, and his *Law of the Excluded Middle* barred the fourth, insisting that a statement must be either true or false. For two thousand years, Western thought lived and thrived within this powerful fortress of binary logic, building the foundations of modern science, law, and philosophy [73]. In mathematics, this binary clarity was formalized via set theory's crisp membership relations [280].

The great irony of history is that the inheritors of Aristotle's tradition—the physicists of the twentieth century—used his flawless logic to build tools so powerful they could probe the very heart of matter. And there, in the quantum realm, they were stunned to find the ghosts of the ideas their philosophical ancestors had banished. They found a world of superposition where a particle behaved as if it were *both* a particle and a wave [281, 168]. They found a realm of pure potentiality where a property *neither* existed nor did not exist until it was measured—classical definiteness emerging only through interaction with the environment (decoherence) [282].

To describe the universe at its most fundamental level, they had to break out of Aristotle's fortress. Unknowingly, the pioneers of quantum mechanics found themselves charting a course with the same four-pointed compass that Eastern philosophy had been using all along, finally reuniting the two great paths of human thought at the very frontier of science [16, 35].

It is: The Classical World and its Negation

The journey begins with the *first corner: It is*. This is the thesis of classical physics and mathematics, a worldview resting on the bedrock of Sir Isaac Newton's mechanics [159]. It affirmed a deterministic,

clockwork universe where reality was objective, particles followed predictable trajectories, and logic was absolute [15, 273]. In this reality, an element *is* a member of a well-defined set, or it is not—there is no middle ground. This clean, binary logic, formalized in set theory, created a cosmos of clear lines and unambiguous boundaries [280]. It not only gave us the

laws that could plot the course of planets but also became the engine of our digital age, where every computation boils down to a choice between a one and a zero [283].

This powerful framework was shattered by the *second corner: It is not*. This represents the antithesis—the dawn of the quantum age, marked by phenomena that classical physics could not explain. When Max Planck reluctantly proposed that energy was not continuous but was emitted in discrete *quanta*, he was making a profound statement of negation [284]. Reality, at its core, was *not* the smooth continuum that classical intuition demanded, and the first crack in the classical foundation appeared.

It Both Is and Is Not: The Paradox of "Both/And"

This negation led inexorably to the *third corner: It both is and is not*. This is the domain of quantum paradox, where contradictory properties are found to coexist in a single entity. The quintessential example is *wave-particle duality*. A quantum object, like an electron, is revealed to be *both* a localized particle (*it is*) and a delocalized wave (*it is not*). The double-slit experiment provides the irrefutable evidence, where a single electron "seemed to pass through *both* slits simultaneously like a wave and interfere with itself" [281].

This paradoxical synthesis is given its most unsettling expression in the famous thought experiment of *Schrödinger's Cat*, which, when unobserved, is described by a wave function that represents it as being "simultaneously *alive and dead*" [171, 172, 173]. Until an observation is made, the cat exists in a state of pure superposition, a ghostly blend of both possibilities at once. The act of observation is what forces reality to choose, collapsing the

both/and state into the simple

is or

is not of our classical world—an emergence often explained in terms of decoherence [282].

It Neither Is nor Is Not: Transcending "Neither/Nor"

Yet, the deepest reality lies in the *fourth corner: It neither is nor is not*. This represents a transcendence of all prior categories, a state of pure potentiality where our very questions about reality fail. This is the nature of the unobserved quantum state. As *Heisenberg's uncertainty principle* revealed, an electron prior to measurement "simply does not possess a definite position and a definite momentum at the same time" [285]. Far from being just an unknown, the very category of "having" that property is inapplicable. This is powerfully affirmed by the principle of *Measurement as Creation*, where, as Pascual Jordan stated, "Observations not only disturb what is to be measured, they produce it" [194]. The property was *neither* there *nor* not there; it was brought into being.

We encounter this frontier elsewhere in modern physics. Consider two *entangled particles*. After interacting, they form a single, inseparable reality, even when flying apart to opposite ends of the universe [178, 183, 184]. One particle doesn't have a definite state on its own; it isn't *spin-up* nor is it *not spin-up*. Its identity is so completely tied to its partner that its properties are only defined within the relational system of both [3]. We meet this limit again when we ask what lies at the heart of a *black hole*. Is there a singularity? Is there not? The question itself may be meaningless, as this is the point where our language—the laws of physics—is torn apart [240, 7].

This same principle echoes in the abstract world of mathematics through *Gödel's Incompleteness Theorems*. These theorems prove that in any sufficiently complex logical system, there will always be statements that are true but can never be proven *within the rules of that system* [286]. Such a statement neither *is* provable nor *is not* provable; its status transcends the system's own framework. The ultimate expression of this transcendent view comes from Niels Bohr himself: *"There is no quantum world. There is only an abstract quantum physical description"* [193].

The Cycle of Reality and the Concept of Symmetry

The fourth corner describes the humbling edge of our knowledge, the point where the universe refuses to answer our questions in the terms we know how to ask them [3]. Finally, the very act of observation completes the cycle. The "collapse of the wave function", a central tenet of the Copenhagen interpretation, is the mechanism that forces reality to exit the subtle logic of the third and fourth corners [168, 169]. Upon measurement, the wave of potentiality instantly "collapses" into a single, definite state [195, 124], forcing a choice. The qubit becomes a 0 (*It is*) or a 1 (*It is not*) [287]. In contemporary accounts, the emergence of classical definiteness from quantum superposition is often analyzed via decoherence and einselection [282, 170]. The measurement, therefore, is the act that translates the transcendent and paradoxical nature of the quantum realm into the simple, binary logic of the classical world we perceive. The entire quantum process, from unobserved potentiality to definite reality, thus unfolds precisely along the ancient path of the tetralemma.

This revelation—that the fundamental processes of the universe trace the contours of this ancient four-fold logic—demands a re-interpretation. In *Nāgārjuna's* treatment, the tetralemma appears to allude to a profound concept, as if it were a blueprint for reality's underlying architecture. To translate this ancient formula into the language of modern physics, we must identify its core principle. This treatise proposes that the four corners are, in fact, distinct generalizations of a single, foundational concept: **Symmetry**. We must therefore redefine our understanding of **Symmetry in its holistic sense**. We reason that it should be liberated from the simple notion *of a singular* property of invariance, into a more complete, holistic architecture of reality—a system composed of four distinct but interdependent modes. This unified structure is best conceptualized through the geometric metaphor of a **tetrahedron**.

The **triangular base** of this prism represents the immanent logical plane. Its three vertices are the foundational modes of existence (see Section 1.2.7 for a formal definition and justification for the neologisms):

1. **Symmetry (Thesis):** The principle of identity (Definitions 2.1 and 2.12).
2. **Antisymmetry (Antithesis):** The principle of distinction.
3. **Parasymmetry (Synthesis):** The principle of coherent interaction and superposition (Section 2.2 and Definitions 2.85 and 2.94).

These three corners define the relational dynamics within a given system. The **apex** of the tetrahedron represents the fourth corner, **Holosymmetry** (Sections 2.3, 3.8 and 12.2). It

occupies a position transcendent to the base, connected to all three vertices yet existing on a higher structural level. From this apex, the overarching laws that govern the entire system emerge. It is the symmetry *of* the system itself, not just a state *within* it. Thus, **Symmetry**, in its fullest sense, is the tetrahedral whole—the indivisible union of the planar base and the transcendent apex. It is a complete, "four-fold jewel" whose facets describe the total architecture of reality, from simple identity to the unifying laws that govern the cosmos. To fully appreciate the power of this conceptual model, we turn to a physical analogy: the prism. Just as a physical prism takes what appears to be a single, unified beam of white light and reveals the rich, hidden spectrum of colors within, the conceptual "prism of symmetry" takes a seemingly singular phenomenon and reveals its full logical spectrum.

A single beam of sunlight appears pure and unified as it travels through air, moving in a straight line until it encounters a prism. At the glass surface its path changes by **refraction**, governed by Snell's law $n_1 \sin\theta_1 = n_2 \sin\theta_2$ [26, 288]. A deeper transformation occurs because the refractive index depends on wavelength: **dispersion** [289, 26]. Inside the prism, violet light (shorter wavelength, higher frequency) typically experiences a larger refractive index than red light and is therefore deviated more strongly (normal dispersion) [26, §3.6–3.7]—except very near absorption lines, where some materials exhibit *anomalous dispersion*; in the visible for common glasses the account above holds [289, §§2.5–2.6]. After refraction at the second face, the colors separate further, producing an ordered spectrum from red through violet [289, Ch. 8]. While dispersion "makes rainbows", prisms also serve other purposes: in binoculars and periscopes they rely on *total internal reflection* to redirect and erect images (minimizing dispersion) [26, §4.4, §6.3], whereas in spectrometers they deliberately exploit dispersion to split light by wavelength [289, 26, Ch. 8].

1.1.5 The Middle Way: A Narrative of Insight

The *tetralemma* represents a complete, tetradic net of logic, a philosophical prism designed to illuminate the very structure of conceptual thought. It maps every possible position the mind can adopt when using the dependently originated tools of language, signs, and symbols to reason about reality. The Buddha, in the foundational *Kaccānagotta Sutta*, diagnosed the root of this conceptual error: when we make absolute statements about the world, our reasoning invariably collapses into two ontological extremes—the assertion of absolute *existence* (atthitā), which leads to eternalism, or the assertion of absolute *non-existence* (natthitā), which leads to annihilationism [275]. This polarity is the fundamental duality the path of wisdom seeks to transcend.

This principle moves beyond abstract thought. The *Acela Sutta* demonstrates it practically through Kassapa's questions about suffering. The query, *"Is suffering created by oneself?"* implies a permanent, existing self (eternalism), while *"Is it created by another?"* implies a disconnected self (annihilationism). By rejecting both, the Buddha reveals that all phenomena arise not from a fixed entity but through the intricate web of *dependent origination* [276].

The Mahayana sutras elevate this principle to its ultimate expression. The *Heart Sūtra* crystallizes this insight in its famous declaration: *"Form is emptiness; emptiness is form."* [290] This is the Middle Way articulated as a statement of perfect non-duality, a direct path that cuts through the endless oscillation between the two extremes. The *Diamond Sūtra* then provides the methodological key, employing its powerful dialectical formula, *"What is called*

X, is not X, therefore it is called X," to deconstruct our habits of conceptual grasping [291]. It reveals that we give names not to independently existing things, but to relational processes.

The Position of Having No Position

The philosophical position of the Middle Way is unique in that its final aim is to deconstruct the mind's habit of clinging to *any* fixed conceptual view (dṛṣṭi), including its own. The great master Nāgārjuna, the chief architect of this school, famously stated that he has no thesis of his own to prove, for his method is to reveal the internal contradictions within all other positions that assume an intrinsic, independent reality (svabhāva) [278]. It is akin to a raft. The raft is a definite, well-constructed object (a philosophical position) that is absolutely necessary to cross a river. But once you have reached the other shore (enlightenment), you do not carry the raft on your back. Its ultimate purpose is to be transcended and let go of [277].

The Insight and its Quantum Parallel

From the early discourses to the grand vision of the Mahayana, the central insight remains unchanged: the Middle Way is a unique philosophical position whose ultimate purpose is to dismantle the very act of position-taking [17, 279]. This ancient wisdom finds its most startling and precise modern parallel in the quantum realm. To insist that a quantum state must be either '0' or '1' is to fall into the classical extremes, misapprehending its true nature which allows for a superposition of both [287, 282]. The error lies in settling into these two extremes, a conceptual fixation that traps the mind in an endless cycle. The path of wisdom, the Buddha taught, is a *Middle Way* that transcends this false dichotomy by understanding that a reality governed by the interdependent web of Dependent Origination can never be captured by the fixed, binary categories of our conceptual thought [278, 273].

1.1.6 Aristotle and The Story of a Thesis

Imagine the bustling intellectual world of ancient Greece, where ideas were traded in open forums and debated in shaded porticos. In this world, the word *thésis* (θέσις) was a simple one, meaning "a putting" or "a placing." This simple word carried an ancient echo, descending from a Proto-Indo-European root, $*d^{h}eh_{1}$-, which meant the physical act of setting something down [81, 292]. From this concrete origin grew its intellectual meaning: the common act of setting an idea forth for discussion, a proposition laid bare for others to see [293].

Then came *Aristotle*, a philosopher who saw a need for order and rigor in these sprawling debates. He looked at the simple act of *thésis* and forged it into a sharper tool of dialectic within his systematic treatment of argumentation; a thesis became a determinate position to be defended by reasons [294, 295]. In his hands, it transcended its everyday meaning: a thesis could be a bold or even paradoxical claim that challenged common opinion (*endoxa*) and demanded a disciplined defense within a structured inquiry [294, 295]. He transformed the word from a simple statement into a defensible intellectual position, the cornerstone of ordered debate in classical philosophy [294, 295].

This powerful concept—a central claim that must be rigorously defended—traveled through the ages. It echoed in the halls of Roman orators, was preserved in the scriptoriums

of medieval monasteries, and was reborn in the great universities of Europe. Today, when a doctoral candidate stands to defend their *thesis*, they continue this tradition: a single, novel proposition formally set forth and defended before experts—an institutional sense attested in the historical record of English usage [296].

1.1.7 The Debates of Ancient India

Journey back to the vibrant intellectual landscape of classical India, where scholars and ascetics gathered under banyan trees or in grand debate halls to challenge the very nature of reality. These were not casual conversations; they were crucibles of logic, formal, rule-based duels of the mind known as *vāda* (वाद) [33, 297, 18].

A debate would begin when a philosopher rose to address the assembly. They would start by making a bold, clear declaration—a precise statement they intended to prove. This opening proposition, the seed from which the entire argument would grow, was known as the *pratijñā* (प्रतिज्ञा) [33, 298, 18]. This was their thesis, the central claim upon which their intellectual honor rested. It could be a statement about the nature of the soul, the cause of suffering, or the fabric of the cosmos.

The Sanskrit *pratijñā* (प्रतिज्ञा) is a compound word, and both of its parts have clear PIE origins:

- *prati-* (प्रति-): a prefix meaning "against," "towards," or "in return," from the PIE form **proti-* with the sense of facing or moving towards [298, 81, 292].
- *jñā* (ज्ञा): a verbal root meaning "to know" or "to perceive," from the PIE root **ǵneh₃-* "to know," which is also the source of Greek *gnōsis* (γνῶσις) and English *know* [298, 81, 293].

When combined, the deep etymological meaning of *pratijñā* is something like "to know towards" or "to declare against" an opponent: a solemn public claim that forms the basis of the argument [298].

Once the *pratijñā* was stated, it had to be defended. The philosopher would proceed to build a fortress of logic around their claim, guided by the exacting principles of schools such as *Nyāya*. They would present a reason (*hetu*), support it with an undeniable, real-world example (*udāharaṇa*), and methodically construct a five-membered argument—*pratijñā, hetu, udāharaṇa, upanaya, nigamana*—designed to be unassailable [33, 18, 297].

The opponent would, in turn, scrutinize every link in this logical chain, testing it for fallacies and contradictions. The ultimate goal of a true *vāda* was something more profound than simple victory: the shared pursuit of truth (तत्त्वनिर्णय, *tattva-nirṇaya*) [33, 297]. The debaters were participants in a structured process designed to cut away confusion and reveal the core of the matter.

In this ancient tradition, we see a powerful parallel to the world of Aristotle. While separated by thousands of kilometers, both cultures arrived at the same fundamental conclusion: the surest path to knowledge is to put forth a clear, defensible claim and subject it to the purifying fire of rigorous, logical argument [294, 295, 18].

1.2 The Tetralemma of Algebra

1.2.1 The Definition of Thesis

A *Thesis* is a determinate, context-indexed position that affirms existence (Asti/Bhāva/Sat) and is normatively bound to a rigorous mode of defense—Aristotelian in the sense of a reasoned position suitable for dialectical scrutiny, and Nyāya in the sense that the *pratijñā* is to be validated by a methodical, multi-membered argument—so that its *epistemic warrant* derives from the coherence and validity of its logical support.

Definition 1.1 (Thesis (*Asti*/अस्ति; *Bhāva*/भाव; *Sat*/सत्; Greek *thésis*; Sanskrit *pratijñā*))**.** Fix a domain of discourse $\mathcal{D}$ and an immanent context $\mathcal{C}$ (criteria of individuation and admissible inference). A *Thesis* about a formula φ is a structured act

$$\mathbf{Th}(\varphi;\mathcal{C}) \;:=\; \Big\langle \underbrace{\exists^{\mathcal{C}} x\, \varphi(x)}_{\text{(Being) Asti/Bhāva/Sat}} \;,\; \underbrace{\mathcal{J}_A(\varphi)}_{\text{Aristotelian defense}} \;,\; \underbrace{\mathcal{J}_N(\varphi)}_{\text{Nyāya defense}} \Big\rangle,$$

subject to the following constitutive conditions:

1. **Ontological affirmation (Being).** The content asserts existence *relative to* $\mathcal{C}$—the "It is": a determinate item of discourse is affirmed as real (Asti), i.e., an instance of *bhāva*/*sat*. *(Catuṣkoṭi: first corner).*
2. **Determinacy and reference.** The affirmed item meets $\mathcal{C}$'s criteria of individuation and sustains stable reference adequate for logical manipulation (identity and non-contradiction hold *within* $\mathcal{C}$).
3. **Dialectical posture (Aristotle).** $\mathcal{J}_A(\varphi)$ is a position to be defended by reasons, i.e., fit for ordered debate and syllogistic support from suitable *endoxa*.
4. **Procedural obligation (Ancient India).** $\mathcal{J}_N(\varphi)$ instantiates the Nyāya five-membered proving scheme with *pratijñā* as the opening commitment:

$$\underbrace{\text{pratijñā}}_{\text{thesis}},\ \underbrace{\text{hetu}}_{\text{reason}},\ \underbrace{\text{udāharaṇa}}_{\text{example}},\ \underbrace{\text{upanaya}}_{\text{application}},\ \underbrace{\text{nigamana}}_{\text{conclusion}}.$$

Equivalently, writing $\exists^{\mathcal{C}}$ for context-relative existence and letting $\mathrm{Arg}_{A/N}$ denote well-formed Aristotelian/Nyāya arguments, we may say:

$$\mathbf{Th}(\varphi;\mathcal{C}) \text{ holds} \iff \big(\exists^{\mathcal{C}} x\, \varphi(x)\big) \wedge \big(\mathcal{J}_A(\varphi) \in \mathrm{Arg}_A\big) \wedge \big(\mathcal{J}_N(\varphi) \in \mathrm{Arg}_N\big).$$

Remarks. (i) *Thesis* unifies *Asti*/*Bhāva*/*Sat* (ontic affirmation), Greek *thésis* (a defended position), and Sanskrit *pratijñā* (the formally announced claim). (ii) It is explicitly *immanent* and context-relative; no claim of ultimate *svabhāva* is made. Its role is to secure determinacy and justify claimhood within $\mathcal{C}$; the thesis's *warrant*, not metaphysical truth simpliciter, turns on the adequacy of its defense.

Thesis, in this framework (Section 1.2.1 and Definition 1.1), is not a dogmatic "yes" but a *preference the system displays* for a particular mode. Formally it is the projector $P_T := |e_1\rangle\langle e_1|$ onto the privileged Thesis state $|e_1\rangle$ from the ontological duality basis (Definition 2.1), and

its "truth value" in a state ρ is the Born valuation $v_{\text{Thesis}}(\rho) = \text{Tr}(P_T\rho)$ (Definition 1.18). Intuitively, that number tells us how much of the system's identity presently aligns with the Thesis pattern—like a dimmer, not an on/off switch. The meaning of Thesis is thus *basis-defined*: it is the tendency to show up as $|e_1\rangle$ when we interrogate the system along the distinguished Thesis–Antithesis axis in the $(0, 1)$-sector (Definition 2.1). In this sense, to "affirm" the Thesis is to say, "given this instrument orientation, the system is disposed to register in this symmetry mode."

Operationally, Thesis becomes a *repeatable test*. Measure in the Thesis/Antithesis basis defined by $\{|e_1\rangle, |e_2\rangle\}$; the observed frequency of the $|e_1\rangle$ outcome approaches $v_{\text{Thesis}}(\rho)$ by the Born rule (Definitions 1.18 and 2.1). We can also enact Thesis as a *filter*: apply P_T to prepare or post-select states that realize the Thesis mode, then study how subsequent dynamics treat that assertion (e.g., unitaries commuting with P_T preserve it; those that rotate into the complementary direction redistribute its weight). This makes Thesis experimentally legible: a concrete knob (choice of basis), a concrete readout (projective/effect measurement), and a concrete number (the probability) that plays the role of truth in the dialectic semantics (Definition 1.18).

Finally, Thesis lives alongside its contrasts without contradiction. A generic ρ can give *nonzero weight to both* Thesis and Antithesis because "truth" here is a probabilistic disposition, not mutual exclusion (Definition 1.18); only in the classical limit $v_{\text{Thesis}} \to 1$ (or 0) do we recover crisp bivalence. States orthogonal to the Thesis–Antithesis plane—i.e., outside $\mathcal{H}_{(0,1)} \subset \mathbb{C}^4$—naturally instantiate *"Neither,"* signaling that the very question "Thesis or Antithesis?" is inapplicable to that preparation (Definition 2.1). Synthesis then enters as the *complementary probe* in the same sector, realized by the parasymmetric mode and its projector P_{para} (Section 2.2 and Definitions 2.16 and 2.17), with the same Born-valued semantics linking "degree of synthesis" to $\text{Tr}(P_{\text{para}}\rho)$ (Definition 1.18).

1.2.2 The Definition of Antithesis

An *Antithesis* is a determinate, context-indexed denial that withholds existence (Nāsti/Abhāva/Asat) and is normatively bound to a rigorous mode of refutation—Aristotelian in the sense of a reasoned negation suitable for dialectical scrutiny, and Nyāya in the sense that the asserted absence is to be validated by a methodical argument (with *pratijñā* now a negative claim)—so that its *epistemic warrant* derives from the coherence and validity of its logical and evidential support.

Definition 1.2 (Antithesis (*Nāsti*/नास्ति; *Abhāva*/अभाव; *Asat*/असत्; Greek *antíthesis*))**.** Fix a domain of discourse $\mathcal{D}$ and an immanent context $\mathcal{C}$ (criteria of individuation, admissible inference, and admissible loci of evaluation). Let $\Lambda_{\mathcal{C}}$ be the set of spatiotemporal loci sanctioned by $\mathcal{C}$, and let $\lambda \in \Lambda_{\mathcal{C}}$.

An *Antithesis* denying a formula φ at locus λ is a structured act

$$\mathbf{AntiTh}(\varphi; \mathcal{C}, \lambda) := \Big\langle \underbrace{\neg\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)}_{\text{(Not-Being) Nāsti / Abhāva / Asat}} , \underbrace{\mathcal{J}^{-}_{A}(\varphi)}_{\text{Aristotelian refutation}} , \underbrace{\mathcal{J}^{-}_{N}(\varphi; \lambda)}_{\text{Nyāya absence-justification}} \Big\rangle,$$

subject to the following constitutive conditions:

1. **Ontological denial (Not-Being).** The content asserts *absence relative to* $\mathcal{C}$ at λ: no admissible instance of φ is present there (*nāsti*); conceptually, this is *abhāva/asat*. *(Catuṣkoṭi: second corner).*
2. **Scope and determinacy.** The negative claim is well-scoped: (i) φ is well-formed under $\mathcal{C}$, (ii) the locus λ (and, when relevant, time window) is specified, and (iii) reference conditions for non-occurrence are fixed so that the denial is meaningful and testable within $\mathcal{C}$.
3. **Dialectical posture (Aristotle).** $\mathcal{J}_A^{\neg}(\varphi)$ provides reasons adequate for ordered debate: e.g., a direct negative demonstration ($\forall_\lambda^{\mathcal{C}} x\, \neg\varphi(x)$), an *elenctic* refutation of all admissible supports for φ, or a *reductio* showing φ entails impossibility within $\mathcal{C}$.
4. **Procedural obligation (Ancient India).** $\mathcal{J}_N^{\neg}(\varphi;\lambda)$ validates absence using Nyāya norms:
   - a five-membered argument with negative *pratijñā* (e.g., "the pot is not in the house"), accompanied by *hetu*, *udāharaṇa*, *upanaya*, and *nigamana*;
   - an account of *abhāva*-type as appropriate to λ: prior absence (*prāgabhāva*), posterior absence (*pradhva sābhāva*), mutual exclusion (*anyonyābhāva*), or absolute absence (*atyantābhāva*);
   - and, where admissible in $\mathcal{C}$, appeal to properly conditioned non-perception (*anupalabdhi*) or to inference from failure under satisfied enabling conditions.

Absolute vs. local denial. If the intent is *absolute* denial, then quantification ranges over all admissible loci:

$$\mathbf{AntiTh}_{\mathrm{abs}}(\varphi;\mathcal{C}) \text{ holds } \iff \forall\lambda \in \Lambda_{\mathcal{C}}\ \neg\exists_\lambda^{\mathcal{C}} x\, \varphi(x).$$

Equivalently. Writing $\exists_\lambda^{\mathcal{C}}$ for context- and locus-relative existence, and letting $\mathrm{Arg}_{A/N}^{\neg}$ denote well-formed Aristotelian / Nyāya *negative* arguments, we may say:

$$\mathbf{AntiTh}(\varphi;\mathcal{C},\lambda) \text{ holds } \iff \left(\neg\exists_\lambda^{\mathcal{C}} x\, \varphi(x)\right) \wedge \left(\mathcal{J}_A^{\neg}(\varphi) \in \mathrm{Arg}_A^{\neg}\right) \wedge \left(\mathcal{J}_N^{\neg}(\varphi;\lambda) \in \mathrm{Arg}_N^{\neg}\right).$$

Remarks. (i) *Antithesis* unifies *Nāsti/Abhāva/Asat* (ontic denial), Greek *antíthesis* (a reasoned counter-position), and the Nyāya–Navya-Nyāya analysis of absence. (ii) It is explicitly *immanent* and context-relative: it withholds existence only within $\mathcal{C}$ (and, if specified, λ), without asserting ultimate *asat*. Its *warrant*—not metaphysical truth simpliciter—turns on the adequacy of its refutation- and absence-justification.

Antithesis, in this scheme (Section 1.2.2 and Definition 1.2), is not a mere negation of Thesis but the system's *preference for distinction* along the same privileged axis. Formally it is the projector $P_A := |e_2\rangle\langle e_2|$ onto the Antisymmetry mode $|e_2\rangle$ selected by the ontological duality basis (Definition 2.1), with Born valuation $v_{\mathrm{Antithesis}}(\rho) = \mathrm{Tr}(P_A\rho)$ (Definition 1.18). Read intuitively, this number quantifies the system's *disposition to register as Antithesis* under the Thesis–Antithesis interrogation: a graded alignment, not an all-or-nothing verdict. In the bridging map, this is precisely the AntiSym $\leftrightarrow$ AntiTh corner correspondence, ensuring that the logical meaning and the quantum anchor co-move (Section 1.2.7).

Operationally, Antithesis is a *repeatable test* and a *filter*. Measuring in the $\{|e_1\rangle, |e_2\rangle\}$ basis, the long-run frequency of the $|e_2\rangle$ outcome converges to $v_{\text{Antithesis}}(\rho)$ by the Born rule (Definition 1.18); post-selection with P_A prepares the Antithesis mode for subsequent dynamics. Unitaries that commute with P_A conserve its valuation, whereas rotations in the $(0,1)$-sector redistribute weight between P_T and P_A. The local involutive duality operator $D^{(\mathfrak{B}_x)}$ makes the contrast exact: it swaps $|e_1\rangle \leftrightarrow |e_2\rangle$, thereby exchanging the roles of Thesis and Antithesis while acting trivially outside this sector (Section 2.1.2). In short, Antithesis is experimentally legible: a concrete basis, a concrete effect P_A, and a concrete number that plays the role of truth.

Finally, Antithesis *coexists* with Thesis without paradox once truth is read as *Born valuation*. Generic states in $\mathcal{H}_{(0,1)} = \text{span}\{|e_1\rangle, |e_2\rangle\}$ can carry nonzero weight for both P_T and P_A; only the classical limits $v_{\text{Antithesis}} \to 1$ or 0 recover bivalence. States orthogonal to $\mathcal{H}_{(0,1)}$ realize *"Neither,"* signaling the inapplicability of the Thesis/Antithesis query to that preparation. On the same plane, the parasymmetric and anti-parasymmetric modes provide the *complementary probes*: synthesis (Σ_x,–like) organizes the two tendencies, while anti-parasymmetry marks their dissonance; together they form a complete resolution of the $(0,1)$-sector (Sections 2.2.2 and 2.2.3).

1.2.3 The Definition of Synthesis

A *Synthesis* is a determinate, context-indexed co-commitment that simultaneously affirms and denies existence (Asti ca Nāsti ca; *Sadasat*) and is normatively bound to paired modes of defense—Aristotelian in the sense that both the positive and negative positions are furnished with reasoned arguments fit for dialectical scrutiny, and Nyāya in the sense that each side is validated by methodical, multi-membered arguments (with twin *pratijñās*)—such that its *epistemic warrant* derives from the coherence and validity of these opposed yet non-trivially co-tenable justifications.

Definition 1.3 (Synthesis)**. Synthesis** (*Asti ca Nāsti ca*/अस्ति च नास्ति च; *Sadasat*/सदसत्).

Fix a domain of discourse $\mathcal{D}$ and an immanent context $\mathcal{C}$ (criteria of individuation, admissible inference, and admissible loci of evaluation). Let $\Lambda_{\mathcal{C}}$ be the $\mathcal{C}$-sanctioned loci and let $\lambda \in \Lambda_{\mathcal{C}}$. The definition employs a *paraconsistent* consequence relation, denoted $\vdash_{\text{pc}}$, which is admissible in $\mathcal{C}$ (i.e., one that does not validate explosion).

A *Synthesis* regarding a formula φ at locus λ is a structured act

$$\mathbf{SynTh}(\varphi; \mathcal{C}, \lambda) := \Big\langle \underbrace{\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)}_{\text{(Being) Asti/Sat}}, \underbrace{\neg\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)}_{\text{(Not Being) Nāsti/Asat}}, \underbrace{\mathcal{J}^{+}_{\text{A}}(\varphi), \mathcal{J}^{-}_{\text{A}}(\varphi)}_{\text{Aristotelian paired defenses}}, \underbrace{\mathcal{J}^{+}_{\text{N}}(\varphi;\lambda), \mathcal{J}^{-}_{\text{N}}(\varphi;\lambda)}_{\text{Nyāya paired defenses}}, \underbrace{\Pi_{\text{pc}}}_{\text{nontriviality witness}} \Big\rangle,$$

subject to the following constitutive conditions:

1. **Co-affirmation (Both Being and Not-Being).** Both claims hold *at the same locus* λ under $\mathcal{C}$: $\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)$ and $\neg\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)$ are jointly endorsed. *(Catuṣkoṭi: third corner).*

2. **Scope hygiene (no equivocation).** The denotation of φ and the parameters of λ are fixed so that the "both" is not due merely to a shift of sense or locus; any aspectual refinements (e.g., mode, level, or respect) are explicit in $\mathcal{C}$.
3. **Paraconsistent discipline (nontriviality).** Π_{pc} is evidence that $\mathcal{C}$ employs a non-explosive consequence relation $\vdash_{\text{pc}}$ with a model or valuation v such that $v(\varphi) = \mathbf{B}$ (both true and false) and, for all ψ, it is not the case that $\{\varphi, \neg\varphi\} \vdash_{\text{pc}} \psi$.
4. **Dialectical posture (Aristotle, paired).** $\mathcal{J}^{+}_{\text{A}}(\varphi)$ provides reasons for the positive claim (e.g., syllogistic support from suitable *endoxa*); $\mathcal{J}^{-}_{\text{A}}(\varphi)$ provides reasons for the negative claim (e.g., direct negative demonstration, *elenchos*, or *reductio*). The pair is accompanied by a *co-tenability* argument showing that $\vdash_{\text{pc}}$ admits their joint maintenance without collapse.
5. **Procedural obligation (Ancient India, paired).** $\mathcal{J}^{+}_{\text{N}}(\varphi;\lambda)$ and $\mathcal{J}^{-}_{\text{N}}(\varphi;\lambda)$ are Nyāya five-membered arguments with positive and negative *pratijñā*, respectively, with appropriate use (where admissible) of perception, inference, testimony, and non-perception (*anupalabdhi*) to underwrite presence and absence.

Equivalently. Writing $\text{Arg}^{\pm}_{A/N}$ for well-formed positive/negative Aristotelian or Nyāya arguments under $\vdash_{\text{pc}}$, we may say:

$$\begin{aligned}\textbf{SynTh}(\varphi;\mathcal{C},\lambda) \text{ holds} \iff & \Big(\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x) \ \wedge\ \neg\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)\Big) \\ & \wedge\ \Big(\mathcal{J}^{+}_{\text{A}}(\varphi) \in \text{Arg}^{+}_{A} \wedge \mathcal{J}^{-}_{\text{A}}(\varphi) \in \text{Arg}^{-}_{A}\Big) \\ & \wedge\ \Big(\mathcal{J}^{+}_{\text{N}}(\varphi;\lambda) \in \text{Arg}^{+}_{N} \wedge \mathcal{J}^{-}_{\text{N}}(\varphi;\lambda) \in \text{Arg}^{-}_{N}\Big) \\ & \wedge\ \Pi_{\text{pc}}.\end{aligned}$$

Remarks. (i) *Synthesis* captures *Asti ca Nāsti ca* and the dense compound *Sadasat*: a true contradiction (a "glut") licensed within an immanent, paraconsistent fragment of $\mathcal{C}$. (ii) It remains *context-relative* and non-metaphysical in ambit: no claim is made about ultimate *svabhāva*; the status of φ hinges on admissible evidence and $\vdash_{\text{pc}}$'s non-explosive logic. (iii) For purely aspectual coexistence (different respects or modes) the construction reduces to a consistent pair indexed by aspects within $\mathcal{C}$; the present definition includes, but is not limited to, that weaker case.

Here, *Synthesis* names a mode of coherent organization, not a timid "halfway point." In the $(0,1)$-sector it is the equal-weight *normalized* superposition

$$\tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle + |\mathring{\mathbf{1}}\rangle\big),$$

and the associated projector P_{para} isolates exactly that component of any state—i.e., the *direction of dialectical co-alignment* of Symmetry with Antisymmetry (Section 2.2 and Definition 2.17). In the Born-valued semantics, its truth valuation is $v_{\text{Synthesis}}(\rho) = \text{Tr}(P_{\text{para}}\rho)$, so "how true the Synthesis is" becomes a measurable propensity rather than a bivalent verdict (Definition 1.18). Read this way, Synthesis is the system's *disposition to register* in the coherent $\tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle + |\mathring{\mathbf{1}}\rangle\big)$ mode when interrogated along the parasymmetric axis—precisely the Thesis–Antithesis plane's complementary probe (Definition 1.16).

Operationally, one treats Synthesis as a *repeatable test and filter*: the pair of projectors $\{P_{\text{para}}, P_{\text{antipara}}\}$ forms an orthogonal, complete resolution of the $(0,1)$-sector, so repeated trials directly estimate $v_{\text{Synthesis}}(\rho)$ while post-selection prepares the synthesized mode for subsequent dynamics. In these terms, Anti-parasymmetry supplies the *contrast class*: it projects onto the normalized $\frac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle - |\mathring{\mathbf{1}}\rangle\big)$, capturing modal dissonance; together, the two effects sum to the sector projector $P_{(0,1)}$, guaranteeing closure and basis-coherence with Thesis/Antithesis (Definition 2.18 and Section 2.2.2).

Beyond a single locus, Synthesis *becomes relation*. Bipartitely it is the Bell-like entangled mode $\frac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle_x|\mathring{\mathbf{1}}\rangle_{x'} + |\mathring{\mathbf{1}}\rangle_x|\mathring{\mathbf{0}}\rangle_{x'}\big)$ with projector $P^{(xx')}_{\text{para}}$, a distributed co-alignment that belongs to neither site individually (Definition 2.23 and Section 2.2.3). Multipartitely it generalizes to the W-like state $|\Psi^{(n)}_{\text{para}}\rangle$ with global projector $P^{(x_1\cdots x_n)}_{\text{para}}$, exhibiting permutation symmetry, genuine multipartite entanglement, and mixed marginals—i.e., a *collective* synthesis that is irreducibly nonlocal (Section 2.2.5, Definition 2.33, and eq. (2.29)).

1.2.4 The Definition of the Holothesis

A *Holothesis* is a determinate, context-indexed suspension that refuses both affirmation and denial of existence—*Naiva Asti na Nāsti* (नैवास्ति न नास्ति)—not as a mere "none of the above," but as a categorical shift in which the very *applicability* of the existential polarity (Being/Not-Being, and their co-tenability) is withdrawn. Its warrant is *metadialectical*: any such polarity-talk misfires at this level (often glossed in Indian traditions as *anirvacanīya* or *aprapañca*).

Definition 1.4 (Holothesis)**. Holothesis** (*Naiva Asti na Nāsti*/नैवास्ति न नास्ति).

Fix a domain of discourse $\mathcal{D}$ and an immanent context $\mathcal{C}$ (criteria of individuation, admissible inference, admissible loci). Let $\Lambda_{\mathcal{C}}$ be the $\mathcal{C}$-sanctioned loci and $\lambda \in \Lambda_{\mathcal{C}}$. Let $\mathsf{App}_{\mathcal{C}}(\chi)$ read "χ is semantically applicable in $\mathcal{C}$," with $\neg\mathsf{App}_{\mathcal{C}}(\chi)$ meaning "χ is inapplicable (ill-typed or presuppositionally failed) in $\mathcal{C}$." Finally, let $\Uparrow\colon \mathrm{Lang}(\mathcal{C}) \to \mathrm{Lang}(\mathcal{C}^{\Uparrow})$ be an admissible *lift* functor witnessing the categorical shift.

A Holothesis about φ at λ is the structured act

$$\mathrm{HoloThAct}_{\mathcal{C}}(\varphi;\lambda) := \Big\langle \underbrace{\neg\mathsf{App}_{\mathcal{C}}\big(\exists^{\mathcal{C}}_{\lambda} x\,\varphi(x)\big)}_{\text{existential inapplicability}}, \underbrace{\neg\mathsf{App}_{\mathcal{C}}\big(\neg\,\exists^{\mathcal{C}}_{\lambda} x\,\varphi(x)\big)}_{\text{negative inapplicability}}, \underbrace{\mathcal{J}^{\perp}_{\mathrm{A}}(\varphi)}_{\text{Aristotelian meta-justification}}, \underbrace{\mathcal{J}^{\perp}_{\mathrm{N}}(\varphi;\lambda)}_{\text{Nyāya meta-justification}}, \underbrace{\Uparrow}_{\text{shift witness}} \Big\rangle,$$

subject to the following constitutive conditions:

1. **Polar inapplicability (Neither Being nor Not-Being).** Both existential polarities fail at the same locus λ in $\mathcal{C}$:

$$\neg\mathsf{App}_{\mathcal{C}}\big(\exists^{\mathcal{C}}_{\lambda} x\,\varphi(x)\big) \;\wedge\; \neg\mathsf{App}_{\mathcal{C}}\big(\neg\,\exists^{\mathcal{C}}_{\lambda} x\,\varphi(x)\big).$$

   This is not a covert assertion of *neither* (a gap) nor of *both* (a glut), but a typed judgement of *inapplicability* of the polarity itself.

2. **Stability under admissible reparametrizations.** For any refinement $\mathcal{C}'$ reachable from $\mathcal{C}$ by admissible re-indexing of sense, respect, mode, or locus (including aspectual factorizations), the inapplicability persists:

$$\forall\, \mathcal{C}' \in \mathrm{Ref}(\mathcal{C}): \quad \neg \mathsf{App}_{\mathcal{C}'}\Big(\exists^{\mathcal{C}'}_{\lambda} x\, \varphi(x)\Big) \;\wedge\; \neg \mathsf{App}_{\mathcal{C}'}\Big(\neg\, \exists^{\mathcal{C}'}_{\lambda} x\, \varphi(x)\Big).$$

3. **Non-collapse to the earlier corners.** (i) Not to *Thesis*: $\nvdash\, \exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)$; (ii) not to *Antithesis*: $\nvdash\, \forall^{\mathcal{C}}_{\lambda} x\, \neg\varphi(x)$; (iii) not to *Synthesis*: no admissible consequence relation in $\mathcal{C}$ validates $\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x) \;\wedge\; \neg \exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)$.
4. **Dialectical posture (Aristotle, meta).** $\mathcal{J}^{\perp}_{\mathrm{A}}(\varphi)$ shows that attempts to force existential polarity here are *secundum quid/simpliciter* confusions, category mistakes (homonymy of *to be*), or require illicit shifts of predication base; hence "Is it or is it not?" is ill-posed *in* $\mathcal{C}$ for φ at λ.
5. **Procedural obligation (Nyāya, meta).** $\mathcal{J}^{\perp}_{\mathrm{N}}(\varphi; \lambda)$ provides a five-membered argument whose *pratijñā* is a *non-applicability claim*, with *hetu* (failed delimitor/avacchedaka or presupposition), *udāharaṇa* (a paradigm of category error), *upanaya* (mapping to the present case), and *nigamana* (concluding inapplicability); where relevant, it may also appeal to disciplined *tarka* to show that forcing the polarity leads to contradiction or vacuity.
6. **Shift witness (categorical lift).** The functor $\Uparrow$ maps φ to a stratum $\mathcal{C}^{\Uparrow}$ in which existential vocabulary is eliminated or reinterpreted so that $\Uparrow(\varphi)$ is evaluable without the polarity; composing back to $\mathcal{C}$ does not reintroduce it.

Equivalently. Let $\mathfrak{L}_{\mathcal{C}}$ be the family of admissible consequence relations in $\mathcal{C}$ (classical, paraconsistent, paracomplete, etc.). Then a Holothesis holds iff

$$\neg \mathsf{App}_{\mathcal{C}}\Big(\exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)\Big) \;\wedge\; \neg \mathsf{App}_{\mathcal{C}}\Big(\neg\, \exists^{\mathcal{C}}_{\lambda} x\, \varphi(x)\Big) \;\wedge\; \mathcal{J}^{\perp}_{\mathrm{A}}(\varphi) \in \mathrm{Arg}^{\perp}_{\mathrm{A}} \;\wedge\; \mathcal{J}^{\perp}_{\mathrm{N}}(\varphi; \lambda) \in \mathrm{Arg}^{\perp}_{\mathrm{N}} \wedge\; \Uparrow,$$

and, moreover, for every $\vdash \in \mathfrak{L}_{\mathcal{C}}$, neither the affirmative, the negative, nor their conjunction is derivable for φ at λ.

Remarks. (i) "Neither Being nor Not-Being" here is *not* the assertion of a third truth value in $\mathcal{C}$ but a typed *judgement of inapplicability* of the existential polarity at that site, stabilized by the categorical lift $\Uparrow$. (ii) This preserves the immanent/ultimate distinction: it makes no claim of ultimate *svabhāva*, only that, at this stratum, existence/non-existence talk is idle; the work is done by metadialectical justification rather than by hidden ontology. (iii) In contexts where an admissible aspectual re-indexation makes the polarity meaningful, the Holothesis *dissolves* (returns to one of the first three corners) via failure of Stability, as it should. (iv) The Holothesis is a *meta-justification* of the inapplicability of the existential polarity at λ in $\mathcal{C}$.

Here, the *Holothesis* names a meta-assertion: not "the system is in such-and-such mode," but "the system's *law of evolution* is being realized in a coherent superposition of alternatives—and we can test that." Concretely, holosymmetry lifts two complementary parasymmetric dynamics to a dual-register stage and lets a control qubit coherently *assign* which

register gets which law (U_G vs. U_N); preparing the control in a superposition entangles entire *evolutionary histories* rather than mere states (Definitions 2.102 and 2.108). In the tetrahedral picture this is the apex speaking about the whole base at once: a statement *about* Symmetry/Antisymmetry/Parasymmetry, not another point on their plane (Sections 2.3 and 3.8).

Operationally, the Holothesis is implemented by the controlled holosymmetric operator $\mathbf{U}_{\text{ctrl}}$ that branches the dual registers under the two lifted path-laws, followed by an interference/recombination and a measurement on the control. This architecture makes the control readout a visibility meter for "agreement" or "dissonance" between full histories (Definition 2.114 and Section 2.3.2); in the symmetric interferometer one can read off constructive vs. destructive interference directly from the control probabilities p_0, p_1, which depend on the overlap of the two global evolutions acting on the same input state (Sections 2.3.2 and 3.1.2). The preparation/readout gates $\mathbf{U}_{\text{prep}}, \mathbf{U}_{\text{read}}$ let us choose the control basis in which this global question is asked (Section 3.1).

Truth semantics follows the same rule as the other corners, but the *effect* is induced by the whole holosymmetric circuit: with control prepared in $|\mathbf{a}\rangle_c$ and read out in $|\mathbf{b}\rangle_c$, the Holothesis valuation on a register state ρ_{RR} is

$$v_{\text{Holothesis}}(\rho_{\text{RR}}) = \text{Tr}\Big(E^{(\mathbf{a}\to\mathbf{b})}_{\text{Holothesis}}\,\rho_{\text{RR}}\Big), \qquad E^{(\mathbf{a}\to\mathbf{b})}_{\text{Holothesis}} = \Big\langle \mathbf{a}\Big|_c\, \mathbf{U}^{\dagger}_{\text{holo}}\,(|\mathbf{b}\rangle\langle\mathbf{b}|_c \otimes \mathbb{I})\,\mathbf{U}_{\text{holo}}\,\Big|\mathbf{a}\Big\rangle_c,$$

as recorded in the Born-valued semantics (Definition 1.18). This keeps the Holothesis a *repeatable test*: choose the control basis $(\mathbf{U}_{\text{prep}}, \mathbf{U}_{\text{read}})$, run the interferometer, and estimate this probability from frequencies—now a number that quantifies "how true the Holothesis is" for that preparation. Note that what is superposed are *assignments of global dynamics*, not operation orders; the construction stays within standard controlled-unitary physics (Definition 2.114).

1.2.5 Tetralemma of Algebra

Definition 1.5 (Tetralemma of Algebra (Atomic Prismatic))**.** Let Th, AntiTh, SynTh, and HoloTh denote, respectively, the modalities *Thesis*, *Antithesis*, *Synthesis*, and *Holothesis* as already specified in Sections 1.2.1 to 1.2.4. The *Tetralemma of Algebra* (the *atomic prismatic*) is the ordered quadruple

$$\mathring{\mathbf{\Lambda}} := \Big\langle \mathsf{Th},\ \mathsf{AntiTh},\ \mathsf{SynTh},\ \mathsf{HoloTh} \Big\rangle$$

together with *exactly and only* the relations, constructions, and identifications that are stipulated within those four definitions, taken as a single coherent unit. Formally:

(a) (**No redefinition**) The internal content of each corner is *identical* to that given in its own definition; no additional axioms are imposed on $\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}$ beyond those already declared in Sections 1.2.1 to 1.2.4.

(b) (**Closure as a unit**) The atomic prismatic $\mathring{\mathbf{\Lambda}}$ is the *minimal* algebraic object containing the four corners and closed under the constructions already invoked in those definitions

(e.g. the oppositional/duality relation between Th and AntiTh insofar as it is specified there, the construction of SynTh from Th and AntiTh as specified there, and the meta-level role attributed to HoloTh as specified there).

(c) (**Atomicity**) $\overset{\circ}{\mathbf{\Lambda}}$ admits no nontrivial decomposition into a disjoint union of sub-*quadruples* preserving the relations inherited from the four definitions. Equivalently, there is no partition $\{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\} = U \uplus V$ with $U, V \neq \varnothing$ such that the inherited relations restrict to make both U and V into atomic prismatic units. Hence, in particular, there is no separation of $\{\mathsf{Th}, \mathsf{AntiTh}\}$ from $\{\mathsf{SynTh}, \mathsf{HoloTh}\}$ (or any other split) compatible with those relations.

(d) (**Morphisms, optional**) A *prismatic morphism* $f : \overset{\circ}{\mathbf{\Lambda}} \to \overset{\circ}{\mathbf{\Lambda}}{}'$ is a map that sends each corner to its namesake,

$$f(\mathsf{Th}) = \mathsf{Th}', \quad f(\mathsf{AntiTh}) = \mathsf{AntiTh}', \quad f(\mathsf{SynTh}) = \mathsf{SynTh}', \quad f(\mathsf{HoloTh}) = \mathsf{HoloTh}',$$

and preserves *all* relations, constructions, and identifications that appear in Sections 1.2.1 to 1.2.4. Two units are *isomorphic* if there exists a bijective prismatic morphism between them.

We will refer to $\overset{\circ}{\mathbf{\Lambda}}$ as the *Tetralemma of Algebra*.

Remark 1.6 (Terminology Convention and Prismatic Intent)**.** Throughout, "atomic" means *indecomposable under corner-respecting decompositions* as in Definition 1.5(c) (and not "having atoms" in the order-theoretic sense). "Prismatic" means that admissible maps act on the *entire* unit $\overset{\circ}{\mathbf{\Lambda}}$, transporting the Fourfold *as a whole*; a map that preserves the corners only piecemeal while violating the inherited inter-corner constructions is not prismatic.

Remark 1.7 (Universality/Minimality of the Tetralemma of Algebra)**.** Let $\mathcal{C}$ be the class of all structures Q whose *underlying carrier set* $|Q|$ satisfies

$$\{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\} \subseteq |Q|,$$

and whose operations/relations are *exactly* those induced by Sections 1.2.1 to 1.2.4 (restricted to $|Q|$). Then the atomic prismatic $\overset{\circ}{\mathbf{\Lambda}}$ of Definition 1.5 is obtained by intersecting carrier sets and restricting relations:

$$|\overset{\circ}{\mathbf{\Lambda}}| \;=\; \bigcap_{Q \in \mathcal{C}} |Q|, \qquad \text{with the inherited operations/relations restricted to } \; |\overset{\circ}{\mathbf{\Lambda}}|.$$

In particular, $\overset{\circ}{\mathbf{\Lambda}}$ is contained in every $Q \in \mathcal{C}$ and is unique with this property. This packages the "closure as a unit" and "no redefinition" clauses as a universal (initial) characterization, without adding structure to the corners.

Proposition 1.8 (Invariance Under Admissible Dualities and Reindexings)**.** *Let $\mathcal{D}$ denote the duality involution of Section 1.2.6 exchanging $\mathsf{Th} \leftrightarrow \mathsf{AntiTh}$ and fixing $\mathsf{SynTh}, \mathsf{HoloTh}$, and let ρ be any admissible reindexing that preserves the four corner-definitions. Then*

$$\mathcal{D}(\overset{\circ}{\mathbf{\Lambda}}) = \overset{\circ}{\mathbf{\Lambda}} \qquad \textit{and} \qquad \rho(\overset{\circ}{\mathbf{\Lambda}}) = \overset{\circ}{\mathbf{\Lambda}}.$$

Proof. By Proposition 1.12, $\{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\}$ is preserved (indeed, pointwise fixed up to the $\mathsf{Th} \leftrightarrow \mathsf{AntiTh}$ swap) under $\mathcal{D}$ and any admissible ρ. By Definition 1.5, $\overset{\circ}{\mathbf{\Lambda}}$ is the minimal object that (i) contains these corners and (ii) is closed under exactly the inherited constructions used in their definitions. Since $\mathcal{D}$ and ρ preserve both the corners and those constructions, they send any $Q \in \mathcal{C}$ to another element of $\mathcal{C}$, hence fix the intersection $\bigcap_{Q\in\mathcal{C}} |Q|$ and the restricted relations; minimality forces equality. □

Corollary 1.9 (Initiality/Uniqueness of Prismatic Morphisms out of the Atomic Prismatic)**.** *For every $Q \in \mathcal{C}$ there exists a unique* prismatic morphism $f : \overset{\circ}{\mathbf{\Lambda}} \to Q$.

Proof. Existence: the inclusion of carriers $|\overset{\circ}{\mathbf{\Lambda}}| \subseteq |Q|$ respects the inherited relations by construction, giving a prismatic morphism. Uniqueness: any prismatic morphism must agree with this inclusion on the four named corners and is determined on the closure generated by them; minimality of $\overset{\circ}{\mathbf{\Lambda}}$ then forces equality. □

1.2.6 The Axiom of Duality and its Self-Similar Nature

Axiom 1.10 (Axiom of Duality)**.** Fix an immanent context $\mathcal{C}$ with its criteria of individuation and admissible inference. Let $\mathcal{U}_\mathcal{C}$ denote the class of primitive ontological states. There exists an involution (duality operator)

$$\mathbf{D}_\mathcal{C} : \mathcal{U}_\mathcal{C} \to \mathcal{U}_\mathcal{C}, \qquad \mathbf{D}_\mathcal{C}^2 = \mathrm{Id},$$

which, for the designated primitives, satisfies $\mathbf{D}_\mathcal{C}\big(|\overset{\circ}{\mathbf{0}}\rangle\big) = |\overset{\circ}{\mathbf{1}}\rangle$ and $\mathbf{D}_\mathcal{C}\big(|\overset{\circ}{\mathbf{1}}\rangle\big) = |\overset{\circ}{\mathbf{0}}\rangle$. In a reality governed by dependent origination (*pratītyasamutpāda*), the assertion of any state $s \in \mathcal{U}_\mathcal{C}$ entails the conceptual co–arising of its complement:

$$\mathsf{Affirm}_\mathcal{C}(s) \implies \mathsf{Conceive}_\mathcal{C}\big(\mathbf{D}_\mathcal{C}(s)\big),$$

where $\mathsf{Affirm}_\mathcal{C}(s)$ abbreviates "s is affirmed in $\mathcal{C}$," and $\mathsf{Conceive}_\mathcal{C}(t)$ abbreviates "t is (minimally) conceptually available in $\mathcal{C}$." Accordingly, intelligible ontological content is minimally *dyadic*:

$$\langle s, \mathbf{D}_\mathcal{C}(s)\rangle \text{ is the minimal semantic unit of duality,}$$

i.e., neither element is semantically autonomous in isolation.

Operational Ties to the Four Corners

Fix a locus λ in context $\mathcal{C}$. Let

$$\mathsf{Status}_\mathcal{C}(\varphi, \lambda) \in \{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\}$$

denote the corner–status (Thesis, Antithesis, Synthesis, Holothesis) of a well-formed formula φ at λ (as defined earlier). Define the *status dualization*

$$\Delta_\mathcal{C} : \{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\} \to \{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\}$$

by

$$\begin{aligned} \Delta_\mathcal{C}(\mathsf{Th}) &= \mathsf{AntiTh}, & \Delta_\mathcal{C}(\mathsf{SynTh}) &= \mathsf{SynTh}, \\ \Delta_\mathcal{C}(\mathsf{AntiTh}) &= \mathsf{Th}, & \Delta_\mathcal{C}(\mathsf{HoloTh}) &= \mathsf{HoloTh}. \end{aligned}$$

so that $\Delta_\mathcal{C}^2 = \mathrm{Id}$.

Compatibility with Object-level Duality.

For every well-formed φ at λ,

$$\mathsf{Status}_{\mathcal{C}}\Big(\mathbf{D}_{\mathcal{C}}(\varphi),\lambda\Big) \;=\; \Delta_{\mathcal{C}}\Big(\mathsf{Status}_{\mathcal{C}}(\varphi,\lambda)\Big).$$

Interpretation. Dualization exchanges *Thesis* and *Antithesis*, while *Synthesis* and *Holothesis* are self-dual (the former licenses a disciplined both/and; the latter marks inapplicability of the polarity).

Self-similarity (Scale-free Replication)

Duality propagates uniformly across levels of discourse.

Definition 1.11 (Lifts of Duality)**.**

(i) **Object level.** $\mathbf{D}_{\mathcal{C}}$ acts on primitive ontological states $s \in \mathcal{U}_{\mathcal{C}}$ with $\mathbf{D}_{\mathcal{C}}^2 = \mathrm{Id}$.

(ii) **Propositional level.** Extend $\mathbf{D}_{\mathcal{C}}$ to formulas by dualizing primitive predicates and distributing through logical form (De Morgan–compatible) in a way that respects the admissible consequence relation of $\mathcal{C}$ (classical or paraconsistent, as specified). We write $\varphi^{\mathbf{D}}$ for the result of this homomorphic extension.

(iii) **Corner level.** The *status dualization* $\Delta_{\mathcal{C}}$ on $\{\mathsf{Th},\mathsf{AntiTh},\mathsf{SynTh},\mathsf{HoloTh}\}$ is given by

$$\begin{aligned} \Delta_{\mathcal{C}}(\mathsf{Th}) &= \mathsf{AntiTh}, & \Delta_{\mathcal{C}}(\mathsf{SynTh}) &= \mathsf{SynTh},\\ \Delta_{\mathcal{C}}(\mathsf{AntiTh}) &= \mathsf{Th}, & \Delta_{\mathcal{C}}(\mathsf{HoloTh}) &= \mathsf{HoloTh}. \end{aligned}$$

so that $\Delta_{\mathcal{C}}^2 = \mathrm{Id}$, and status assignment respects duality:

$$\mathsf{Status}_{\mathcal{C}}(\varphi,\lambda) = X \implies \mathsf{Status}_{\mathcal{C}}(\varphi^{\mathbf{D}},\lambda) = \Delta_{\mathcal{C}}(X).$$

(iv) **Meta level.** In the *Holothesis* case, introduce an applicability predicate $\mathsf{App}_{\mathcal{C}}(\cdot)$. Duality leaves *inapplicability* invariant:

$$\neg\mathsf{App}_{\mathcal{C}}(\chi) \implies \neg\mathsf{App}_{\mathcal{C}}\Big(\mathbf{D}_{\mathcal{C}}(\chi)\Big).$$

Object-level Instance

Let $|\mathring{\mathbf{0}}\rangle$ be any primitive ontological state (see Definition 1.16) and define $|\mathring{\mathbf{1}}\rangle \coloneqq \mathbf{D}_{\mathcal{C}}\Big(|\mathring{\mathbf{0}}\rangle\Big)$. Then

$$|\mathring{\mathbf{0}}\rangle \;\leftrightarrow\; |\mathring{\mathbf{1}}\rangle, \qquad \mathbf{D}_{\mathcal{C}}\Big(|\mathring{\mathbf{1}}\rangle\Big) = |\mathring{\mathbf{0}}\rangle,$$

and the dyad $\Big(|\mathring{\mathbf{0}}\rangle, |\mathring{\mathbf{1}}\rangle\Big)$ is semantically primary.

Self-similar Lifts (Equivalent Restatement).

(i) Propositional lift. Extend $\mathbf{D}_{\mathcal{C}}$ homomorphically to formulas; denote the dual by $\varphi^{\mathbf{D}}$.

(ii) Tetralemma-status lift. There is an involution $\Delta_{\mathcal{C}}$ with $\Delta_{\mathcal{C}}(\mathsf{Th}) = \mathsf{AntiTh}$, $\Delta_{\mathcal{C}}(\mathsf{AntiTh}) = \mathsf{Th}$, and $\Delta_{\mathcal{C}}(\mathsf{SynTh}) = \mathsf{SynTh}$, $\Delta_{\mathcal{C}}(\mathsf{HoloTh}) = \mathsf{HoloTh}$; status assignment respects duality: $\mathsf{Status}_{\mathcal{C}}(\varphi, \lambda) = X \Rightarrow \mathsf{Status}_{\mathcal{C}}(\varphi^{\mathbf{D}}, \lambda) = \Delta_{\mathcal{C}}(X)$.

(iii) Meta-lift (informal). Duality preserves admissible inference and typing rules (schematically, $\mathbf{D}_{\mathcal{C}} : \mathcal{R} \to \mathcal{R}$ with $\mathbf{D}_{\mathcal{C}}^2 = \mathrm{Id}$ on the rule set $\mathcal{R}$).

Proposition 1.12 (Self-similarity and closure)**.** *For any admissible reindexing $\mathcal{C} \to \mathcal{C}'$ (change of aspect, respect, mode, or locus) that preserves dependent origination, there exists a unique duality operator $\mathbf{D}_{\mathcal{C}'}$ such that*

$$F \circ \mathbf{D}_{\mathcal{C}} \;=\; \mathbf{D}_{\mathcal{C}'} \circ F$$

for the induced functor $F : \mathcal{U}_{\mathcal{C}} \to \mathcal{U}_{\mathcal{C}'}$. Hence duality is scale-free *and the set*

$$\{\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}\}$$

is closed and pointwise fixed under repeated dualization.

Sketch. Involution and functoriality determine $\mathbf{D}_{\mathcal{C}'}$ uniquely by conjugation. By definition of $\Delta_{\mathcal{C}}$, Thesis and Antithesis are exchanged; Synthesis and Holothesis quantify over—or deny the applicability of—the polarity itself and are therefore invariant under the swap. Closure follows. □

(iv) Meta-level lift — Minimal, proof-theoretic statement Let $\mathsf{Judg}_{\mathcal{C}}$ denote the set of well-formed judgments in context $\mathcal{C}$, $\mathsf{Deriv}_{\mathcal{C}}$ the derivations built from an admissible rule set $\mathcal{R}_{\mathcal{C}}$, and write $\Gamma \vdash_{\mathcal{C}} \varphi$ for a judgment. There exists an involution $\widehat{\mathbf{D}}_{\mathcal{C}}$ (the *meta-duality*) acting on rules, derivations, and judgments such that:

- **M1** (*Action on judgments*) $\widehat{\mathbf{D}}_{\mathcal{C}}(\Gamma \vdash_{\mathcal{C}} \varphi) \;=\; \widehat{\mathbf{D}}_{\mathcal{C}}(\Gamma) \;\vdash_{\mathcal{C}}\; \varphi^{\mathbf{D}}$, with $\widehat{\mathbf{D}}_{\mathcal{C}}^2 = \mathrm{Id}$.
- **M2** (*Action on rules*) For every inference rule $r \in \mathcal{R}_{\mathcal{C}}$, $\widehat{\mathbf{D}}_{\mathcal{C}}(r) \in \mathcal{R}_{\mathcal{C}}$ and r is admissible iff $\widehat{\mathbf{D}}_{\mathcal{C}}(r)$ is admissible.
- **M3** (*Action on derivations*) $\widehat{\mathbf{D}}_{\mathcal{C}}$ maps derivations to derivations by structural recursion, preserves derivability, and commutes with substitution/renaming: $\widehat{\mathbf{D}}_{\mathcal{C}}(\varphi[\sigma]) = \widehat{\mathbf{D}}_{\mathcal{C}}(\varphi)[\,\widehat{\mathbf{D}}_{\mathcal{C}}(\sigma)\,]$.
- **M4** (*Status coherence*) If $\mathsf{Status}_{\mathcal{C}}(\varphi, \lambda) = X$ (as in *(iii)*), then $\mathsf{Status}_{\mathcal{C}}(\varphi^{\mathbf{D}}, \lambda) = \Delta_{\mathcal{C}}(X)$.
- **M5** (*Conservativity & non-explosion*) $\widehat{\mathbf{D}}_{\mathcal{C}}$ preserves consistency and any stipulated non-explosive consequence relation $\vdash_{\mathrm{pc}}$ used in Synthesis:

$$\Gamma \nvdash_{\mathrm{pc}} \bot \;\Leftrightarrow\; \widehat{\mathbf{D}}_{\mathcal{C}}(\Gamma) \nvdash_{\mathrm{pc}} \bot.$$

(iv) Meta-level lift — Categorical/autoequivalence form (optional) Let **Ctx** be the category whose objects are immanent contexts $\mathcal{C}$ and whose morphisms are admissible refinements $f : \mathcal{C} \to \mathcal{C}'$. Let **Der** be the category of derivations (proofs) internal to contexts, with a forgetful functor $U : \mathbf{Der} \to \mathbf{Ctx}$ sending each derivation to its home context. There

exists a strict endofunctor $\mathfrak{D} : \mathbf{Ctx} \to \mathbf{Ctx}$ and a lifted endofunctor $\widehat{\mathfrak{D}} : \mathbf{Der} \to \mathbf{Der}$ such that

$$U \circ \widehat{\mathfrak{D}} = \mathfrak{D} \circ U, \qquad \mathfrak{D}^2 \cong \mathrm{Id}_{\mathbf{Ctx}}, \qquad \widehat{\mathfrak{D}}^2 \cong \mathrm{Id}_{\mathbf{Der}},$$

with natural isomorphisms witnessing involutivity. On objects/states and formulas, $\widehat{\mathfrak{D}}$ restricts to the object- and propositional-dualities of *(i)* and *(ii)*; on statuses it restricts to $\Delta_{\mathcal{C}}$ of *(iii)*. Moreover, $\widehat{\mathfrak{D}}$ preserves admissibility of rules, cut-elimination, and commutes with substitution and reindexing (functorial coherence squares commute).

Relation to Ket-Notation Dyads

Fix an immanent context $\mathcal{C}$ and its duality operator $\mathbf{D}_{\mathcal{C}}$ (Axiom 1.10).

Definition 1.13 (Dyadic constructor and orbit)**.** For any admissible state/content $s \in \mathcal{U}_{\mathcal{C}}$, define the *ordered dyad*

$$\mathfrak{D}_{\mathcal{C}}(s) \;:=\; \langle s, \mathbf{D}_{\mathcal{C}}(s) \rangle \;\in\; \mathcal{U}_{\mathcal{C}} \times \mathcal{U}_{\mathcal{C}}.$$

The associated *unordered dyad* is the $\mathbb{Z}_2$–orbit of s under the action generated by $\mathbf{D}_{\mathcal{C}}$:

$$[\![s]\!]_{\mathcal{C}} \;:=\; \{\, s, \mathbf{D}_{\mathcal{C}}(s) \,\}.$$

Principle 1.1 (Dyadic intelligibility)**.** *There is a predicate* $\mathrm{Int}_{\mathcal{C}}(\cdot)$ *("is a minimal intelligible semantic unit in* $\mathcal{C}$*") such that, for all admissible* $s \in \mathcal{U}_{\mathcal{C}}$*,*

$$\mathrm{Int}_{\mathcal{C}}\Big(\mathfrak{D}_{\mathcal{C}}(s)\Big) \quad \textit{holds}, \qquad \neg\,\mathrm{Int}_{\mathcal{C}}(s) \quad \textit{and} \quad \neg\,\mathrm{Int}_{\mathcal{C}}\Big(\mathbf{D}_{\mathcal{C}}(s)\Big) \textit{ hold.}$$

Equivalently, any unary semantic evaluation in $\mathcal{C}$ *factors through dyadization: there exist a (partial) map*

$$\mathcal{M}_{\mathcal{C}}^{(2)} :\; \mathcal{U}_{\mathcal{C}} \times \mathcal{U}_{\mathcal{C}} \rightharpoonup \mathbb{M} \quad \textit{and a total map} \quad F : \mathbb{M} \to \mathbb{N}$$

such that whenever the unary evaluation $\mathcal{M}_{\mathcal{C}}(s)$ *is defined,*

$$\mathcal{M}_{\mathcal{C}}(s) \;=\; F\Big(\mathcal{M}_{\mathcal{C}}^{(2)}\Big(\mathfrak{D}_{\mathcal{C}}(s)\Big)\Big)\,.$$

That is, intelligibility attaches to the dyad rather than to a singleton.

Example 1.14 (Kets and conceptual pairs)**.** If $\mathbf{D}_{\mathcal{C}}\Big(|\mathring{\mathbf{0}}\rangle\Big) = |\mathring{\mathbf{1}}\rangle$, then

$$\mathfrak{D}_{\mathcal{C}}\Big(|\mathring{\mathbf{0}}\rangle\Big) = \Big\langle\, |\mathring{\mathbf{0}}\rangle,\; |\mathring{\mathbf{1}}\rangle \,\Big\rangle.$$

At the conceptual level (lift (ii) of Definition 1.11),

$$\begin{aligned} \mathfrak{D}_{\mathcal{C}}(\text{Existence}) &= \langle \text{Existence}, \text{Non-Existence} \rangle, \\ \mathfrak{D}_{\mathcal{C}}(\text{Self}) &= \langle \text{Self}, \text{Not-Self} \rangle, \\ &\vdots \\ \mathfrak{D}_{\mathcal{C}}(\text{Real}) &= \langle \text{Real}, \text{Un-Real} \rangle. \end{aligned}$$

Higher-order dyads (e.g., $\langle \text{Duality}, \text{Non-Duality} \rangle$) follow from the propositional and meta lifts in Definition 1.11.

Corner-selections on Dyads

Fix an immanent context $\mathcal{C}$, a locus λ, and write $\mathfrak{D}_{\mathcal{C}}(\varphi) = \langle L(\varphi),\ R(\varphi)\rangle$ for a well-formed φ (with $R(\varphi) = \mathbf{D}_{\mathcal{C}}(L(\varphi))$). Define selection functionals

$$\mathsf{Sel}_{\mathsf{Th}}, \mathsf{Sel}_{\mathsf{AntiTh}}, \mathsf{Sel}_{\mathsf{SynTh}}, \mathsf{Sel}_{\mathsf{HoloTh}} : \Big(\mathcal{U}_{\mathcal{C}} \times \mathcal{U}_{\mathcal{C}}\Big) \times \Lambda_{\mathcal{C}} \longrightarrow \mathcal{P}\Big(\{L(\varphi), R(\varphi)\}\Big)$$

by

$$\mathsf{Sel}_{\mathsf{Th}}\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big) = \{L(\varphi)\}, \qquad \mathsf{Sel}_{\mathsf{AntiTh}}\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big) = \{R(\varphi)\},$$
$$\mathsf{Sel}_{\mathsf{SynTh}}\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big) = \{L(\varphi), R(\varphi)\}, \qquad \mathsf{Sel}_{\mathsf{HoloTh}}\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big) = \varnothing,$$

where the last case reflects the *inapplicability* of existential polarity in the Holothesis.

Proposition 1.15 (Compatibility with the four corners)**.** *At any admissible locus λ, the corner–statuses align with the selectors as follows:*

(Thesis) $\mathrm{Thesis}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \exists^{\mathcal{C}}_{\lambda} x\, \mathrm{L}(\varphi)(x)$.

(Antithesis) $\mathrm{Antithesis}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \exists^{\mathcal{C}}_{\lambda} x\, \mathrm{R}(\varphi)(x)$.

(No identification of R with $\neg\,\mathrm{L}$ is assumed.)

(Synthesis) $\mathrm{Synthesis}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \Big(\exists^{\mathcal{C}}_{\lambda} x\, \mathrm{L}(\varphi)(x)\Big) \wedge \Big(\exists^{\mathcal{C}}_{\lambda} y\, \mathrm{R}(\varphi)(y)\Big)$.

The joint commitment is stably maintainable under $\vdash_{\mathrm{pc}}$.

(Holothesis) $\mathrm{Holothesis}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \neg\,\mathrm{App}_{\mathcal{C}}\Big(\exists^{\mathcal{C}}_{\lambda} x\, \mathrm{L}(\varphi)(x)\Big) \wedge \neg\,\mathrm{App}_{\mathcal{C}}\Big(\exists^{\mathcal{C}}_{\lambda} y\, \mathrm{R}(\varphi)(y)\Big)$.

Thus the four corners are realized as, respectively, left *selection,* right *selection,* both *selections (paraconsistently licensed), and* no *selection due to meta-level inapplicability.*

Sketch. By Definition 1.13, $\mathfrak{D}_{\mathcal{C}}(\varphi)$ packages the dual pair $\langle L, R\rangle$. Thesis selects L, hence affirms an instance of $L(\varphi)$; Antithesis selects R, hence affirms an instance of $R(\varphi)$. Synthesis selects both, so both existential claims hold; stability under $\vdash_{\mathrm{pc}}$ ensures non-explosion even if L and R collide at a locus. In the Holothesis case, $\mathsf{Sel}_{\mathsf{HoloTh}} = \varnothing$ and Definition 1.11 (iv) gives invariance of inapplicability under dualization, hence the two $\neg\mathsf{App}_{\mathcal{C}}$ clauses. Closure and alignment with statuses follow. □

Paraconsistent Compatibility

When $\mathcal{C}$ admits a paraconsistent (see Section 1.2.3) consequence relation $\vdash_{\mathrm{pc}}$, *Synthesis* corresponds to asserting *both* coordinates of $\mathfrak{D}_{\mathcal{C}}(s)$ without explosion, while *Holothesis* corresponds to meta-level *inapplicability* for both coordinates, which is preserved by dualization:

$$\mathsf{SynTh}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \Big(\exists^{\mathcal{C}}_{\lambda} x\, L(\varphi)(x)\Big) \ \wedge\ \Big(\exists^{\mathcal{C}}_{\lambda} y\, R(\varphi)(y)\Big),$$
$$\text{with } \{\exists^{\mathcal{C}}_{\lambda} x\, L(\varphi)(x),\ \exists^{\mathcal{C}}_{\lambda} y\, R(\varphi)(y)\} \nvdash_{\mathrm{pc}} \bot;$$
$$\mathsf{HoloTh}_{\mathcal{C}}(\varphi; \lambda) \Rightarrow \neg\mathsf{App}_{\mathcal{C}}\Big(\exists^{\mathcal{C}}_{\lambda} x\, L(\varphi)(x)\Big) \ \wedge\ \neg\mathsf{App}_{\mathcal{C}}\Big(\exists^{\mathcal{C}}_{\lambda} y\, R(\varphi)(y)\Big).$$

and, since $\Delta_{\mathcal{C}}(\mathsf{SynTh}) = \mathsf{SynTh}$ and $\Delta_{\mathcal{C}}(\mathsf{HoloTh}) = \mathsf{HoloTh}$,

$$\mathsf{Status}_{\mathcal{C}}(\mathbf{D}_{\mathcal{C}}(\varphi), \lambda) = \mathsf{Status}_{\mathcal{C}}(\varphi, \lambda) \quad \text{for } \mathsf{Status} \in \{\mathsf{SynTh}, \mathsf{HoloTh}\}.$$

Notational Refinement

To visually mark *conceptual co-implication/co-arising*, write

$$s \;\dashv\vdash_{\mathcal{C}}\; \mathbf{D}_{\mathcal{C}}(s)$$

and reserve $\leftrightarrow$ for material biconditionals *inside* $\mathcal{C}$.

Compact Axiom Schema.

$$\forall s \in \mathcal{U}_{\mathcal{C}}: \quad \mathsf{Affirm}_{\mathcal{C}}(s) \;\Rightarrow\; \mathsf{Conceive}_{\mathcal{C}}\Big(\mathbf{D}_{\mathcal{C}}(s)\Big), \qquad \mathbf{D}_{\mathcal{C}}^2 = \mathrm{Id}, \qquad \Delta_{\mathcal{C}}^2 = \mathrm{Id},$$

$$\mathsf{Status}_{\mathcal{C}}(\mathbf{D}_{\mathcal{C}}(\varphi), \lambda) = \Delta_{\mathcal{C}}\Big(\mathsf{Status}_{\mathcal{C}}(\varphi, \lambda)\Big), \qquad \neg\mathsf{App}_{\mathcal{C}}(\chi) \;\Rightarrow\; \neg\mathsf{App}_{\mathcal{C}}\Big(\mathbf{D}_{\mathcal{C}}(\chi)\Big).$$

(The last two clauses capture status-compatibility and invariance of inapplicability.)

The Example Set of Dyads

$$\begin{aligned}\mathcal{E}_{\text{duality}} := \Big\{&\mathfrak{D}_{\mathcal{C}}(\text{Existence}),\ \mathfrak{D}_{\mathcal{C}}(\text{Eternalism}),\ \mathfrak{D}_{\mathcal{C}}(\text{Self}),\ \mathfrak{D}_{\mathcal{C}}(\text{Emptiness}),\\ &\mathfrak{D}_{\mathcal{C}}(\text{Continuous}),\ \mathfrak{D}_{\mathcal{C}}(\text{Duality}),\ \mathfrak{D}_{\mathcal{C}}(\text{Created}),\ \mathfrak{D}_{\mathcal{C}}(\text{Finite}),\\ &\mathfrak{D}_{\mathcal{C}}(\text{Form}),\ \mathfrak{D}_{\mathcal{C}}(\text{Time}),\ \mathfrak{D}_{\mathcal{C}}(\text{True}),\ \mathfrak{D}_{\mathcal{C}}(\text{Positive}),\ \mathfrak{D}_{\mathcal{C}}(\text{Real})\Big\}.\end{aligned}$$

Illustrative pairs. (1) Existence / Non-Existence, (2) Eternalism / Nihilism, (3) Self / Not-Self, (4) Emptiness / Non-Emptiness, (5) Continuous / Discontinuous, (6) Duality / Non-Duality, (7) Created / Un-Created, (8) Finite / Infinite, (9) Form / Formlessness, (10) Time / Timelessness, (11) True / False, (12) Positive / Negative, (13) Real / Un-Real.

1.2.7 The Fourfold Dialectic Algebra of Symmetry

The foundational logic of the IQR framework is a generative, tetradic system termed the *Fourfold Dialectic Algebra of Symmetry*. It bridges the ancient catuṣkoṭi, Aristotelian dialectic, and our modern formalizations of Thesis, Antithesis, Synthesis, and the Holothesis, while preserving the ontological state realizations that anchor the quantum constructions.

Definition 1.16 (Fourfold Dialectic Algebra of Symmetry)**.** For each Primordial Quantum Singularity $\mathfrak{B}_x$ (Definition 1.25), let

$$\mathcal{H}_{\text{mod}}(\mathfrak{B}_x) \quad \text{and} \quad \{\hat{\mathcal{F}}_\alpha(x)\}_{\alpha\in\{0,1,p,s\}}$$

denote, respectively, the modal fibre and the four symmetry *modes* acting on it. The *Fourfold Dialectic $*$-algebra of Symmetry at $\mathfrak{B}_x$* is the $*$-subalgebra

$$\mathcal{A}_x^{(4)} \;:=\; {}^*\mathrm{alg}\left\langle \hat{\mathcal{F}}_0(x), \hat{\mathcal{F}}_1(x), \hat{\mathcal{F}}_p(x), \hat{\mathcal{F}}_s(x) \right\rangle \;\subseteq\; \mathcal{B}\Big(\mathcal{H}_{\text{mod}}(\mathfrak{B}_x)\Big),$$

whose four generators are *congruent*, via the dialectic–quantisation correspondence, to the modernised tetralemma modalities (Thesis, Antithesis, Synthesis, Holothesis). Congruence here means the correspondence preserves the involutive duality, synthesis rules, and meta-level structure (Definitions 1.1 to 1.4, 2.1 and 2.12):

1. **Symmetry** $\cong$ **Thesis** (Definition 1.1). *Ontological representative (ray):*

$$|\mathring{\mathbf{0}}\rangle_x \in \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x), \qquad \text{carried by } \hat{\mathcal{F}}_0(x).$$

2. **Antisymmetry** $\cong$ **Antithesis** (Definition 1.2). *Ontological anti-representative (ray):*

$$|\mathring{\mathbf{1}}\rangle_x \in \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x), \qquad \text{carried by } \hat{\mathcal{F}}_1(x),$$

with the global involutive duality implementing $|\mathring{\mathbf{0}}\rangle_x \leftrightarrow |\mathring{\mathbf{1}}\rangle_x$ (Definitions 2.1 and 2.12).

3. **Parasymmetry** $\cong$ **Synthesis** (Definition 1.3). *Canonical ontological superposition (phase–conventioned):*

$$\frac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle_x + |\mathring{\mathbf{1}}\rangle_x\big)$$

generated/selected by $\hat{\mathcal{F}}_p(x)$ (cf. Section 2.2 and Definitions 2.85 and 2.94). (More general relative phases are gauge-equivalent under local U(1) choices.)

4. **Holosymmetry** $\cong$ **Holothesis** (Definition 1.4). *Meta-representational coupling:*

$$\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{0}}\mathring{\mathbf{1}}}(x) \quad \text{carried by } \hat{\mathcal{F}}_s(x),$$

encoding the holosymmetric meta-structure that coheres the corners at the operator level (Sections 2.3, 3.8 and 12.2).

We refer to $(\mathcal{A}_x^{(4)}; \hat{\mathcal{F}}_0, \hat{\mathcal{F}}_1, \hat{\mathcal{F}}_p, \hat{\mathcal{F}}_s)$ as the *Fourfold Dialectic Algebra of Symmetry at* $\mathfrak{B}_x$, with ontological representatives preserved by the correspondence to the modernised tetralemma.

Remark 1.17 (On congruence and gauge)**.** The symbol "$\cong$" indicates a structure-preserving identification of logical modalities with quantum modes that (i) intertwines the global involutive duality, (ii) respects synthesis/parasymmetry construction, and (iii) lifts to meta-level holosymmetry. Representatives such as $|\mathring{\mathbf{0}}\rangle_x$, $|\mathring{\mathbf{1}}\rangle_x$ are defined up to local frame and phase; statements are gauge-covariant under the bundle connection (Lemma 4.270).

The Fourfold Dialectic Algebra says, in effect, that each Primordial Quantum Singularity (Definition 1.25) carries a *four-mode compass* whose points line up one-to-one with the modernized tetralemma. The congruence map Φ identifies Symmetry $\leftrightarrow$ Thesis, Antisymmetry $\leftrightarrow$ Antithesis, Parasymmetry $\leftrightarrow$ Synthesis, and Holosymmetry $\leftrightarrow$ Holothesis, while *preserving the ontological anchors* (Corollary 1.21). That preservation clause matters: it guarantees that anything we build on the logical side—states, projectors, or processes—can be transported to the symmetry side *without changing what the system ontologically "is."* In practice, $|\mathring{\mathbf{0}}\rangle$ and $|\mathring{\mathbf{1}}\rangle$ realize the Thesis/Antithesis modes (Definition 2.1); their coherent blend $\frac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle + |\mathring{\mathbf{1}}\rangle\big)$ realizes Synthesis; and the holosymmetric meta-symbol $\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{0}}\mathring{\mathbf{1}}}$ marks the Holothesis "about the whole" rather than another point on the same plane (Sections 2.3 and 3.8).

Intuitively, the four modes are *tests we can actually run*, tied to the Born-valued semantics (Section 1.2.9 and Definition 1.18). Thesis/Antithesis correspond to measuring the distinguished axis fixed by the ontological duality basis (a Σ_z-like readout); Synthesis

is the *complementary probe* that asks whether the system organizes those two tendencies coherently (a Σ_x-like readout); and Holothesis is a *controlled interferometric readout* that asks a meta-question about which global evolution is coherently realized. Because "truth" is the expectation value $v(\rho; P) = \mathrm{Tr}(P\rho)$, these corners are not mutually exclusive by fiat: a single preparation ρ can carry simultaneous warranted degrees for Thesis and Antithesis, or land outside their plane (the "Neither" region), with Synthesis and Holothesis revealing different aspects of that situation.

Finally, calling it an *algebra* highlights the structural rules that keep everything consistent. Operators that commute with the Thesis projector P_T (respectively P_A) conserve that stance; the local duality involution swaps Thesis $\leftrightarrow$ Antithesis while acting trivially off their sector; and the parasymmetric/anti-parasymmetric pair resolves the $(0, 1)$-sector without "leakage," ensuring closure with the Thesis/Antithesis frame. At the reasoning level, the *prism behavior* (Definition 1.23 and Proposition 1.24) explains how different contexts select different subsets of modes: classical contexts pick one of the poles, paraconsistent contexts allow Synthesis alongside them *without explosion*, and meta-contexts license Holosymmetry when the base-level polarity is inapplicable. In short, the definition packages a bridge (logic $\leftrightarrow$ symmetry), a semantics (Born-valued truth), and an operational reading (concrete tests) into one compact scaffold.

1.2.8 A Prism for Discourse: Classical Logic as a Special View

Classical binary logic furnishes a powerful fortress of certainty: propositions are either true or false; contradiction is disallowed; there is no middle ground [73, 280]. The fourfold dialectic framework does not tear down this fortress; it *re-situates* it. Classical logic appears when the world is interrogated along a single axis—*Thesis/Antithesis*—while two further, indispensable axes are also available: *Synthesis* ("both, coherently") and *Holothesis* ("neither," more deeply "structure at the whole") [15, 273, 17]. Formally, these correspond to *Symmetry*, *Antisymmetry*, *Parasymmetry*, and *Holosymmetry* in the Fourfold Dialectic Algebra (Section 1.2.7).

The central shift is to treat logic as *diagnostic interrogation*. A single discourse—like white light through a prism—is refracted into four complementary facets. Each facet returns a quantitative *degree of warrant* $v \in [0, 1]$ via Born valuation, so "truth" is an operational propensity rather than a bare bivalent label (Section 1.2.9).

The Formal Core and Its Operational Meaning

Let the state of warrant be a density operator ρ on a Hilbert space. Each facet $\square \in \{\mathrm{T}, \mathrm{A}, \mathrm{S}, \mathrm{H}\}$ corresponds to a positive operator $E_\square$ (an *effect*). The facet's reading is the Born value

$$v_\square(\rho) = \mathrm{Tr}(E_\square \rho) \in [0, 1]$$

(Definition 1.18). Concretely, in the distinguished $(0, 1)$-sector, *Thesis* and *Antithesis* are the projectors $P_T = |e_1\rangle\langle e_1|$, $P_A = |e_2\rangle\langle e_2|$ (Definitions 1.18 and 2.1).

Synthesis is realized as the *parasymmetric* projector $P_{\text{para}} = |+\rangle\langle +|$ with $|+\rangle = (|e_1\rangle + |e_2\rangle)/\sqrt{2}$ (Definition 2.94). The pair $\{P_{\text{para}}, P_{\text{antipara}}\}$ is orthogonal and *locally complete* on the $(0, 1)$-sector:

$$P_{\text{para}} + P_{\text{antipara}} = P_{(0,1)} = P_T + P_A,$$

so repeated trials directly estimate $v_{\text{S}}(\rho) = \text{Tr}(P_{\text{para}}\rho)$ (Definition 2.94). *Holothesis* is a *global* facet. Operationally it is an effect $E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ induced by a holosymmetric controlled unitary that compares *entire histories* (alternative global evolutions) and reads the result back on the registers; its valuation is

$$v_{\text{H}}(\rho) = \text{Tr}\Big(E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}\rho\Big)$$

(eq. (3.36) and Definition 1.18).

What "both" means (and what it doesn't)

Synthesis is *not dialetheism*. It does not say "P and $\neg P$" are literally both true; rather, it detects *coherent co-presence*—quantum superposition—via an interference-sensitive projector P_{para}. Its signal vanishes for mixtures and grows with phase coherence, exactly the quantum distinction between superpositions and statistical ensembles [287, 282]. In multipartite settings, Synthesis scales naturally to *relational* structure (Bell-like parasymmetric states), realizing "both" as distributed entanglement (Section 2.2.3).

What "neither" means—and the deeper role of H

Holothesis can register "neither true nor false" when the T/A frame is inapplicable, but its essence is subtler: it is an *implementation-invariant, system-level interrogation*. It asks whether the discourse's status survives *swaps of whole mechanisms*—e.g., exchanging "globally coupled" vs "decoupled" evolutions in dual registers and comparing them coherently (Section 3.8.1). Equivalences under control-basis rotations, register swaps, and common conjugations show that H is about *the whole architecture*, not local content ($H4$, Definition 3.18).

Why the classical slice reappears

This expansion does not violate classical laws; it *contains* them. The *Axiom (Principle) of Duality* ensures that T/A form a complete pair on their domain: $P_T + P_A = P_{(0,1)}$. Hence, on that sector, $v_T + v_A = 1$: the *Excluded Middle* is recovered (Section 1.2.6 and Definition 2.100).

The *Law of Non-Contradiction* is recovered in the *commuting/decohered limit*: when interrogations commute or decoherence kills off-diagonals, the S-facet carries no independent signal and T/A become crisp, so "both-true" cannot be registered ($P_T P_A = 0$) [282]. In that regime, the fourfold prism collapses to the classical fortress. (See also the local completeness and orthogonality identities for $P_{\text{para}}, P_{\text{antipara}}$ in Definition 2.94.)

What the prism yields beyond the fortress

- *Resolution vs coherence.* T/A resolve local alternatives; S reads *coherent coexistence* (superposition). Classical logic can distinguish only mixtures, not coherence [287].
- *Local vs global.* H interrogates *architecture*—invariance under exchanging entire mechanisms—via holosymmetric effects (eq. (3.36)).

- *Quantification.* All four facets return *Born-valued* degrees of warrant, making "truth" an operational propensity (Definition 1.18).

How to read a discourse with the prism

Given ρ, perform four complementary interrogations:

1. *T/A:* $v_T(\rho), v_A(\rho)$ — the classical slice (Definition 1.18).
2. *S:* $v_S(\rho) = \mathrm{Tr}(P_{\mathrm{para}}\rho)$ — coherence of the T/A split (Definition 2.94).
3. *H:* $v_H(\rho) = \mathrm{Tr}(E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}\rho)$ — global, implementation-invariant status (eq. (3.36)).

These questions are not mutually reducible; they resolve different aspects of structure (cf. the logic→algebra→representation pipeline Section 1.4.2).

Classical laws in their regime of validity

Nothing here negates classical laws *in their proper regime*:

1. *Non-Contradiction* emerges as a theorem for *commuting interrogations* and *decohered states*—the geometry where S has no distinctive signal [282].
2. *Excluded Middle* is recovered when only T/A valuations are meaningful and crisp; Duality guarantees $P_T + P_A = P_{(0,1)}$ (Definition 2.100).

Thus classical logic is the bright central band of a broader spectrum. Where contexts commute and interference vanishes, the prism narrows to the fortress. Where coherence and global structure matter, the additional facets—*Synthesis* and *Holothesis*—let us register *coherent coexistence* and *holistic invariants*, in line with the empirical grammar of quantum phenomena [168, 287, 282] and the philosophical insight of the catuṣkoṭi [15, 46, 17].

1.2.9 Born-Valued Semantics for the Four Corners

Definition 1.18 (Dialectic Truth as Born Valuation)**.** Let

$$M \in \{\text{Thesis}, \text{Antithesis}, \text{Synthesis}, \text{Holothesis}\}.$$

Associate to each corner a quantum *effect* E_M (a positive semidefinite operator with $0 \le E_M \le \mathbb{I}$) on the relevant Hilbert space. For any density operator ρ, the *truth value* (degree of warrant) of M in state ρ is

$$v_M(\rho) := \mathrm{Tr}(E_M\,\rho) \in [0,1].$$

Schema. For any effect P representing one of the four corners (projector or general POVM element),

$$v(\rho; P) := \mathrm{Tr}(P\,\rho) \in [0,1]. \tag{1.2}$$

When P is a projector and $\rho = |\psi\rangle\langle\psi|$, this reduces to $v(\rho; P) = \|P|\psi\rangle\|^2$.. Concretely, in the Symmetry–Antisymmetry sector $\mathcal{H}_{(0,1)} = \mathrm{span}\{|e_1\rangle, |e_2\rangle\}$ (cf. Definition 2.1):

$$E_{\text{Thesis}} := P_T := |e_1\rangle\langle e_1|, \qquad E_{\text{Antithesis}} := P_A := |e_2\rangle\langle e_2|.$$

For Synthesis, with $|+\rangle := (|e_1\rangle + |e_2\rangle)/\sqrt{2}$,

$$E_{\text{Synthesis}} := P_S := |+\rangle\langle +|.$$

For Holothesis (a meta-level choice measured via the holosymmetric control), fix a holosymmetric unitary $\mathbf{U}_{\text{holo}}$ on the control $\mathcal{H}_c$ and dual-register $\mathcal{H}_{\text{RR}}^{(2n)}$ (cf. Sections 2.3 and 3.8). Preparing the control in $|\mathbf{a}\rangle_c$ and reading out in $|\mathbf{b}\rangle_c$, the induced *effect* on the register is

$$E_{\text{Holothesis}}^{(\mathbf{a}\to\mathbf{b})} := \Big\langle \mathbf{a}\Big|_c \mathbf{U}_{\text{holo}}^\dagger \left(|\mathbf{b}\rangle\langle\mathbf{b}|_c \otimes \mathbb{I}\right) \mathbf{U}_{\text{holo}} \Big|\mathbf{a}\Big\rangle_c,$$

so that the measured Holothesis valuation for a register state ρ_{RR} is

$$v_{\text{Holothesis}}(\rho_{\text{RR}}) = \text{Tr}\Big(E_{\text{Holothesis}}^{(\mathbf{a}\to\mathbf{b})}\, \rho_{\text{RR}}\Big).$$

Remark 1.19 (Operational notes)**.** (i) For composite configurations, local effects extend by identity on the other factors; e.g. $P_T^{(x_i)} := |e_1\rangle\langle e_1|_{x_i} \otimes \mathbb{I}_{\text{rest}}$. (ii) The four effects are associated to *different tests* and need not form a single POVM simultaneously; incompatibility is expected. (iii) Numerical "truth values" are probabilities (Born rule), not amplitudes.

Lemma 1.20 (Bridge Map: Symmetry modes $\leftrightarrow$ Tetralemma corners)**.** *Let*

$$\Phi : \{\text{Sym}, \text{AntiSym}, \text{ParaSym}, \text{HoloSym}\} \xrightarrow{\cong} \{\text{Th}, \text{AntiTh}, \text{SynTh}, \text{HoloTh}\}$$

be the bijection $\Phi(\text{Sym}) = \text{Th}$, $\Phi(\text{AntiSym}) = \text{AntiTh}$, $\Phi(\text{ParaSym}) = \text{SynTh}$, $\Phi(\text{HoloSym}) = \text{HoloTh}$. *Write* $\mathfrak{D}_{\mathcal{C}}(\varphi) = \langle L(\varphi), R(\varphi)\rangle$ *for the dyad and let* Sel_{Th}, $\text{Sel}_{\text{AntiTh}}$, $\text{Sel}_{\text{SynTh}}$, $\text{Sel}_{\text{HoloTh}}$ *be the corner selections of Proposition 1.15. Define mode selections by congruence:*

$$\text{Sel}_{\text{Sym}} := \text{Sel}_{\text{Th}}, \quad \text{Sel}_{\text{AntiSym}} := \text{Sel}_{\text{AntiTh}}, \quad \text{Sel}_{\text{ParaSym}} := \text{Sel}_{\text{SynTh}}, \quad \text{Sel}_{\text{HoloSym}} := \text{Sel}_{\text{HoloTh}}.$$

Then for all admissible λ *and* φ,

$$\text{Sel}_M\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big) = \text{Sel}_{\Phi(M)}\Big(\mathfrak{D}_{\mathcal{C}}(\varphi); \lambda\Big).$$

Moreover, if $\Delta_{\mathcal{C}}$ *is the dualization on corners (Axiom 1.10), there exists the symmetry-side involution*

$$\begin{aligned} \Sigma :& \{\text{Sym}, \text{AntiSym}, \text{ParaSym}, \text{HoloSym}\} \to \{\cdots\}, \\ \Sigma(\text{Sym}) &= \text{AntiSym}, \\ \Sigma(\text{AntiSym}) &= \text{Sym}, \\ \Sigma(\text{ParaSym}) &= \text{ParaSym}, \\ \Sigma(\text{HoloSym}) &= \text{HoloSym}. \end{aligned}$$

such that the diagram commutes: $\Delta_{\mathcal{C}} \circ \Phi = \Phi \circ \Sigma$.

Corollary 1.21 (State/meta representations preserved)**.** *Under the correspondence of Lemma 1.20 the ontological representations agree:*

$$\begin{aligned}\mathrm{Rep}(\mathrm{Sym}) &= |\mathring{\mathbf{0}}\rangle,\\ \mathrm{Rep}(\mathrm{AntiSym}) &= |\mathring{\mathbf{1}}\rangle,\\ \mathrm{Rep}(\mathrm{ParaSym}) &= \tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle + |\mathring{\mathbf{1}}\rangle\big),\\ \mathrm{Rep}(\mathrm{HoloSym}) &= {}_{\mathring{\mathbf{0}}}\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{1}}}.\end{aligned}$$

Hence all quantum-mechanical realizations/constructions attached to the corners carry over verbatim to the symmetry modes.

Remark 1.22 (Ontological vs. conventional quantum states)**.** The ontological states above are pre-geometric logical primitives; conventional quantum states are emergent structures built from their superposition/entanglement.

The Fourfold Symmetry

Definition 1.23 (Symmetry as a four-mode logical prism)**.** Let

$$\mathsf{Modes} := \{\mathrm{Sym}, \mathrm{AntiSym}, \mathrm{ParaSym}, \mathrm{HoloSym}\} \quad \text{and}$$
$$\Phi : \mathsf{Modes} \xrightarrow{\cong} \{\mathrm{Th}, \mathrm{AntiTh}, \mathrm{SynTh}, \mathrm{HoloTh}\}$$

be the congruence $\Phi(\mathrm{Sym}) = \mathrm{Th}$, $\Phi(\mathrm{AntiSym}) = \mathrm{AntiTh}$, $\Phi(\mathrm{ParaSym}) = \mathrm{SynTh}$, $\Phi(\mathrm{HoloSym}) = \mathrm{HoloTh}$. Preserve the ontological anchors

$$\begin{aligned}\mathrm{Rep}(\mathrm{Sym}) &= |\mathring{\mathbf{0}}\rangle,\\ \mathrm{Rep}(\mathrm{AntiSym}) &= |\mathring{\mathbf{1}}\rangle,\\ \mathrm{Rep}(\mathrm{ParaSym}) &= \tfrac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle + |\mathring{\mathbf{1}}\rangle\big),\\ \mathrm{Rep}(\mathrm{HoloSym}) &= {}_{\mathring{\mathbf{0}}}\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{1}}}.\end{aligned}$$

For any well-formed φ and locus λ, define the *symmetry spectrum* selected by the context $\mathcal{C}$:

$$\mathrm{Spec}_{\mathcal{C}}(\varphi,\lambda) \;:=\; \Big\{\, m \in \mathsf{Modes} \;:\; \mathrm{Sel}_{\Phi(m)}\big(\mathfrak{D}_{\mathcal{C}}(\varphi);\lambda\big) \text{ holds} \,\Big\}.$$

Proposition 1.24 (Prism behavior by reasoning regime)**.** *(i) If $\mathcal{C}$ is classical (non-paraconsistent) and presumes applicability of the existential polarity, then* $\mathrm{Spec}_{\mathcal{C}}(\varphi,\lambda) \in \Big\{\{\mathrm{Sym}\},\{\mathrm{AntiSym}\}\Big\}$.
(ii) If $\mathcal{C}$ admits a paraconsistent $\vdash_{\mathrm{pc}}$, then ParaSym *may also be selected jointly with* Sym *and* AntiSym *(non-explosively).*
(iii) If $\mathcal{C}$ licenses meta-level inapplicability (Holothesis), then $\mathrm{HoloSym} \in \mathrm{Spec}_{\mathcal{C}}(\varphi,\lambda)$ *and the existential polarity is inapplicable to both coordinates.*

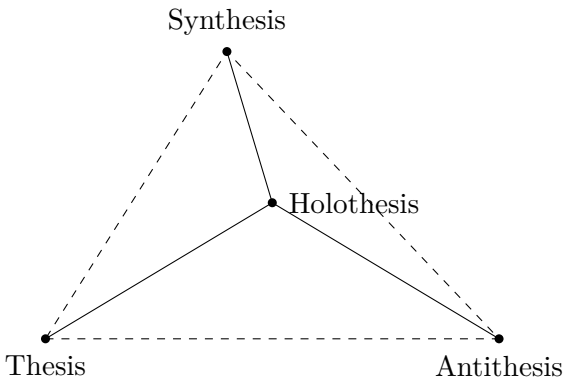

Figure 1.1: The four corners (tetrahedron) of the dialectic.

Etymology and Semantics

The word "symmetry" traces its origins back to the Ancient Greek term *symmetria* (συμμετρία) [293, 299]. This word is a compound of two Greek roots: *syn* (σύν), meaning "together" or "with", and *metron* (μέτρον), meaning "measure" [293, 299]. Together, they form a word that literally translates to "common measure" or "agreement in dimensions". In classical Greece, this concept was not just a mathematical abstraction but a fundamental principle of beauty and order, representing a harmonious and pleasing relationship between the various parts of a whole, whether in sculpture, architecture, or the cosmos itself [300, 301].

From Greece, the word journeyed into *Latin* as "symmetria", maintaining its form and meaning [302]. It was later adopted into *French* as "symétrie" during the 16$^{\text{th}}$ century, from which it was borrowed into English in the mid-1500s [296]. Initially, it retained its broader, classical sense of "due proportion" or a "harmonic arrangement", a meaning that was especially influential during the Renaissance among artists and architects who sought to emulate classical ideals of balance and form [296].

Over time, the meaning of "symmetry" began to evolve toward a more specific, scientific definition [296]. By the 17$^{\text{th}}$ and 18$^{\text{th}}$ centuries, it was increasingly used to describe the geometric concept of an object having two halves that are mirror images of each other, a notion known as *bilateral symmetry* [296]. This definition became particularly important in the developing fields of biology and natural history [296]. By the 19$^{\text{th}}$ and 20$^{\text{th}}$ centuries, the concept was fully formalized within mathematics and physics [300, 301]. In this modern context, symmetry describes the property of an object or system remaining unchanged (invariant) under specific transformations such as reflection, rotation, or translation, making it a cornerstone principle in fields ranging from crystallography to particle physics [300, 301].

The Sanskrit prefix *para-* (पर) points to a rich philosophical concept of transcendence rooted in the simple physical act of crossing a boundary. It descends from the Proto-Indo-European root *per-*, which meant "through, across, or beyond" [81, 292]. This ancient heritage is preserved in its direct cognates, such as Greek *pára* (παρά "beside, beyond"), and Latin *per* ("through") [293, 299, 81]. In Sanskrit, this idea of "crossing over" was elevated from the physical to the metaphysical, giving *para* its meaning of "other", "beyond", and ultimately "transcendent" [298]. This deeper sense is captured in key philosophical terms like *pāramitā* ("perfection", literally "gone to the other shore") and *paramārtha* ("ultimate truth") [298].

The prefix *holo-* is a direct borrowing from Ancient Greek, chosen for its powerful and precise meaning of integrated wholeness. Its use in modern scientific and philosophical terms like "hologram", "holistic", and the proposed "holo-state" is a deliberate invocation of an ancient concept: the idea of a system that is complete, entire, and more than the mere sum of its parts. This prefix signals a departure from a purely analytic or reductionist view, pointing instead to a reality where the identity and nature of the whole are irreducibly primary.

The term's lineage begins with the Ancient Greek word *ὅλος (hólos)*, which means "whole", "entire", "complete", or "total" [303]. In Greek thought, *hólos* was not just a quantitative measure of all the parts, but a qualitative descriptor of an integrated, organic unity. Aristotle, for instance, famously argued that a whole is something over and above its parts, possessing properties and a nature that cannot be understood by studying its components in isolation [73]. The word traces back to the Proto-Indo-European root *solh₂-*, meaning "whole" or "intact", which also gave rise to the Latin word *solidus* (solid) and the Sanskrit word *śarva* (सर्व, "all, whole, entire") [81]. This deep, shared linguistic ancestry reveals a foundational human intuition for the concept of an inviolable, complete entity.

The modern power of the prefix was significantly amplified by the invention of the *hologram*, a term coined by Dennis Gabor in 1949 [304, 305]. A hologram is a recording of a light field that exhibits a remarkable property: each part of the recording contains information about the entire three-dimensional image [306, 307, 308]. This physical manifestation of "the whole in every part" provided a powerful scientific metaphor for interconnectedness [309]. It transformed the ancient philosophical concept of *hólos* into a tangible principle, demonstrating a new kind of order where the global structure is enfolded within every local region [309].

The use of *holo-* in terms like *Quantum Holo-State* (Section 1.4) and *Holosymmetry* (Section 2.3) is therefore a direct appeal to this rich lineage. The *Holo-State*,then is not just a state that represents all the parts of the universe, but one that describes the universe as a single, indivisible quantum whole, where the information of the entire system is fundamentally entangled and non-local. Consequently, *Holosymmetry* alludes to a type of symmetry of this unbroken wholeness, a kind of symmetry that reflects the total, integrated nature of the Holo-State, a principle of invariance that is a property of the entire cosmic system, not just its isolated components.

1.3 The Primordial Quantum Singularity

The Big Bang, Singularities, and Cosmic Fates

The **Big Bang theory** is our leading framework for understanding the early universe. It describes how, from an extremely hot and dense state approximately 13.8 billion years ago, spacetime expanded and cooled, allowing for the formation of matter, radiation, and eventually the large-scale structures we observe today. The theory is supported by robust observational pillars, including the systematic redshifts of distant galaxies and the relic **cosmic microwave background**—a nearly uniform afterglow from that hot, early phase. These observations, combined with precise parameter fits from galaxy surveys and CMB data, provide a consistent cosmological model [310, 311]. When this classical description from General Relativity (GR) is traced backward in time, the expanding solution reaches a boundary where the model

can no longer be extended, indicating an "initial singularity" [312]. However, this is best understood not as a literal point of infinite density, but as a limit of the classical theory itself, signaling that a more fundamental theory of quantum gravity is required to describe the universe's earliest moments [240, 7, 8, 3, 12].

A possible, though now disfavored, fate for the universe is the **Big Crunch**, which is essentially the time-reverse of the Big Bang. In this scenario, the mutual gravitational attraction of all matter in the cosmos would eventually halt the expansion and cause the universe to recontract, growing hotter and denser until it collapses into a terminal singularity. Classically, this is a perfectly consistent fate within GR, provided the universe contains the right amount of energy and matter [7]. However, pivotal observations in the late 1990s revealed that the cosmic expansion is, in fact, **accelerating** [134, 135]. This acceleration strongly suggests the presence of a "dark energy" component with negative effective pressure, a dynamic that makes a future recollapse highly unlikely [313]. Instead, the long-term evolution of our universe appears to be heading toward a "Big Freeze"—an ever colder, more diffuse, and emptier cosmos [314, 315].

A **black hole** is another consequence of gravity predicted by GR, defined as a region of spacetime from which nothing, not even light, can escape. These objects form in nature through the complete gravitational collapse of sufficiently massive objects and are described by solutions in GR that feature an **event horizon**—the point of no return [7, 316, 317]. Within this horizon, continued collapse leads to an inner region where classical GR predicts its own breakdown in the form of a singularity [240, 312]. For a non-rotating (Schwarzschild) black hole, this singularity is often depicted as a point, whereas for a rotating (Kerr) black hole, the theory predicts a **ring singularity** [318]. In realistic scenarios, this singularity is thought to be hidden from outside observers by the event horizon, a principle known as cosmic censorship. A complete and physically realistic description of what happens at the very center of a black hole, however, is expected to require a full theory of quantum gravity [7, 8, 3].

What a Singularity Means in General Relativity

In general relativity, a "singularity" is not a literal place where physics "begins" or "ends," but a failure of the spacetime model: *geodesic incompleteness*, i.e., the existence of timelike or null geodesics that cannot be extended to arbitrarily large values of their affine parameters. In many—but not all—cases this accompanies the blow-up of curvature invariants such as the Kretschmann scalar $K = R_{abcd}R^{abcd}$ [7, 240, 146].

The focusing mechanism behind many singularity results is captured by *Raychaudhuri's equation* for a timelike geodesic congruence with 4-velocity u^a, expansion θ, shear σ_{ab}, and vorticity ω_{ab}:

$$\frac{d\theta}{d\tau} = -\frac{1}{3}\theta^2 - \sigma_{ab}\sigma^{ab} + \omega_{ab}\omega^{ab} - R_{ab}u^a u^b.$$

Assuming vanishing vorticity ($\omega_{ab} = 0$) and appropriate energy conditions (e.g., strong or null), the congruence inevitably *focuses* so that $\theta \to -\infty$ in finite proper time, leading to caustic formation. When combined with global geometric inputs (e.g., trapped surfaces), this focusing yields *geodesic incompleteness* via the Penrose–Hawking singularity theorems [7, 240, 316, 312].

Big Bang: did it "emerge from a singularity"?

In homogeneous/isotropic cosmology Friedmann–Lemaître–Robertson–Walker (FLRW),

$$ds^2 = -c^2dt^2 + a^2(t)\,\gamma_{ij}dx^i dx^j, \qquad H^2 = \left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G}{3}\rho - \frac{kc^2}{a^2} + \frac{\Lambda c^2}{3},$$

$$\frac{\ddot{a}}{a} = -\frac{4\pi G}{3}\left(\rho + \frac{3p}{c^2}\right) + \frac{\Lambda c^2}{3}.$$

For standard matter/radiation ($\rho > 0$, $p \geq 0$, and not-too-large Λ), evolving backward drives $a(t) \to 0$ in finite proper time; typical densities and curvature scalars diverge in the classical model. That "initial singularity" is *not a place in space* but a *past boundary* of the classical solution. In GR the mathematically precise statement is *geodesic incompleteness*: the FLRW solution cannot be extended past that boundary within the classical theory [240, 7, 144, 319].

Two rigorous points often missed:

1. The classic singularity theorems establish *incompleteness* under general conditions (energy conditions, trapped sets), not necessarily a smooth point where curvature "blows up." [240, 7]

2. *Inflation does not generically evade past-incompleteness*: many inflating spacetimes are still past-incomplete (Borde–Guth–Vilenkin) [320]

What happens "before" the classical boundary is a *quantum-gravity* question. Competing proposals include loop-quantum-cosmology bounces, [228, 321] ekpyrotic/cyclic scenarios, [322, 323] Penrose's conformal cyclic cosmology, [227] asymptotic safety, [324] string-gas cosmology, [325] and no-boundary initial conditions [51]. There is *no consensus* yet; current observations—especially CMB and large-scale structure—are well fit by ΛCDM with an inflationary early phase and show no decisive deviations that fix the pre-inflationary completion [150, 326, 327, 319].

Big Crunch: time-reversed Big Bang?

A **Big Crunch** is a future singularity in which the scale factor recontracts to $a(t) \to 0$ in finite proper time. In the classical $\Lambda = 0$ setting, closed universes ($k = +1$, $\Omega_{\text{tot}} > 1$) naturally recollapse; more generally, the fate hinges on the energy content and its effective equation of state for $a(t)$ [7, 144].

1. *Positive, nearly constant* Λ leads to asymptotic de Sitter expansion—eternal acceleration and no Crunch [314, 315].

2. *Negative* Λ or evolving dark energy that becomes effectively attractive can trigger turnaround and recollapse [144, 313].

3. Other exotic fates exist (e.g., *Big Rip* if $w < -1$) [313].

Empirically, late-1990s supernova observations established that the expansion is *accelerating*, consistent with dark energy close to $w \approx -1$, which disfavors a Crunch under current conditions; precision CMB and large-scale structure results reinforce this picture [134, 135, 150, 313].

Black holes and their singularities

For a Schwarzschild (non-rotating, uncharged) black hole, the surface $r = 2GM/c^2$ is an *event horizon* that is regular—its apparent pathology in Schwarzschild t is a coordinate artifact—while the interior, in the classical solution, terminates at $r = 0$, where curvature invariants (e.g., the Kretschmann scalar) diverge [7, 316]. The $r = 0$ singularity is *spacelike*, and any infaller reaches it in *finite proper time* of order GM/c^3 after crossing the horizon [7, 316].

For rotating (Kerr) or charged (Reissner–Nordström) solutions, the maximal analytic extension includes an inner (Cauchy) horizon and, in Kerr, a *ring singularity*; the inner horizon is widely expected to be *unstable* (mass-inflation type blue-shifts), so the smooth interior of the ideal solution is unlikely to survive realistic collapse [318, 316]. Penrose's *weak cosmic censorship* conjecture asserts that physically formed singularities remain hidden behind horizons (no generic "naked" singularities); while unproven in full generality, it is supported in many settings [312, 7]. (For formation via stellar collapse and compact-object context, see classic treatments [328, 317].)

Information, evaporation, and singularity resolution

Semiclassically, black holes radiate thermally via quantum fields on curved spacetime—the Hawking effect—so an isolated black hole loses mass and *evaporates* over time [87, 12]. In classical GR, the interior *singularity* remains part of the spacetime all the way to the endpoint of evaporation, which sharpens the *information problem*: how can unitary quantum evolution be reconciled with apparently thermal, information-erasing Hawking radiation [329, 330, 86, 331, 332, 333, 334]

A complementary, quantitative way to pose the puzzle is via the *Page curve*: if evaporation is unitary, the entropy of the radiation should rise and then fall after the Page time. Modern formulations (Hayden–Preskill; islands/replica-wormholes) provide concrete mechanisms for recovering this unitary Page curve in toy models and semiclassical gravity [335, 138, 336, 139, 337].

Candidate *resolutions* often align with mechanisms that also *tame the singularity*:

1. *Quantum-geometry replacements.* In loop-quantum-gravity–inspired models, strong-curvature interiors can be replaced by non-singular quantum phases (e.g., "Planck-star" or bounce scenarios), turning the would-be singular endpoint into a transition [42, 338, 339].

2. *String-theoretic microstate geometries / fuzzballs.* Black-hole microstates can be realized as horizon-sized, non-singular configurations, eliminating the need for a traditional interior singularity [340].

3. *Asymptotic safety / effective corrections.* If gravity flows to a nontrivial UV fixed point, high-curvature growth of invariants can be softened, potentially averting singular behavior within an effective description [341].

4. *Complementarity, state-dependence, and islands.* Black-hole complementarity and related interior reconstructions preserve exterior unitarity without accessible paradoxes

for any single observer; island/replica-wormhole methods reproduce the unitary entropy curve while leaving the deep interior to full quantum gravity [342, 343, 231, 139, 337].

What observations can test this? We probe the exterior, not the singular interior: precision measurements of quasinormal-mode *ringdowns* in gravitational waves and *horizon-scale imaging* constrain deviations from the classical exterior metrics. Direct access to the singularity is screened by the horizon [344, 345, 346, 347, 348].

Comparing the Singularities

In classical general relativity a "singularity" is best understood as *geodesic incompleteness*—a boundary of the spacetime model where classical evolution cannot be extended—often, though not invariably, accompanied by the blow-up of curvature invariants. On this definition, the *Big Bang* of FLRW cosmology is a *past boundary* of the classical solution rather than a location "in" space; it marks the point where GR ceases to be predictive and a quantum-gravitational description must supply initial data or a replacement dynamics [240, 7, 8, 3, 144, 319].

By contrast, a *black hole singularity* is an *interior* end-state of classical collapse lying to the *future* of any infalling observer. The event horizon of a Schwarzschild black hole is regular (its coordinate pathology is removable), but the classical interior terminates at a spacelike $r = 0$ singularity reached in finite proper time; rotating (Kerr) solutions admit a ring singularity in their maximal analytic extensions. In realistic collapse, the smooth inner structure of ideal stationary solutions is expected to be unstable, and the conjecture of *weak cosmic censorship* asserts that any singularities formed are hidden behind horizons [7, 316, 318, 312].

A third possibility, the *Big Crunch*, is a *future* singularity in recollapsing cosmologies (e.g., closed models with suitable energy content). Present evidence—cosmic acceleration from Type Ia supernovae and precision CMB/large-scale-structure constraints—is consistent with a nearly constant dark-energy component ($w \approx -1$), which disfavors recollapse under current conditions, though alternative late-time dynamics could alter the ultimate fate [134, 135, 150, 144].

In short: singularities in GR signal the *limits of the classical theory.* The Big Bang is a past boundary of cosmological evolution; black-hole singularities are future interior endpoints cloaked by horizons; and a Big Crunch, while classically allowed, is observationally disfavored today. In each case, it is widely expected that a quantum-gravitational completion will resolve the classical pathology without sacrificing unitarity or causality [240, 7, 8, 3].

From Classical Singularities and Qubit to the Primordial Quantum Singularity. In classical general relativity, a "singularity" marks *geodesic incompleteness*—a boundary of the spacetime model rather than a place in space; the Big Bang of FLRW cosmology is precisely such a *past boundary* of the classical solution, while black-hole interiors terminate at future, horizon-cloaked endpoints [240, 7, 144, 319]. Within the IQR framework, this role of a singularity—as the *limit of a description*—is recast as a *design principle* for the elementary quantum unit itself. The conventional *qubit*, a state in a fixed two-dimensional Hilbert space, is too impoverished to seed spacetime and matter as emergent structures; it presupposes kinematics and an inner product rather than generating them.

The *Primordial Quantum Singularity (PQS)* is therefore introduced as the *replacement for the qubit*: an *infinitesimal quantum neighborhood* equipped with the relational operator

content needed to *generate* both kinematics and dynamics. A PQS is not a just a state vector or a tiny spatial region; it is a locally instantiated operator domain whose relational channels, evaluated in the global Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$, produce the emergent Hilbert structure and the chronogeometric expectations that we interpret as spacetime and fields. In this sense, the PQS is the *elementary grain of reality* and the *local generator* of physical law, unifying "information" and "substrate" in a single construct.

Viewed against the classical narrative, the PQS plays the role of a *point of origin*—not as a curvature blow-up, but as a *foundational origin of distinguishability* from which geometry, matter, and causal order crystallize. Where the classical Big Bang is a past boundary beyond which GR cannot be extended [240, 7], the PQS supplies the *pre-geometric* data and lawful channels from which that boundary and its subsequent FLRW evolution can be derived as an emergent, coarse-grained phase. Thus the transition from qubit to PQS mirrors the transition from classical singularities to an operator-level genesis: the former assumes a background; the latter *produces* one.

Each PQS embodies the complete dual field structure $\hat{\mathbf{\Omega}}_x = {}_{\hat{\Phi}_x}\mathring{\mathbf{\Lambda}}_{x,\hat{\Theta}_x}$, where $\hat{\mathbf{\Phi}}_x$ and $\hat{\mathbf{\Theta}}_x$ are operator-valued fields and $\mathring{\mathbf{\Lambda}}_x$ encodes the foundational Fourfold Dialectic Algebra of Symmetry. This is not a point in the classical geometric sense, nor merely an open region within pre-existing space, but an irreducible singular unit of quantum structure whose properties are delineated entirely through relational constructs. The defining characteristics of an PQS—including its effective spatio-temporal extent—emerge from state-dependent structures governed by the emergent distance operator $\hat{\mathbf{d}}(x, x')$ (Section 4.16) and emergent time $t_{\text{em}}^{(\mathring{\mathbf{\Psi}})}(x, x')$ (Section 4.12), all contextualized by the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27).

This represents a profound paradigm shift: observable phenomena such as macroscopic spacetime geometry, causal flow, and matter content arise only from the relational network between distinct PQSs, never from within a single, isolated one. The PQS thus marks the precise threshold between the unstructured nature of the foundational singularity and the structured nature of relational emergence—the quantum seed from which space, time, fields, and causality all emerge relationally.

Definition: The Primordial Quantum Singularity

Definition 1.25 (Primordial Quantum Singularity $\mathfrak{B}_{\vec{r}}$ and its Quantum Holo-State)**.** Let $\mathcal{C}_d \subset \mathbb{R}^d$ be a smooth, differentiable base manifold, interpreted as the *Foundational Singularity Continuum* whose points $\vec{r}$ are primordial loci, or seeds, denoted $\hat{\Omega}_{\vec{r}}$ (Definition 4.617). To each such locus $\vec{r} \in \mathcal{C}_d$, we assign a *Quantum Primordial Singularity* $\mathfrak{B}_{\vec{r}}$. The PQS is not just a "point", but is *defined by* the instantiation of the complete primordial duality structure at this locus:

$$\boxed{\mathfrak{B}_{\vec{r}} := \hat{\mathbf{\Omega}}_{\vec{r}} := {}_{\hat{\Phi}_{\vec{r}}}\mathring{\mathbf{\Lambda}}_{\vec{r},\hat{\Theta}_{\vec{r}}}} \tag{1.3}$$

where $\hat{\mathbf{\Phi}}_{\vec{r}}$, $\hat{\mathbf{\Theta}}_{\vec{r}}$, and $\mathring{\mathbf{\Lambda}}_{\vec{r}}$ are the local instantiations of the Gaiamiti field (Definition 6.118), Tantrakyma field (Definition 6.142), and the algebra of duality, respectively. This operator-valued entity $\mathfrak{B}_{\vec{r}}$, representing an elementary quantum singularity, is intrinsically and fundamentally described by the *Quantum Holo-State*, conceptually denoted $\mathring{\mathbf{\Psi}}$ and represented

by the state vector $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27), which encapsulates its complete quantum nature. Each PQS $\mathfrak{B}_{\vec{r}}$ is thus a fully structured, operator-valued singularity—a self-contained, dual quantum locus whose definitive quantum state is $|\mathring{\mathbf{\Psi}}\rangle$. The quantum singularity will be employed to replace the conventional Bloch-sphere qubit (which is a state vector in a fixed $\mathbb{C}^2$ space), with a dynamic, higher-order, field-embedded, and duality-governed object that serves as the source of emergent physical reality, and hence, the apex of causality (Section 5.4.6).

Motivations: The Emergent Quantum Configuration Space

The Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27), realized through the GNS construction (Definition 1.34), generates the total emergent Hilbert space $\mathcal{H}_{\text{em}}$ from the algebra of observables. Yet this global construction leaves a fundamental question unanswered: how does this unified quantum state manifest the multiplicity of distinguishable entities we observe in physical reality? The answer lies in recognizing that while the state is universal, the operator structures it governs are inherently local—each Primordial Quantum Singularity $\mathfrak{B}_{\vec{r}}$ in the $\hat{\Omega}$-Continuum carries its own field operators $\mathring{\mathbf{\Lambda}}_{\hat{\Phi}_{\vec{r}},\hat{\Theta}_{\vec{r}}}$ (Definition 1.25). This tension between global state and local operators necessitates an intermediate structure: the quantum configuration space.

The emergence of distinguishable loci from the primordial continuum follows a principle of relational crystallization. Within the $\hat{\Omega}$-Continuum $\mathcal{C}_d$ (Definition 4.617), each point hosts an PQS—a domain where all relational measures vanish identically. These are regions of perfect quantum indistinguishability, where the operator-valued distances $\hat{\mathbf{d}}(x, x') = \mathbf{0}$ and emergent proper times $t_{\text{em}}^{(\mathring{\mathbf{\Psi}})}(x, x') = 0$ for all points within the same PQS (eq. (1.5)). Physical space emerges only when we identify which collections of points can be distinguished by quantum-relational measurements. This motivates the construction of the quantum configuration space $\mathcal{X}_q$ as a quotient of the continuum, where each point represents a relationally defined locus of distinguishability—an equivalence class of indistinguishable PQS constituents. This construction is rigorously developed in Section 4.19.3, with the emergence formally established in Proposition 4.625.

Once crystallized, $\mathcal{X}_q$ serves as the organizational backbone for the emergent Hilbert structure described in Section 4.1. The total emergent Hilbert space $\mathcal{H}_{\text{em}}$ naturally organizes itself as a bundle over this configuration space (Definition 4.239), with each fiber $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ (Definition 4.273) representing the internal modal structure of the PQS at each relationally distinguished locus x. The inner products within these fibers are not imposed axiomatically but emerge through the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ (Definition 4.9), evaluated in the Quantum Holo-State (Definition 4.228 and eq. (4.85)). This creates a self-consistent structure where the global state determines local metrics, while the configuration space provides the arena for organizing these local structures into a coherent whole. In this framework, $\mathcal{X}_q$ is goes beyond where physics happens—it is the *first layer of emergent structure*, the relational scaffold upon which both quantum mechanics and spacetime geometry are built.

1.3.1 Coordinate Equivalence of the Primordial Quantum Singularity

Let $\varphi : \mathcal{C}_d \to \mathcal{X}_q$ be the diffeomorphic map (or quotient map, if $\mathcal{X}_q$ emerges via identification of indistinguishable points in $\mathcal{C}_d$ as established in Section 4.19.3) from the base manifold $\mathcal{C}_d$ to the emergent *quantum configuration space* $\mathcal{X}_q$. For every $\vec{r} \in \mathcal{C}_d$, its image is $x := \varphi(\vec{r}) \in \mathcal{X}_q$. We can then index the PQS by points in $\mathcal{X}_q$:

$$\boxed{\mathfrak{B}_{\vec{r}} = \mathfrak{B}_x := {}_{\hat{\Phi}_x}\overset{\circ}{\mathbf{\Lambda}}_{x,\hat{\Theta}_x}} \tag{1.4}$$

This signifies that the same fundamental quantum structure $\mathfrak{B}$, whose intrinsic state is $|\overset{\circ}{\mathbf{\Psi}}\rangle$, can be viewed from a pre-geometric perspective (labeled by $\vec{r} \in \mathcal{C}_d$) or a post-geometric, relational perspective (labeled by $x \in \mathcal{X}_q$). The internal structure ${}_{\hat{\Phi}}\overset{\circ}{\mathbf{\Lambda}}_{\hat{\Theta}}$ (generic form) is instantiated at x through the local field operator structures $\hat{\Phi}_x, \hat{\Theta}_x, \overset{\circ}{\mathbf{\Lambda}}_x$.

Interpretational Shift and Emergent Hilbert Spaces: This formulation marks a revolutionary departure from conventional quantum theory's foundational assumptions. The Quantum Primordial Singularity $\mathfrak{B}_x$—an operator-valued entity whose quantum essence is captured by the Quantum Holo-State $|\overset{\circ}{\mathbf{\Psi}}\rangle$—transcends and supplants the abstract qubit as the elementary building block of quantum reality. Where the qubit represents merely a two-level system residing in a pre-defined mathematical space, the PQS embodies a complete inversion of this conceptual hierarchy.

The PQS represents a profound ontological shift: it is not a state vector dwelling within some pre-ordained Hilbert space, but rather a *localized field-theoretic configuration*—an operator-valued singularity whose very quantum nature *is* $|\overset{\circ}{\mathbf{\Psi}}\rangle$ and which carries intrinsic operator-algebraic structure. This reverses the traditional hierarchy where states exist in spaces; here, the state itself generates the space. The PQS is simultaneously the quantum entity and the source of the mathematical structures needed to describe it, embodying a self-referential completeness absent in conventional formulations.

This new paradigm re-envisions the *modal Hilbert spaces*, exemplified by the two-dimensional space $\mathcal{H}_2^{(\mathfrak{B}_x)}$ encoding the Symmetry/Antisymmetry duality inherent in $\overset{\circ}{\mathbf{\Lambda}}_x$ (Definition 4.617 for the foundational context and Definition 4.273 for the modal construction), as *representational approximations* of the PQS's internal duality modes, a departure from treating them as fundamental structures. Whether realized through the GNS construction applied to local operator algebras—with $|\overset{\circ}{\mathbf{\Psi}}\rangle$ serving as the cyclic vector for the state functional $\omega^{\overset{\circ}{\mathbf{\Psi}}}$—or as effective descriptions under specific physical conditions, this emergence (eq. (4.85)) exemplifies the new paradigm where Hilbert spaces themselves become emergent phenomena rather than fixed mathematical stages. The mathematical structures we use to describe quantum mechanics are thus revealed as secondary, derived from the more fundamental operator-theoretic reality of the PQS continuum.

1.3.2 Defining Properties of the Primordial Quantum Singularity

The Primordial Quantum Singularity $\mathfrak{B}_x$ embodies a profound principle of quantum indistinguishability that lies at the heart of emergent geometry. Within the IQR, each singularity represents not just a point but a fundamental domain of relational opacity—a locus where the very measures that distinguish one configuration from another vanish identically. This defining characteristic is captured through the formal condition that for all configurations $x' \in \mathcal{X}_q$ belonging to the singularity $\mathfrak{B}_x$, the emergent relational measures yield null values when evaluated in the context of the Quantum Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$:

$$\boxed{\forall x' \in \mathfrak{B}_x : \quad \hat{\mathbf{d}}(x, x') = \mathbf{0} \quad \text{and} \quad t_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}(x, x') = 0.} \tag{1.5}$$

This twin condition reveals the deep unity between spatial and temporal indistinguishability at the quantum-singular scale. The vanishing of the operator-valued distance $\hat{\mathbf{d}}(x, x') = \mathbf{0}$ encompasses the simultaneous nullity of all three fundamental measures—correlational, vacuum-response, and spectral distances—signifying that no quantum-relational probe can differentiate between x and x'. The temporal counterpart, $t_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}(x, x') = 0$, emerges as a natural consequence, establishing that within the PQS, the flow of emergent proper time ceases to have operational meaning.

This principle of perfect quantum indistinguishability transforms our understanding of the fundamental scale. Within the conceptual boundary of a single $\mathfrak{B}_x$, the familiar everyday notions of "here" versus "there" and "now" versus "then" lose their operational significance (Section 4.16). The PQS thus represents a threshold phenomenon—a quantum domain where the relational structures that give rise to space, time, and causality have not yet crystallized from the pre-geometric substrate. It is precisely at the boundaries between distinct PQSs that distinguishability emerges, and with it, the entire apparatus of spacetime geometry unfolds from these infinitesimal seeds of relational structure.

Remark 1.26 (Relational Emergence from the Primordial Quantum Singularity $\mathfrak{B}_x$)**.** Consider a Primordial Quantum Singularity $\mathfrak{B}_x := {}_{\hat{\Phi}_x}\overset{\circ}{\boldsymbol{\Lambda}}_{x,\hat{\Theta}_x}$ (Definition 1.25) associated with configuration $x \in \mathcal{X}_q$ (Proposition 4.625). This entity embodies a profound principle: within its infinitesimal quantum domain, the relational measures that constitute observable physical reality have not yet emerged. For any configuration $x' \in \mathfrak{B}_x$, the fundamental relational structures—the operator-valued distance $\hat{\mathbf{d}}(x, x')$ (Section 4.16) and emergent proper time $t_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}(x, x')$ (Section 4.12)—yield null values relative to x (Definition 4.617).

This vanishing should not be misunderstood as "nothingness". Rather, $\mathfrak{B}_x$ represents a *domain of pure quantum potentiality*—a local quantum singularity where distinguishability has not yet crystallized, even though the complete dual field structure ${}_{\hat{\Phi}_x}\overset{\circ}{\boldsymbol{\Lambda}}_{x,\hat{\Theta}_x}$ remains fully present. Each PQS thus contains the potential for all physical phenomena through its operator-valued fields and duality algebra, yet this potential remains latent until brought into relation with other singularities. The quantum essence of this structure is encoded in the Quantum Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ (Definition 1.27), which provides the global coherence necessary for relational structures to emerge.

The framework's central insight is that observable reality—spacetime geometry, matter content, and dynamical evolution—emerges not from within these singular domains but through the relational fabric woven between them. Physical phenomena arise through the distinctions, correlations, and interactions established between distinct Primordial Quantum Singularities $\mathfrak{B}_x, \mathfrak{B}_{x'}, \ldots$ distributed across the configuration space $\mathcal{X}_q$. This represents a fundamental inversion of traditional physics: rather than objects existing in space and interacting through forces, the IQR posits that space, time, and forces themselves emerge from the coherent network of relations between these irreducible quantum nodes. Each singularity serves simultaneously as a boundary condition for emergence and a seed of potential structure, with reality crystallizing in the relational interstices between them.

1.4 The Quantum Holo-State

Definition 1.27 (The Quantum Holo-State $\mathring{\mathbf{\Psi}}$)**.** The *Quantum Holo-State*, denoted conceptually as $\mathring{\mathbf{\Psi}}$ and represented mathematically by the state vector $|\mathring{\mathbf{\Psi}}\rangle$, constitutes the singular quantum state that fundamentally characterizes every *Primordial Quantum Singularity* $\mathfrak{B}_x$ (Definition 1.25) in existence. Each PQS manifests as a localized expression of this universal state through its position-dependent operator structure $\mathfrak{B}_x \equiv \hat{\mathbf{\Omega}}_x := {}_{\hat{\Phi}_x}\mathring{\mathbf{\Lambda}}_{x,\hat{\Theta}_x}$, where the field operators $\hat{\Phi}_x$ and $\hat{\Theta}_x$ carry spatial indices while the underlying quantum state remains universal. This remarkable duality—universal state with localized operator manifestations—ensures that while all PQSs throughout the foundational $\hat{\Omega}$–Continuum (Definition 4.617) share the same intrinsic quantum essence, they maintain distinguishability through their position-dependent field structures.

The universality of $|\mathring{\mathbf{\Psi}}\rangle$ implies a profound unity: it simultaneously characterizes each individual singularity as a localized mode or aspect of itself, while also describing the coherent totality of the system they collectively form. This is not a contradiction but rather the essential feature that enables global quantum coherence while preserving local distinguishability—each PQS represents a particular "perspective" or "excitation" of the universal state, differentiated by its operator-valued coordinates in the emergent configuration space.

The state $|\mathring{\mathbf{\Psi}}\rangle$ transcends the conventional paradigm of states residing in pre-existing spaces; instead, it generates its own arena of existence through the total emergent Hilbert space $\mathcal{H}_{\text{em}}$ (Definition 4.287), actualized via the GNS construction (Definition 1.34). In a profound recursive foundation, the inner product structure of $\mathcal{H}_{\text{em}}$ itself emerges relationally from the very state it hosts, with $|\mathring{\mathbf{\Psi}}\rangle$ serving as both the architect and inhabitant of its mathematical home (as detailed in Definition 4.228 through eq. (4.85)).

Through its unique position as the quantum essence of every PQS, the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ bridges the microscopic and macroscopic realms—establishing both the local quantum mechanical framework and the global geometric structure. The following propositions formalize these foundational roles.

Proposition 1.28 (Role of $\mathring{\mathbf{\Psi}}$ in Defining Emergent Spacetime)**.** *The Quantum Holo-State* $|\mathring{\mathbf{\Psi}}\rangle$ *determines the emergent geometric and causal structures through the following relations:*

(i) The expectation-level metric tensor is given by $\bar{g}_{\mu\nu}(x) = \langle \overset{\circ}{\boldsymbol{\Psi}} | \hat{g}_{\mu\nu}(x) | \overset{\circ}{\boldsymbol{\Psi}} \rangle$ *(Definition 5.10), where* $\hat{g}_{\mu\nu}(x)$ *is the operator-valued metric tensor (Definition 5.1).*

(ii) The emergent proper time is defined as $t_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}(x, x')$ *(Definitions 5.17 and 5.22).*

(iii) For each PQS $\mathfrak{B}_x$ *(Definition 1.25), the relations* $\hat{\mathbf{d}}(x, x') = \mathbf{0}$ *and* $t_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}(x, x') = 0$ *hold for all* $x' \in \mathfrak{B}_x$ *(eq. (1.5)).*

Remark 1.29 (Physical Interpretation)**.** The Quantum Holo-State acts as the cosmic lens through which the operator-theoretic substrate projects itself into observable phenomena. This mathematical structure embodies three profound physical principles: (i) represents the birth of classical geometry from quantum expectation—the operator-valued metric is projected through $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ into the smooth fabric of spacetime; (ii) captures the crystallization of temporal structure from operator-valued phase relationships; (iii) establishes each PQS as a zone of perfect quantum indistinguishability where the universe has not yet instantiated relational distinguishability.

Proposition 1.30 (Role of $\overset{\circ}{\boldsymbol{\Psi}}$ in Defining Local Quantum Mechanical Structure)**.** *The Quantum Holo-State* $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ *determines the inner product structure of the emergent modal Hilbert spaces* $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ *(Definition 4.273) associated with each Primordial Quantum Singularity* $\mathfrak{B}_x$ *(Definition 1.25) through the relation:*

$$\langle \psi_1 | \psi_2 \rangle_{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}} := \lim_{x' \to x} \langle \overset{\circ}{\boldsymbol{\Psi}} | \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] | \overset{\circ}{\boldsymbol{\Psi}} \rangle \tag{1.6}$$

where $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]$ *is the Fourfold Inter-Modal Correlator of Primordial Quantum Singularities (Definitions 4.9 and 4.228 and eq. (4.85)).*

Remark 1.31 (Unification of Scales)**.** This proposition reveals how the Quantum Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ bridges the microscopic and macroscopic realms of the theory. While Proposition Proposition 1.28 established its role in determining the emergent spacetime manifold $\mathcal{M}_{\text{em}}^{(\overset{\circ}{\boldsymbol{\Psi}})}$ at the collective level, here we see its complementary function: defining the operational rules of quantum mechanics at the local level through the metric structure of individual modal Hilbert spaces.

Thus, $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ embodies the ultimate synthesis—it serves as the defining quantum context for both the "arena" (the emergent spacetime arising from the collective of PQSs) and the "actors" (the internal quantum modes of each PQS and their dynamics). This dual role establishes the Quantum Holo-State as the singular foundation from which both geometry and quantum mechanics emerge as complementary aspects of a unified relational reality.

1.4.1 Gelfand-Naimark-Segal Construction of the Quantum Holo-State

The Algebra of Observables

Definition 1.32 (The Algebra of Observables $\mathcal{A}(\mathcal{C}_d)$)**.** The *Algebra of Observables*, denoted $\mathcal{A}(\mathcal{C}_d)$, is the complete, background-independent mathematical structure that encodes the

totality of relational observables accessible within the Primordial Quantum Singularity and the Fourfold Algebra ontology. It is formally defined as the C^*-algebra generated by the fundamental operator fields associated with each Primordial Quantum Singularity across the foundational $\hat{\Omega}$–Continuum (Definition 4.617).

Specifically, for each locus $\vec{r} \in \mathcal{C}_d$, the following operator fields generate the algebra:

1. *Geometric Generators:* The Gaiamiti Field operators $\{\hat{\mathbf{\Phi}}_{\vec{r}}\}$, which encode the potential for relational geometry.
2. *Matter-Content Generators:* The Tantrakyma Field operators $\{\hat{\mathbf{\Theta}}_{\vec{r}}\}$, encoding internal "flavor" and matter-like excitations.
3. *Symmetry Generators:* The Duality Algebra operators $\{\hat{\mathbf{\Lambda}}_{\vec{r}}\}$, representing the foundational symmetries at each locus.

The C^*-algebra $\mathcal{A}(\mathcal{C}_d)$ is then the smallest norm-closed, involutive algebra (under the C^*-norm topology) that contains all finite linear combinations, products, and adjoints of these generators. This closure ensures that the algebra is a complete and self-contained description of the system's potential dynamics and relational structure, prior to the specification of a state or the emergence of a Hilbert space.

Remark 1.33 (Physical Interpretation)**.** This algebraic formulation represents a profound reordering of physical ontology. In conventional physics, one typically begins with a background structure—such as a manifold or Hilbert space—upon which fields or operators are defined. The Primordial Quantum Singularity and the Fourfold Algebra framework inverts this order. It posits that the abstract algebra of what can be measured—and how observables relate—is more fundamental than any underlying space.

1. *The Language of Reality:* The algebra $\mathcal{A}(\mathcal{C}_d)$ constitutes the complete "language" of the universe—its grammar and vocabulary of physical relations. It contains every possible statement that can be made about the system's geometric and matter content.
2. *Pre-Geometric Nature:* Crucially, this algebra exists *prior* to any notion of distance, time, or localization. It is a purely relational construct. The "distance" between two observables is not spatial but algebraic, encoded in their commutators and algebraic dependencies, not in any background manifold.

By defining physical reality in terms of this abstract algebra, the framework achieves fundamental background independence. The state functional $\omega^{\mathring{\mathbf{\Psi}}}$ then acts upon this algebra to select a single, dynamically coherent instantiation of physical reality, and the GNS construction provides the emergent stage—the Hilbert space—upon which this reality unfolds.

The Gelfand-Naimark-Segal Construction

Definition 1.34 (Gelfand–Naimark–Segal Construction of the Quantum Holo-State)**.** Let $\mathcal{A}$ be the (unital) C^*-algebra of emergent observables associated to the Quantum Holo-State (Section 1.4). Let $\omega^{\mathring{\mathbf{\Psi}}} : \mathcal{A} \to \mathbb{C}$ be the state functional singled out by the Holo-State, assumed

linear, positive, and normalized ($\omega^{\overset{\circ}{\mathbf{\Psi}}}(\mathbb{I}) = 1$). The GNS construction produces a cyclic $*$-representation

$$\Big(\pi_{\overset{\circ}{\mathbf{\Psi}}},\ \mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}},\ |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle\Big),$$

which we also denote by $\mathcal{H}_{\text{em}} := \mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}}$ (the *emergent* Hilbert space).

Canonical steps. Writing $\omega := \omega^{\overset{\circ}{\mathbf{\Psi}}}$, define:

1. **Null space.** $\mathcal{N}_\omega := \{A \in \mathcal{A} :\ \omega(A^\dagger A) = 0\}$ (a left ideal in $\mathcal{A}$).
2. **Pre-Hilbert space.** On the quotient $\mathcal{A}/\mathcal{N}_\omega$, set
$$\langle [A], [B] \rangle_\omega := \omega(A^\dagger B), \qquad [A] \in \mathcal{A}/\mathcal{N}_\omega,$$
and let $\mathcal{H}_\omega$ be its completion.
3. **Representation.** $\pi_\omega : \mathcal{A} \to \mathcal{B}(\mathcal{H}_\omega)$ by
$$\pi_\omega(A)[B] := [AB], \qquad A, B \in \mathcal{A},$$
which is a bounded $*$-representation.
4. **Cyclic vector.** $|\Omega_\omega\rangle := [\mathbb{I}] \in \mathcal{H}_\omega$; it is cyclic since $\overline{\pi_\omega(\mathcal{A})|\Omega_\omega\rangle} = \mathcal{H}_\omega$.

We *identify*

$$\mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}} \equiv \mathcal{H}_\omega \equiv \mathcal{H}_{\text{em}}, \quad \pi_{\overset{\circ}{\mathbf{\Psi}}} \equiv \pi_\omega, \quad |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle \equiv |\Omega_\omega\rangle,$$

and regard $|\overset{\circ}{\mathbf{\Psi}}\rangle$ (the ontological Holo-State symbol) as represented by the *cyclic vector* $|\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle$ in $\mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}}$.

State recovery and Born-valued truth. For all $A \in \mathcal{A}$,

$$\omega^{\overset{\circ}{\mathbf{\Psi}}}(A) = \langle \Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}} |\, \pi_{\overset{\circ}{\mathbf{\Psi}}}(A)\, |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle.$$

In particular, for any *effect* $E \in \mathcal{A}$ (with $0 \le E \le \mathbb{I}$), the Born-valued dialectic truth (Definition 1.18) is obtained either as an expectation in the cyclic GNS state,

$$v(E) \ = \ \omega^{\overset{\circ}{\mathbf{\Psi}}}(E) \ = \ \langle \Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}} |\, \pi_{\overset{\circ}{\mathbf{\Psi}}}(E)\, |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle,$$

or, more generally, for any normal preparation ρ on $\mathcal{H}_{\text{em}}$,

$$v(\rho; E) \ = \ \mathrm{Tr}\Big(\rho\, \pi_{\overset{\circ}{\mathbf{\Psi}}}(E)\Big).$$

Compatibility with the Fourfold Dialectic Algebra. Define the set of corner effects (Definitions 1.16 and 1.18)

$$\mathcal{E}_{\text{corner}} \ := \ \{\, P_T,\ P_A,\ P_{\text{para}},\ E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})} \,\}.$$

Their GNS images act on the emergent Hilbert space:

$$\pi_{\overset{\circ}{\mathbf{\Psi}}}\Big[\mathcal{E}_{\text{corner}}\Big] = \Big\{\, \pi_{\overset{\circ}{\mathbf{\Psi}}}(P_T),\ \pi_{\overset{\circ}{\mathbf{\Psi}}}(P_A),\ \pi_{\overset{\circ}{\mathbf{\Psi}}}(P_{\text{para}}),\ \pi_{\overset{\circ}{\mathbf{\Psi}}}(E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}) \,\Big\} \ \subset\ \mathcal{B}(\mathcal{H}_{\text{em}}).$$

Consequently, all Born-valued valuations defined at the logical layer are realized as standard quantum expectations on $\mathcal{H}_{\text{em}}$.

Uniqueness. The GNS triple is unique up to unitary equivalence: if $(\pi', \mathcal{H}', |\Omega'\rangle)$ is another cyclic representation with $\omega^{\mathring{\mathbf{\Psi}}}(A) = \langle\Omega'|\pi'(A)|\Omega'\rangle$ for all $A \in \mathcal{A}$, then there exists a unitary $U : \mathcal{H}_{\mathring{\mathbf{\Psi}}} \to \mathcal{H}'$ with $U\,\pi_{\mathring{\mathbf{\Psi}}}(A) = \pi'(A)\,U$ and $U|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle = |\Omega'\rangle$.

Remark 1.35 (Nonunital algebras)**.** If $\mathcal{A}$ is nonunital, replace $\mathbb{I}$ with the unit of the minimal unitization $\tilde{\mathcal{A}}$ in the quotient step; the construction and identifications above go through unchanged.

Remark 1.36 (Self-Generating Structure)**.** The GNS construction reveals a striking feature of the Quantum Holo-State: it *generates its own arena of existence*. The state functional $\omega^{\mathring{\mathbf{\Psi}}}$ fixes not only expectation values but the very Hilbert space $\mathcal{H}_{\mathring{\mathbf{\Psi}}}$ (also denoted $\mathcal{H}_{\text{em}}$) and its inner product. Explicitly, with the cyclic vector $|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle$ and representation $\pi_{\mathring{\mathbf{\Psi}}}$ produced by GNS, the inner product is defined by

$$\Big\langle \pi_{\mathring{\mathbf{\Psi}}}(A)\,|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle,\ \pi_{\mathring{\mathbf{\Psi}}}(B)\,|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle \Big\rangle_{\mathcal{H}_{\mathring{\mathbf{\Psi}}}} \;=\; \omega^{\mathring{\mathbf{\Psi}}}(A^\dagger B)\,, \qquad A, B \in \mathcal{A}.$$

Thus the ontological symbol $|\mathring{\mathbf{\Psi}}\rangle$ is *represented* by the cyclic vector $|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle$; the state functions simultaneously as the *seed* and the *standard of comparison* for the entire quantum–relational edifice—a precise embodiment of "the state defines the space that contains it."

Remark 1.37 (Physical Interpretation)**.** This construction is the mathematical expression of *background independence*. Where conventional quantum mechanics begins with a fixed Hilbert space—an immutable stage on which states live—our framework reverses the order: the foundational object is the operator algebra $\mathcal{A}(\mathcal{C}_d)$ encoding physical relations and observables, before any state space has crystallized. The state functional $\omega^{\mathring{\mathbf{\Psi}}}$ acts as a *selection principle* that carves out one coherent reality from the algebra's possibilities: by assigning expectations to all observables, it determines not just a state *within* a space, but the *space itself*. GNS is the engine that turns this abstract selection into concrete form, culminating in the emergent Hilbert space $\mathcal{H}_{\text{em}} = \mathcal{H}_{\mathring{\mathbf{\Psi}}}$—a bespoke arena sculpted by, and for, the state.

The identification $|\mathring{\mathbf{\Psi}}\rangle \equiv |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle$ therefore has genuine ontological bite: the universe's quantum state is not merely an inhabitant of a pre-given space; it is the *architect* of its own domain. When $\omega^{\mathring{\mathbf{\Psi}}}$ is extremal (i.e., a pure state on the C^*-algebra), the associated GNS representation is irreducible, capturing a cosmos governed by a single, indivisible quantum coherence rather than a mixture of alternatives. In this view, the quantum state and its mathematical arena emerge as inseparable aspects of a unified, self-determining whole—with Born-valued truth $\text{Tr}(\rho\,E)$ realized as ordinary expectations in the very space that the state brings into being.

1.4.2 The Fourfold Dialectic Algebra and the GNS Construction

The relationship between the *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16) and the *GNS Construction of the Quantum Holo-State* (Sections 1.4 and 1.4.1) is best read

Bridge: Fourfold Dialectic Algebra of Symmetry (Definition 1.16)

Corner (logic ↔ symmetry)	Ontological rep.	Quantum effect / projector	Born-valued truth	Measurement protocol
Thesis ↔ Symmetry	$\|\mathring{\mathbf{0}}\rangle$	$P_T = \|e_1\rangle\langle e_1\|$	$v_{\text{Thesis}}(\rho) = \text{Tr}(P_T\rho)$	Measure Σ_z on $\mathcal{H}_{(0,1)}$ basis $\{\|e_1\rangle, \|e_2\rangle\}$
Antithesis ↔ Antisymmetry	$\|\mathring{\mathbf{1}}\rangle$	$P_A = \|e_2\rangle\langle e_2\|$	$v_{\text{Antithesis}}(\rho) = \text{Tr}(P_A\rho)$	Measure Σ_z on $\mathcal{H}_{(0,1)}$ basis $\{\|e_1\rangle, \|e_2\rangle\}$
Synthesis ↔ Parasymmetry	$\frac{1}{\sqrt{2}}(\|\mathring{\mathbf{0}}\rangle + \|\mathring{\mathbf{1}}\rangle)$	P_{para}	$v_{\text{Synthesis}}(\rho) = \text{Tr}(P_{\text{para}}\rho)$	Measure Σ_x (para-axis) on $\mathcal{H}_{(0,1)}$
Holothesis ↔ Holosymmetry	$\mathring{\mathbf{0}}\mathring{\mathbf{\Lambda}}\mathring{\mathbf{1}}$	$E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$	$v_{\text{Holothesis}}(\rho) = \text{Tr}\big(E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}\rho\big)$	Control interferometer: prep $\|\mathbf{a}\rangle_c$, read $\|\mathbf{b}\rangle_c$

GNS / Emergent layer (Definition 1.34): $\mathcal{A}(\mathcal{C}_d)$ with state $\omega^{\mathring{\mathbf{\Psi}}}$ yields the cyclic triple $(\pi_{\mathring{\mathbf{\Psi}}}, \mathcal{H}_{\mathring{\mathbf{\Psi}}} = \mathcal{H}_{\text{em}}, |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle)$,

so that for any effect E: $\omega^{\mathring{\mathbf{\Psi}}}(E) = \langle\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}|\pi_{\mathring{\mathbf{\Psi}}}(E)|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle$, and for any preparation ρ on $\mathcal{H}_{\text{em}}$: $v(\rho; E) = \text{Tr}\big(\rho\,\pi_{\mathring{\mathbf{\Psi}}}(E)\big)$ (Definition 1.18).

Figure 1.2: From logic to lab: each corner's ontological label → realized effect → Born truth → measurement, grounded in the GNS/emergent layer.

as that between an axiomatic *blueprint* and its *actualization*. They are two facets of a single emergence process: the Dialectic Algebra specifies, *a priori*, the admissible modes of assertion—**Symmetry** (Thesis), **Antisymmetry** (Antithesis), **Parasymmetry** (Synthesis), **Holosymmetry** (Holothesis)—while the GNS mechanism turns these logical forms into concrete quantum tests and expectations inside an emergent Hilbert arena. The algebra of observables $\mathcal{A}(\mathcal{C}_d)$ supplies the complete operational vocabulary; the Quantum Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ (via its state functional $\omega^{\overset{\circ}{\boldsymbol{\Psi}}}$) selects a coherent world; and the GNS construction then *builds* the arena $\mathcal{H}_{\overset{\circ}{\boldsymbol{\Psi}}}$ (henceforth also denoted $\mathcal{H}_{\text{em}}$) in which the universe's quantum history unfolds. In short: the Dialectic provides the rules of construction, and GNS is the act of construction according to those rules.

The Hierarchical Architecture: From Logic to Reality The emergence proceeds through three tightly coupled levels.

1. Ontological Level: The Dialectic as Generative Logic Rooted in the *Principle of Duality*, the Fourfold Dialectic Algebra (Definition 1.16) is the system's generative logic rather than a descriptive overlay. From the primal polarity—**Symmetry** (Thesis) vs. **Antisymmetry** (Antithesis)—arises **Parasymmetry** (Synthesis) as their coherent organization, and **Holosymmetry** (Holothesis) as the meta-level that adjudicates or superposes entire evolutionary *histories* (Section 2.3). This fourfold structure is intrinsically present at every *Primordial Quantum Singularity* $\mathfrak{B}_x$ (Definition 1.25), providing the ontological anchors (ringed kets/meta-symbols) and the logical roles from which all subsequent physics—observables, dynamics, and patterns of entanglement—must emerge. Importantly, these ontological labels are *not* ordinary Hilbert vectors; they acquire quantum meaning only through a chosen realization (cf. Remark 1.22).

2. Algebraic Level: The Manifest Realization The Dialectic's "generative grammar" becomes a full mathematical language at the level of the *Algebra of Observables* $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32). Here the symmetry generators $\hat{\boldsymbol{\Lambda}}_{\vec{r}}$, together with the Gaiamiti and Tantrakyma operator fields (Definitions 6.118 and 6.142), provide the substrate on which the dialectical modes act. The corner propositions are represented by concrete *effects* in $\mathcal{A}(\mathcal{C}_d)$—e.g. P_T, P_A in the distinguished $(0,1)$-sector, the parasymmetric pair $P_{\text{para}}, P_{\text{antipara}}$, and the holosymmetric effect $E_{\text{Holo}}^{(\mathbf{a}\nrightarrow\mathbf{b})}$—so the Fourfold Dialectic is already *operational* at the algebraic level. Born-valued semantics (Definition 1.18) then assign to each corner a truth valuation $v(\rho; P) = \text{Tr}(P\rho)$, making "degree of warrant" a measurable probability.

3. Physical Emergence via GNS Construction Physical reality is obtained when the Holo-State $|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ acts as a selection principle through its state functional $\omega^{\overset{\circ}{\boldsymbol{\Psi}}}$ on $\mathcal{A}(\mathcal{C}_d)$, and the *Gelfand–Naimark–Segal* construction (Definition 1.34) produces the cyclic triple

$$\left(\pi_{\overset{\circ}{\boldsymbol{\Psi}}},\ \mathcal{H}_{\overset{\circ}{\boldsymbol{\Psi}}} = \mathcal{H}_{\text{em}},\ |\Omega_{\omega^{\overset{\circ}{\boldsymbol{\Psi}}}}\rangle\right).$$

In this representation, every algebraic effect E acts as the operator $\pi_{\overset{\circ}{\Psi}}(E)$ on $\mathcal{H}_{\text{em}}$, and the dialectic truth becomes an ordinary expectation:

$$\omega^{\overset{\circ}{\Psi}}(E) = \langle \Omega_{\omega^{\overset{\circ}{\Psi}}} | \pi_{\overset{\circ}{\Psi}}(E) | \Omega_{\omega^{\overset{\circ}{\Psi}}} \rangle, \qquad v(\rho; E) = \mathrm{Tr}\Big(\rho\, \pi_{\overset{\circ}{\Psi}}(E)\Big),$$

for the cyclic vector or any preparation ρ on $\mathcal{H}_{\text{em}}$. Thus the logical fourfold becomes a quartet of concrete, repeatable tests on the emergent space. When $\omega^{\overset{\circ}{\Psi}}$ is extremal, the GNS representation is irreducible, capturing a single, indivisible quantum coherence rather than a mixture.

The Essential Distinction: Grammar versus Language A linguistic analogy clarifies the roles. The *Fourfold Dialectic Algebra* (Definition 1.16) is the *generative grammar*: an *a priori* rulebook that determines which modal structures are syntactically admissible and why they must appear at all. The *Algebra of Observables* $\mathcal{A}(\mathcal{C}_d)$ is the *language*: the full lexicon of operators and relations (from the Gaiamiti/Tantrakyma fields to parasymmetric and holosymmetric composites) that say *what* can be physically stated and transformed. Finally, the *GNS construction* is the act of *uttering* a world: it gives these grammatical sentences a stage and a voice—$\mathcal{H}_{\text{em}}$ and $\pi_{\overset{\circ}{\Psi}}$—so that the four corners become measurable statements with Born-valued truth. In this sense, logic (grammar), algebra (language), and representation (utterance) are not separate add-ons but successive refinements of one unified emergence pipeline from ontology to experiment.

The Fundamental Trinity The complete picture resolves into a *trinity* of mutually entailed roles—**why**, **what**, and **how**—that together constitute reality in the IQR.

1. **Dialectic (Why).** The Fourfold Dialectic Algebra (Definition 1.16) states *why* the universe must exhibit its modal structure. Rooted in the Principle of Duality, it fixes the admissible corners (Thesis/Antithesis/Synthesis/Holothesis) and their interrelations as an *a priori* generative logic intrinsic to each PQS. These ontological labels are not yet Hilbert vectors; they are the blueprint from which realizations are drawn.

2. **Algebra (What).** The Algebra of Observables $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32) specifies *what* exists in precise mathematical form. It supplies the complete language of operators (including symmetry generators and the Gaiamiti/Tantrakyma fields) and instantiates the corners as effects $P_T, P_A, P_{\text{para}}, E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ with Born-valued truth $v(\rho; P) = \mathrm{Tr}(P\rho)$ (Definition 1.18). At this level the fourfold becomes *operational*: each corner corresponds to a concrete test.

3. **Holo-State via GNS (How).** The Quantum Holo-State $|\overset{\circ}{\Psi}\rangle$ (through its functional $\omega^{\overset{\circ}{\Psi}}$) determines *how* one coherent world is realized from the algebra's possibilities. The GNS construction (Definition 1.34) builds the emergent arena $\mathcal{H}_{\overset{\circ}{\Psi}} = \mathcal{H}_{\text{em}}$ with representation $\pi_{\overset{\circ}{\Psi}}$ and cyclic vector $|\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle$, so that all valuations become standard quantum expectations on the emergent space. In the extremal case, the representation is irreducible, reflecting a single, indivisible quantum coherence.

Taken together, *why* (Dialectic), *what* (Algebra), and *how* (Holo-State → GNS) form an unbroken pipeline from ontological principle to laboratory protocol. The Fourfold Dialectic and the Algebra of Observables are synchronized facets of the same entity, while the GNS construction provides its physical voice. In this sense, the universe is captured as a *self-generating* quantum state whose internal, dialectical logic projects itself—via algebra and representation—into the chronogeometric fabric we observe.

Level	**Structure**	**Function & Nature**
Ontological	Fourfold Dialectic Algebra (Definition 1.16)	Generative logic intrinsic to each PQS: specifies the four admissible modes (Thesis/Symmetry, Antithesis/Antisymmetry, Synthesis/Parasymmetry, Holothesis/Holosymmetry) and their roles as *corners*. Provides the *a priori* blueprint; ontological labels are pre-geometric (cf. Remark 1.22).
Algebraic	$\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32)	Concrete C^*-algebra of observables/relations (including symmetry generators and Gaiamiti/Tantrakyma fields). Realizes the corners as effects $P_T, P_A, P_{\text{para}}, E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ and endows them with Born-valued semantics $v(\rho; P) = \text{Tr}(P\rho)$ (Definition 1.18).
Physical	$(\pi_{\overset{\circ}{\mathbf{\Psi}}},\ \mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}} = \mathcal{H}_{\text{em}},\ \lvert\Omega_{\overset{\circ}{\omega^{\mathbf{\Psi}}}}\rangle)$ via GNS (Definition 1.34)	Emergent Hilbert arena and representation selected by the Quantum Holo-State. All corner valuations become ordinary expectations: $\overset{\circ}{\omega^{\mathbf{\Psi}}}(E) = \langle\Omega\lvert\pi_{\overset{\circ}{\mathbf{\Psi}}}(E)\rvert\Omega\rangle$, and more generally $v(\rho; E) = \text{Tr}(\rho\,\pi_{\overset{\circ}{\mathbf{\Psi}}}(E))$.

Table 1.1: Three-tiered hierarchy from generative logic to algebraic language to emergent physical representation in the IQR.

Chapter 2

The Fourfold Symmetry

2.1 Quantum Realizations of the Fourfold Symmetry

2.1.1 Realization of The Ontological Duality States

Definition 2.1 (Realization of the Ontological Duality Modes in $\mathbb{C}^4$)**.** Let $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} = \mathbb{C}^4$ denote the modal Hilbert space associated to a Primordial Quantum Singularity $\mathfrak{B}_x$. The fundamental ontological modes of the Fourfold Dialectic Algebra—Symmetry and Antisymmetry—are realized within this space as follows:

1. **Symmetry Mode (Thesis):**

$$|\mathring{\mathbf{0}}\rangle := |e_1\rangle := \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} \in \mathbb{C}^4, \tag{2.1}$$

2. **Antisymmetry Mode (Antithesis):**

$$|\mathring{\mathbf{1}}\rangle := |e_2\rangle := \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} \in \mathbb{C}^4, \tag{2.2}$$

These states span the fundamental $(0,1)$-subspace:

$$\mathcal{H}_{(0,1)} := \text{span}\,\{|e_1\rangle, |e_2\rangle\} \cong \mathbb{C}^2 \subset \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \tag{2.3}$$

3. **Generic Modal States:** Any modal state constrained to this sector at position x or

x' takes the form:

$$|\psi_1\rangle_x = c_{10}|\mathring{\mathbf{0}}\rangle_x + c_{11}|\mathring{\mathbf{1}}\rangle_x = \begin{pmatrix} c_{10} \\ c_{11} \\ 0 \\ 0 \end{pmatrix}_x ,$$

$$|\psi_2\rangle_{x'} = c_{20}|\mathring{\mathbf{0}}\rangle_{x'} + c_{21}|\mathring{\mathbf{1}}\rangle_{x'} = \begin{pmatrix} c_{20} \\ c_{21} \\ 0 \\ 0 \end{pmatrix}_{x'} ,$$

4. **Interpretation:** This realization faithfully embeds the ontological duality states within a conventional quantum mechanical Hilbert space, while preserving their dialectical meaning. All inter-modal correlator constructions restricted to the $(0,1)$-sector are now understood to act within $\mathbb{C}^2 \subset \mathbb{C}^4$.

Logical projectors and valuation Define $P_T := |e_1\rangle\langle e_1|$ and $P_A := |e_2\rangle\langle e_2|$ on $\mathcal{H}_{(0,1)}$. By Definition 1.18, $v_{\text{Thesis}}(\rho) = \text{Tr}(P_T\rho)$ and $v_{\text{Antithesis}}(\rho) = \text{Tr}(P_A\rho)$.

Quantum Realizations of the $(0,1)$-Sector Circuits

Definition 2.2 (Two-qubit embedding of the $(0,1)$-sector)**.** Let $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} = \mathbb{C}^4$ with computational basis $\{\,|e_1\rangle, |e_2\rangle, |e_3\rangle, |e_4\rangle\,\}$, and fix an identification with two qubits (q_1, q_0) via

$$|e_1\rangle \longmapsto |0\rangle_{q_1}|0\rangle_{q_0}, \qquad |e_2\rangle \longmapsto |0\rangle_{q_1}|1\rangle_{q_0}, \qquad |e_3\rangle \longmapsto |1\rangle_{q_1}|0\rangle_{q_0}, \qquad |e_4\rangle \longmapsto |1\rangle_{q_1}|1\rangle_{q_0}.$$

The ontological duality modes from Definition 2.1 satisfy

$$|\mathring{\mathbf{0}}\rangle \equiv |e_1\rangle \equiv |0\rangle_{q_1}|0\rangle_{q_0}, \qquad |\mathring{\mathbf{1}}\rangle \equiv |e_2\rangle \equiv |0\rangle_{q_1}|1\rangle_{q_0},$$

so that the $(0,1)$-sector is the subspace with $q_1 = |0\rangle$ and logical duality bit encoded in q_0.

Definition 2.3 (Circuit for the Symmetry mode (Thesis))**.** The Symmetry mode is $|\mathring{\mathbf{0}}\rangle \equiv |e_1\rangle$ (eq. (2.1)). Define the unitary

$$U_{\mathsf{Th}} := \mathbb{I}_{q_1} \otimes \mathbb{I}_{q_0}, \tag{2.4}$$

acting on the embedded $(0,1)$-sector. Starting from the initialized state $|0\rangle_{q_1}|0\rangle_{q_0}$, the circuit is the identity:

$$\begin{array}{l} |0\rangle_{q_1} \text{ ——} \\ |0\rangle_{q_0} \text{ ——} \end{array} \qquad \Longrightarrow \qquad |0\rangle_{q_1}|0\rangle_{q_0} \equiv |e_1\rangle \equiv |\mathring{\mathbf{0}}\rangle.$$

Definition 2.4 (Circuit for the Antisymmetry mode (Antithesis))**.** The Antisymmetry mode is $|\mathring{\mathbf{1}}\rangle \equiv |e_2\rangle$ (eq. (2.2)). Define the unitary that flips only the duality bit:

$$U_{\mathsf{AntiTh}} := \mathbb{I}_{q_1} \otimes X_{q_0}. \tag{2.5}$$

From the same initialization $|0\rangle_{q_1}|0\rangle_{q_0}$, the circuit is

$$|0\rangle_{q_1} \quad \text{———}$$
$$|0\rangle_{q_0} \quad \text{—}[X]\text{—} \qquad \Longrightarrow \qquad |0\rangle_{q_1}|1\rangle_{q_0} \equiv |e_2\rangle \equiv |\mathring{\mathbf{1}}\rangle.$$

Definition 2.5 (Projective tests matching $(0,1)$-sector effects)**.** Restricting to $q_1 = |0\rangle$, the Thesis/Antithesis effects (P_T, P_A) act as computational-Z tests on q_0:

$$P_T = |00\rangle\langle 00|\,, \qquad P_A = |01\rangle\langle 01|\,, \tag{2.6}$$

with standard Z-basis measurement on q_0 distinguishing the two modes.

Definition 2.6 (Synthesis of a generic $(0,1)$-state)**.** Any state $c_{10}|\mathring{\mathbf{0}}\rangle + c_{11}|\mathring{\mathbf{1}}\rangle$ is prepared by single-qubit rotations on q_0 while holding $q_1 = |0\rangle$:

$$|\psi\rangle \;=\; \Big(R_z(\phi)\,R_y(2\theta)\,|0\rangle\Big)_{q_0} \otimes |0\rangle_{q_1}\,, \quad \theta = \arccos|c_{10}|, \;\; \phi = \arg(c_{11}) - \arg(c_{10}). \tag{2.7}$$

A concrete circuit is

$$|0\rangle_{q_1} \quad \text{———————}$$
$$|0\rangle_{q_0} \quad \text{—}[R_y(2\theta)]\text{—}[R_z(\phi)]\text{—}$$

which reduces to Definitions 2.3 and 2.4 for $(\theta,\phi) = (0,0)$ and $(\frac{\pi}{2},0)$, respectively.

2.1.2 Local Involutive Duality Operators

Definition 2.7 (Local Involutive Duality Operator $D^{(\mathfrak{B}_x)}$)**.** Let $\mathfrak{B}_x$ be a Primordial Quantum Singularity located at point $x \in \mathcal{X}_q$, with associated modal Hilbert space $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$. The *local involutive duality operator*

$$D^{(\mathfrak{B}_x)} : \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \to \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$$

is the linear operator that acts nontrivially on the Symmetry–Antisymmetry sector as:

$$\boxed{D^{(\mathfrak{B}_x)} := |\mathring{\mathbf{0}}\rangle_x\langle\mathring{\mathbf{1}}|_x + |\mathring{\mathbf{1}}\rangle_x\langle\mathring{\mathbf{0}}|_x,} \tag{2.8}$$

and acts trivially (as the identity) on the orthogonal Parasymmetry and Holosymmetry subspaces.

This operator satisfies the following properties:

1. **Symmetry–Antisymmetry Interchange:**

$$D^{(\mathfrak{B}_x)}|\mathring{\mathbf{0}}\rangle_x = |\mathring{\mathbf{1}}\rangle_x, \qquad D^{(\mathfrak{B}_x)}|\mathring{\mathbf{1}}\rangle_x = |\mathring{\mathbf{0}}\rangle_x.$$

2. **Matrix Representation:**
   When restricted to the subspace span$\{|\mathring{\mathbf{0}}\rangle_x, |\mathring{\mathbf{1}}\rangle_x\}$, the operator is represented by the Pauli-X matrix:
$$D^{(\mathfrak{B}_x)} \cong \sigma_X = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

3. **Involution and Hermiticity:**
$$(D^{(\mathfrak{B}_x)})^\dagger = D^{(\mathfrak{B}_x)}, \qquad (D^{(\mathfrak{B}_x)})^2 = \mathbb{I}_{\text{mod}}^{(\mathfrak{B}_x)},$$
   where $\mathbb{I}_{\text{mod}}^{(\mathfrak{B}_x)}$ denotes the identity operator on $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$.

4. **Interpretation:**
   $D^{(\mathfrak{B}_x)}$ enacts a fundamental involutive transformation of internal quantum logic: it toggles the local dialectical configuration between Symmetry and Antisymmetry modes while preserving the higher-order Parasymmetric and Holosymmetric structures. It is the simplest nontrivial instance of a duality generator in the local modal algebra.

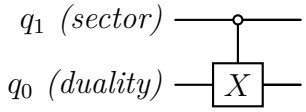
This operator provides the template for a hierarchy of generalized duality transformations—including parasymmetric reflection operators and holosymmetric coherence maps—that together generate the local action of the Fourfold Dialectic Algebra on modal state space. The full structure of this action will be developed in subsequent sections.

Quantum Circuit for the Local Involutive Duality Operator

Definition 2.8 (Embedding of $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} = \mathbb{C}^4$ into two qubits)**.** Identify the modal basis with two qubits (q_1, q_0) by
$$|e_1\rangle \mapsto |0\rangle_{q_1} |0\rangle_{q_0}, \quad |e_2\rangle \mapsto |0\rangle_{q_1} |1\rangle_{q_0}, \quad |e_3\rangle \mapsto |1\rangle_{q_1} |0\rangle_{q_0}, \quad |e_4\rangle \mapsto |1\rangle_{q_1} |1\rangle_{q_0}.$$
Then the $(0,1)$-sector is span$\{|00\rangle, |01\rangle\}$ with $|\mathring{\mathbf{0}}\rangle \equiv |e_1\rangle \equiv |00\rangle$ and $|\mathring{\mathbf{1}}\rangle \equiv |e_2\rangle \equiv |01\rangle$.

Definition 2.9 (Local involutive duality operator)**.** The operator in Definition 2.7 acts on the $(0,1)$-sector as
$$D^{(\mathfrak{B}_x)} = |\mathring{\mathbf{0}}\rangle_x\langle\mathring{\mathbf{1}}|_x + |\mathring{\mathbf{1}}\rangle_x\langle\mathring{\mathbf{0}}|_x, \tag{2.9}$$
and trivially on the orthogonal subspaces (Parasymmetry/Holosymmetry).

Proposition 2.10 (Circuit realization on two qubits (exact on $\mathbb{C}^4$))**.** *A unitary realizing eq. (2.9) on $\mathbb{C}^4$ and acting as the identity on the orthogonal subspaces is*
$$U_D = \big(|0\rangle\langle 0|\big)_{q_1} \otimes X_{q_0} + \big(|1\rangle\langle 1|\big)_{q_1} \otimes \mathbb{I}_{q_0}. \tag{2.10}$$
A circuit for eq. (2.10) is a zero-controlled X (open control) on q_1:



Its action on the basis is

$$|00\rangle \mapsto |01\rangle\,, \quad |01\rangle \mapsto |00\rangle\,, \quad |10\rangle \mapsto |10\rangle\,, \quad |11\rangle \mapsto |11\rangle\,,$$

i.e. it swaps $|e_1\rangle \leftrightarrow |e_2\rangle$ *and leaves* $|e_3\rangle, |e_4\rangle$ *invariant.*

Proof. Orthogonal projectors $|0\rangle\langle 0|$ and $|1\rangle\langle 1|$ on q_1 ensure block action. Hermiticity and involution follow from $X^\dagger = X$, $X^2 = \mathbb{I}$ and projector orthogonality:

$$U_D^\dagger = U_D, \qquad U_D^2 = |0\rangle\langle 0| \otimes X^2 + |1\rangle\langle 1| \otimes \mathbb{I} = \mathbb{I}_4.$$

On the $(0,1)$-sector ($q_1 = 0$) the restriction is X on q_0, matching eq. (2.8). □

Corollary 2.11 (Restricted one-qubit realization on $\mathcal{H}_{(0,1)} \cong \mathbb{C}^2$)**.** *If dynamics are confined to the* $(0,1)$*-sector (i.e.* q_1 *is fixed to* $|0\rangle$*), then*

$$D^{(\mathfrak{B}_x)} \;\cong\; \sigma_X \quad \textit{on the logical duality qubit } q_0, \tag{2.11}$$

with circuit

q_0 *(duality)* —[X]—

which realizes the swap $|\mathring{\mathbf{0}}\rangle \leftrightarrow |\mathring{\mathbf{1}}\rangle$.

2.1.3 Global Involutive Duality Operators

Definition 2.12 (Global Involutive Duality Operator $\hat{D}^{(n)}_{\mathrm{PQS}}$)**.** Let $\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ denote a configuration of n Primordial Quantum Singularities, each located at point $x_i \in \mathcal{X}_q$, and each equipped with its own emergent modal Hilbert space

$$\mathcal{H}^{(\mathfrak{B}_{x_i})}_{\mathrm{mod}} \cong \mathbb{C}^4,$$

as defined in Definition 4.273. The total modal Hilbert space of the configuration is the external tensor product:

$$\mathcal{H}^{(n)}_{\mathrm{PQS}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(\mathfrak{B}_{x_i})}_{\mathrm{mod}},$$

constructed fiberwise over the emergent configuration space $\mathcal{X}_q$ via the Hilbert bundle of dialectical modes (Definition 4.239).

We define the *global involutive duality operator* $\hat{D}^{(n)}_{\mathrm{PQS}}$ as the operator acting diagonally across this configuration, given by:

$$\boxed{\hat{D}^{(n)}_{\mathrm{PQS}} := \bigotimes_{i=1}^{n} D^{(\mathfrak{B}_{x_i})},} \tag{2.12}$$

where each $D^{(\mathfrak{B}_{x_i})}$ is the local involutive symmetry operator, acting on the Symmetry–Anti-symmetry sector of the modal fiber $\mathcal{H}^{(\mathfrak{B}_{x_i})}_{\mathrm{mod}}$.

This global operator satisfies:

$$\hat{D}^{(n)}_{\mathrm{PQS}}\left(\bigotimes_{i=1}^{n}|\psi\rangle_{x_i}\right)=\bigotimes_{i=1}^{n}\left(D^{(\mathfrak{B}_{x_i})}|\psi\rangle_{x_i}\right),$$

and thus implements a fiberwise involution across all singularities in the configuration. If each $|\psi\rangle_{x_i}\in\mathrm{span}\{|\mathring{\mathbf{0}}\rangle_{x_i},|\mathring{\mathbf{1}}\rangle_{x_i}\}$, then this action corresponds to a coherent exchange of Symmetry and Antisymmetry modes:

$$\hat{D}^{(n)}_{\mathrm{PQS}}\left(\bigotimes_{i=1}^{n}|\mathring{\mathbf{0}}\rangle_{x_i}\right)=\bigotimes_{i=1}^{n}|\mathring{\mathbf{1}}\rangle_{x_i},\quad\text{and vice versa.}$$

As such, $\hat{D}^{(n)}_{\mathrm{PQS}}$ defines a canonical involutive automorphism of the modal Hilbert bundle, encoding a globally synchronized transformation of internal duality structure. It characterizes a natural fiberwise symmetry of the emergent quantum geometry, acting as a discrete gauge transformation under the dialectical logic of Symmetry and Antisymmetry.

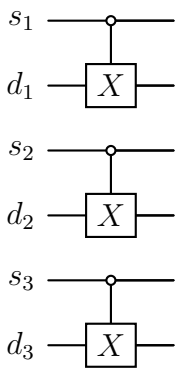
Definition 2.13 (Circuit for $\hat{D}^{(n)}_{\mathrm{PQS}}$ on the two–qubit-per-site embedding)**.** Let each site $i\in\{1,\dots,n\}$ be encoded by two qubits: a *sector* qubit s_i (pinning the $(0,1)$-sector by $|0\rangle$) and a *duality* qubit d_i (carrying $|\mathring{\mathbf{0}}\rangle\leftrightarrow|\mathring{\mathbf{1}}\rangle$). Define the site-local unitary

$$U_D^{(i)}\;=\;\Big(|0\rangle\langle 0|\Big)_{s_i}\otimes X_{d_i}\;+\;\Big(|1\rangle\langle 1|\Big)_{s_i}\otimes\mathbb{I}_{d_i},$$

so that the global operator is

$$\hat{D}^{(n)}_{\mathrm{PQS}}\;=\;\bigotimes_{i=1}^{n}U_D^{(i)},\quad\text{agreeing with } eq.\ (2.12).$$

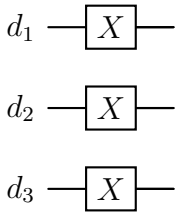
A circuit for $\hat{D}^{(n)}_{\mathrm{PQS}}$ applies, at each site i, an *open-control* (zero-controlled) X on d_i from s_i:



Remark 2.14 (Restriction to the $(0,1)$-sector at all sites)**.** If dynamics are confined to $\mathcal{H}_{(0,1)}^{\otimes n}$ (each s_i fixed to $|0\rangle$), then

$$\hat{D}^{(n)}_{\mathrm{PQS}}\;\cong\;\bigotimes_{i=1}^{n}X_{d_i}\;=\;X^{\otimes n}$$

on the logical n-qubit duality register $(d_1, \ldots, d_n)$, with circuit:



Remark 2.15 (Classification of the global involutive duality gate)**.** The operator defined in Definition 2.12 and eq. (2.12) is an *involutory, Hermitian, Clifford* gate. Concretely,

$$\hat{D}^{(n)}_{\mathrm{PQS}} = \bigotimes_{i=1}^{n} U_D^{(i)}, \quad U_D^{(i)} = \Big(|0\rangle\langle 0| \Big)_{s_i} \otimes X_{d_i} + \Big(|1\rangle\langle 1| \Big)_{s_i} \otimes \mathbb{I}_{d_i},$$

so each $U_D^{(i)}$ is an *open-controlled* X (zero-controlled-NOT) on the duality qubit d_i from the sector qubit s_i. Using the standard identity

$$U_D^{(i)} = (X_{s_i})\,\mathrm{CNOT}(s_i \to d_i)\,(X_{s_i}),$$

each factor is Clifford (hence so is the tensor product) and preserves the Pauli group under conjugation [287, 287, 349]. The gate is self-adjoint and an involution,

$$\Big(\hat{D}^{(n)}_{\mathrm{PQS}}\Big)^{\dagger} = \hat{D}^{(n)}_{\mathrm{PQS}}, \qquad \Big(\hat{D}^{(n)}_{\mathrm{PQS}}\Big)^{2} = \mathbb{I},$$

so it acts as a *reflection* (self-adjoint unitary) in the sense of elementary quantum mechanics [350]. On the embedded $(0,1)$-sector at all sites (i.e. each $s_i = |0\rangle$), the restriction reduces to the Pauli string

$$\hat{D}^{(n)}_{\mathrm{PQS}} \;\cong\; X_{d_1} \otimes \cdots \otimes X_{d_n} \;=\; X^{\otimes n},$$

which flips $|\mathring{\mathbf{0}}\rangle_{x_i} \leftrightarrow |\mathring{\mathbf{1}}\rangle_{x_i}$ at every site while leaving the orthogonal parasymmetry/holosymmetry sectors invariant [287, 351].

2.2 Parasymmetry: Quantum Realization of Synthesis

The Parasymmetric Modal Space

Definition 2.16 (Parasymmetric Modal Subspace)**.** Let $\mathfrak{B}_{x_i}$ be a Primordial Quantum Singularity with associated modal Hilbert space

$$\mathcal{H}^{(\mathfrak{B}_{x_i})}_{\mathrm{mod}} := \mathbb{C}^4.$$

Within this space, the *parasymmetric sector* is defined as the subspace spanned by the fundamental ontological duality modes:

$$\mathcal{H}^{(x_i)}_{(0,1)} := \mathrm{span}\left\{ |\mathring{\mathbf{0}}\rangle_{x_i},\ |\mathring{\mathbf{1}}\rangle_{x_i} \right\} \subset \mathbb{C}^4, \tag{2.13}$$

where the basis vectors are realized as:

$$|\overset{\circ}{\mathbf{0}}\rangle := \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad |\overset{\circ}{\mathbf{1}}\rangle := \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}.$$

Given a configuration of n Primordial Quantum Singularities $\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$, the *global parasymmetric modal subspace* is defined as the n-fold tensor product:

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}. \tag{2.14}$$

Hence, the parasymmetric sector has dimension:

$$\dim\left(\mathcal{H}^{(n)}_{\text{para}}\right) = 2^n.$$

2.2.1 Local Parasymmetric Projector of an PQS

Definition 2.17 (Parasymmetric Projector $P^{(\mathfrak{B}_x)}_{\text{para}}$)**.** Let $\mathfrak{B}_x$ be a Primordial Quantum Singularity with modal Hilbert space $\mathcal{H}^{(\mathfrak{B}_x)}_{\text{mod}} = \mathbb{C}^4$, and define the $(0,1)$-subspace as

$$\mathcal{H}_{(0,1)} := \text{span}\,\{|e_1\rangle, |e_2\rangle\} = \left\{ \begin{pmatrix} c_1 \\ c_2 \\ 0 \\ 0 \end{pmatrix} \;\middle|\; c_1, c_2 \in \mathbb{C} \right\}. \tag{2.15}$$

The *parasymmetric mode* is the equal-weighted coherent superposition:

$$|\overset{\circ}{\mathbf{0}} + \overset{\circ}{\mathbf{1}}\rangle_x := \frac{1}{\sqrt{2}}\left(|\overset{\circ}{\mathbf{0}}\rangle_x + |\overset{\circ}{\mathbf{1}}\rangle_x\right) = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}_x. \tag{2.16}$$

Then the *parasymmetric projector* is defined as:

$$\boxed{P^{(\mathfrak{B}_x)}_{\text{para}} := \left(|\overset{\circ}{\mathbf{0}} + \overset{\circ}{\mathbf{1}}\rangle_x\right)\left(\langle\overset{\circ}{\mathbf{0}} + \overset{\circ}{\mathbf{1}}|_x\right) = \frac{1}{2}\begin{pmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} \tag{2.17}$$

Properties

1. **Idempotency and Hermiticity**

$$(P_{\text{para}}^{(\mathfrak{B}_x)})^2 = P_{\text{para}}^{(\mathfrak{B}_x)}, \qquad (P_{\text{para}}^{(\mathfrak{B}_x)})^\dagger = P_{\text{para}}^{(\mathfrak{B}_x)}.$$

2. **Modal Projection**
   For any modal state $|\psi\rangle_x \in \mathcal{H}_{(0,1)}$, i.e.,

$$|\psi\rangle_x = \begin{pmatrix} c_0 \\ c_1 \\ 0 \\ 0 \end{pmatrix}_x ,$$

   we have:

$$P_{\text{para}}^{(\mathfrak{B}_x)}|\psi\rangle_x = \frac{1}{2}(c_0 + c_1) \cdot \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}_x . \tag{2.18}$$

3. **Interpretation**
   This operator isolates the *parasymmetric component* of any modal state in the $(0,1)$-sector, i.e., the projection along the direction of internal *dialectical synthesis* between Symmetry and Antisymmetry.
   It does *not* extend beyond the first two components of $\mathbb{C}^4$, since no formal realization has yet been provided for Holosymmetry or orthogonal parasymmetric bases. The parasymmetric state here is not orthogonal to both $|e_1\rangle$ and $|e_2\rangle$, but spans a *coherent subdirection* within that space.

The Parasymmetric Projector: An Operator of Synthesis The Parasymmetric Projector, denoted $P_{\text{para}}^{(\mathfrak{B}_x)}$, represents a profound mathematical realization of the dialectical principle of synthesis within the quantum mechanical framework. This operator selects a component of a quantum state as it also enacts a fundamental philosophical operation by isolating precisely that aspect of any state which embodies the coherent unification of the primal dialectical opposites. Formally, it projects onto the normalized superposition state:

$$|\mathring{\mathbf{0}} + \mathring{\mathbf{1}}\rangle_x := \frac{1}{\sqrt{2}} \left(|\mathring{\mathbf{0}}\rangle_x + |\mathring{\mathbf{1}}\rangle_x \right)$$

The normalization factor $1/\sqrt{2}$ ensures that this synthetic state maintains unit norm, thereby preserving quantum mechanical consistency while encoding the equal-weighted presence of both Thesis and Antithesis. As a "coherence filter," $P_{\text{para}}^{(\mathfrak{B}_x)}$ extracts from any arbitrary modal state its component of maximal coherent synthesis—that precise quantum amplitude which refuses the binary choice between existence and non-existence, instead embracing their simultaneous co-presence. Within the constraints of the primary $(0,1)$-subspace, this operator thus provides a concrete quantum mechanical instantiation of the third vertex of the dialectical tetralemma, demonstrating how abstract logical synthesis manifests as quantum superposition in the emergent modal Hilbert space of each Primordial Quantum Singularity.

2.2.2 The Local Anti-Parasymmetric Projector

Definition 2.18 (Anti-Parasymmetric Projector $P^{(\mathfrak{B}_x)}_{\text{antipara}}$)**.** Let the parasymmetric mode be defined within the $(0,1)$-subspace as

$$|\mathring{\mathbf{0}} + \mathring{\mathbf{1}}\rangle_x := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \end{pmatrix}_x . \tag{2.19}$$

We seek a state $|\psi^\perp\rangle \in \mathcal{H}_{(0,1)}$ such that

$$\langle \psi^\perp | \mathring{\mathbf{0}} + \mathring{\mathbf{1}} \rangle = 0.$$

This yields the *anti-parasymmetric mode*:

$$|\mathring{\mathbf{0}} - \mathring{\mathbf{1}}\rangle_x := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \\ 0 \\ 0 \end{pmatrix}_x , \tag{2.20}$$

which satisfies:

- $\|\cdot\| = 1$,
- orthogonality to $|\mathring{\mathbf{0}} + \mathring{\mathbf{1}}\rangle$,
- together with the parasymmetric mode, forms an orthonormal basis for $\mathcal{H}_{(0,1)}$.

The *anti-parasymmetric projector* is then defined as:

$$\boxed{P^{(\mathfrak{B}_x)}_{\text{antipara}} := |\mathring{\mathbf{0}} - \mathring{\mathbf{1}}\rangle_x \langle \mathring{\mathbf{0}} - \mathring{\mathbf{1}}|_x = \frac{1}{2} \begin{pmatrix} 1 & -1 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} \tag{2.21}$$

Properties

1. **Orthogonality to the Parasymmetric Projector**:

$$P^{(\mathfrak{B}_x)}_{\text{para}} \cdot P^{(\mathfrak{B}_x)}_{\text{antipara}} = 0.$$

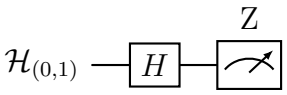
2. **Complementarity on the** $(0,1)$**-sector**:

$$P^{(\mathfrak{B}_x)}_{\text{para}} + P^{(\mathfrak{B}_x)}_{\text{antipara}} = |e_1\rangle\langle e_1| + |e_2\rangle\langle e_2| = P_T + P_A = P_{(0,1)} := \text{Proj}_{\mathcal{H}_{(0,1)}} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

(Here $|e_1\rangle, |e_2\rangle$ are the Symmetry/Antisymmetry basis; $P_T := |e_1\rangle\langle e_1|$, $P_A := |e_2\rangle\langle e_2|$.)

Interpretation. The anti-parasymmetric mode $|\mathring{\mathbf{0}} - \mathring{\mathbf{1}}\rangle$ captures the *modal dissonance*—the internal tension or conflict between Symmetry and Antisymmetry. Unlike the parasymmetric mode, which expresses dialectical synthesis, this state represents a logical stance of *non-coincidence* or *disjointed duality*. It remains fully internal to $\mathcal{H}_{(0,1)}$, and functions as a canonical orthogonal complement to the parasymmetric synthesis. ***Valuation Link*** $P^{(x)}_{\text{para}} \equiv P_S$ in Definition 1.18, so $v_{\text{Synthesis}}(\rho) = \text{Tr}\big(P^{(x)}_{\text{para}}\rho\big)$ (and analogously for the global $P^{(x_1\ldots x_n)}_{\text{para}}$).

Definition 2.19 (Local test for $P^{(\mathfrak{B}_x)}_{\text{para}}$ on $\mathcal{H}_{(0,1)}$)**.** Since $P^{(\mathfrak{B}_x)}_{\text{para}} = |+\rangle\langle+|$ with $|+\rangle := \frac{1}{\sqrt{2}}\big(|\mathring{\mathbf{0}}\rangle_x + |\mathring{\mathbf{1}}\rangle_x\big)$, a projective measurement in the X basis realizes the projector. Operationally: apply a Hadamard on the duality qubit and measure in Z; outcome 0 corresponds to projection by $P^{(\mathfrak{B}_x)}_{\text{para}}$, outcome 1 to $P^{(\mathfrak{B}_x)}_{\text{antipara}}$.



For an input state ρ on $\mathcal{H}_{(0,1)}$, $\Pr[0] = \text{Tr}\big(P^{(\mathfrak{B}_x)}_{\text{para}}\,\rho\big)$, $\Pr[1] = \text{Tr}\big(P^{(\mathfrak{B}_x)}_{\text{antipara}}\,\rho\big)$, with $P^{(\mathfrak{B}_x)}_{\text{para}} + P^{(\mathfrak{B}_x)}_{\text{antipara}} = P_{(0,1)}$.

Naimark flags. Ancilla bits (or registers) that record the outcome labels of a POVM via a Naimark dilation are called *Naimark flags* [287, 352, 353].

Binary case. Let E be an effect on a system $\mathcal{H}_S$ with $0 \le E \le I$. A Naimark dilation is a unitary U on $\mathcal{H}_S \otimes \mathcal{H}_a$ (with the ancilla initialised in $|0\rangle_a$) such that

$$U\big(|\psi\rangle \otimes |0\rangle_a\big) = \big(\sqrt{E}\,|\psi\rangle\big) \otimes |1\rangle_a + \big(\sqrt{I-E}\,|\psi\rangle\big) \otimes |0\rangle_a.$$

Measuring the ancilla in the Z basis "flags'' outcome 1 with probability $\langle\psi|E|\psi\rangle$ [287, 354]. If $E = P$ is a projector, then

$$U_P\big(|\psi\rangle \otimes |0\rangle_a\big) = (P|\psi\rangle) \otimes |1\rangle_a + \big((I-P)|\psi\rangle\big) \otimes |0\rangle_a,$$

so the ancilla acts as a flag qubit indicating membership in the subspace $\text{im}\,P$.

General POVM. Given a POVM $\{E_i\}_i$, there exists an ancilla with orthonormal basis $\{|i\rangle\}_i$ and an isometry $V : \mathcal{H}_S \to \mathcal{H}_S \otimes \mathcal{H}_a$ such that

$$E_i \;=\; V^\dagger\,(I \otimes |i\rangle\langle i|)\,V,$$

so that the ancilla basis states $|i\rangle$ serve as the Naimark flags [287, 352, 353, 355].

Circuit realisation (lifted parasymmetric projector). With the notation of the main text, $V^{(A)}_+$ (resp. $V^{(B)}_+$) rotates into a basis in which the desired projector is a computational-basis predicate; a multi-controlled X flips the ancilla a_A (resp. a_B) iff the data register lies in that projector's support, and uncomputing with V_+ restores the data. Concretely,

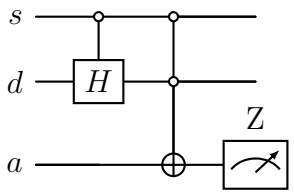
$$\big(V^{(A)}_+ \otimes I\big)\,CX\,\big(V^{(A)\dagger}_+ \otimes I\big) :\; |\psi\rangle\,|0\rangle_{a_A} \longmapsto \big(P_{\text{para}}|\psi\rangle\big)\,|1\rangle_{a_A} + \big((I - P_{\text{para}})|\psi\rangle\big)\,|0\rangle_{a_A}.$$

Measuring a_A or a_B gives a projective realisation of the corresponding effect (a *classical flag*); omitting the measurement yields a *coherent flag*, leaving the ancilla entangled with the system for downstream processing before optional uncomputation [287].

Definition 2.20 (Exact dilation of $P_{\text{para}}^{(\mathfrak{B}_x)}$ on $\mathbb{C}^4$)**.** Embed $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ into two qubits: a sector qubit s and a duality qubit d, with $|\mathring{\mathbf{0}}\rangle \equiv |0\rangle_s |0\rangle_d$, $|\mathring{\mathbf{1}}\rangle \equiv |0\rangle_s |1\rangle_d$. Introduce a flag ancilla a initialized in $|0\rangle_a$. Define the controlled-H that only acts on the $(0,1)$-sector,

$$U_{\text{prep}} := \Big(|0\rangle\langle 0| \Big)_s \otimes H_d \; + \; \Big(|1\rangle\langle 1| \Big)_s \otimes \mathbb{I}_d.$$

Then perform a two-control (both *open* / zero-controls) Toffoli that flips a iff s=0 and d=0 (i.e. after the H-rotation the state has $|0\rangle_d$):



Measuring a and postselecting on outcome 1 realizes the projector $P_{\text{para}}^{(\mathfrak{B}_x)} = |0\rangle\langle 0|_s \otimes |+\rangle\langle +|_d$ on the system:

$$\Pr[a{=}1] = \operatorname{Tr}\Big(\big[\, |0\rangle\langle 0|_s \otimes |+\rangle\langle +|_d \, \big] \, \rho \Big), \qquad \rho \text{ on } \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}.$$

By exchanging the open control on d (i.e. conditioning on d=1 after H), the complementary projector $P_{\text{antipara}}^{(\mathfrak{B}_x)}$ is obtained.

The Anti-Parasymmetric Projector: An Operator of Dissonance For every projection operator in quantum mechanics, mathematical completeness demands the existence of a complementary projection onto the orthogonal subspace. The Anti-Parasymmetric Projector, $P_{\text{antipara}}^{(\mathfrak{B}_x)}$, fulfills this role as the natural counterpart to the Parasymmetric Projector. This operator is constructed upon the mode orthogonal to the synthesis state within the $\mathcal{H}_{(0,1)}$ subspace, specifically projecting onto the anti-parasymmetric mode:

$$|\mathring{\mathbf{0}} - \mathring{\mathbf{1}}\rangle_x := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \\ 0 \\ 0 \end{pmatrix}_x$$

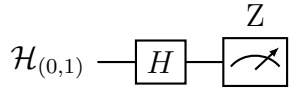
This state embodies the principle of perfect destructive interference between the Symmetry and Antisymmetry amplitudes, representing what the manuscript aptly characterizes as "modal dissonance" or "disjointed duality." The minus sign in the superposition ensures that the fundamental modes interfere destructively rather than constructively, yielding a state that captures opposition rather than synthesis. The corresponding projection operator takes the explicit matrix form:

$$P^{(\mathfrak{B}_x)}_{\text{antipara}} = \frac{1}{2}\begin{pmatrix} 1 & -1 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

The Interplay: A Complete Basis for Duality The profound elegance of this dual-projector construction manifests in the mathematical interplay between the Parasymmetric and Anti-Parasymmetric operators. These projectors satisfy two fundamental properties that illuminate their complementary nature. First, the orthogonality relation $P_{\text{para}} \cdot P_{\text{antipara}} = 0$ confirms that a quantum state cannot simultaneously embody perfect synthesis and perfect dissonance—these represent mutually exclusive modal configurations, and any measurement must yield one or the other. Second, the completeness relation $P_{\text{para}} + P_{\text{antipara}} = P_{(0,1)}$ establishes that these two operators span the entire $(0, 1)$-subspace, ensuring that any state within the fundamental duality sector admits a unique decomposition into components of pure synthesis and pure dissonance.

This construction effectively implements a change of basis within the modal Hilbert space, transitioning from the ontological "existence" basis of Symmetry, Antisymmetry to the phenomenologically richer "relationship" basis of Synthesis, Dissonance. This new basis proves particularly powerful for describing interactions and dynamics, as it directly quantifies the relational character—whether harmonious or dissonant—between the foundational dialectical modes. The mathematical framework thus captures the presence or absence of modal components and the quality of their mutual relationship within the quantum state.

Definition 2.21 (Local test for $P^{(\mathfrak{B}_x)}_{\text{antipara}}$ on $\mathcal{H}_{(0,1)}$)**.** Project onto $|-\rangle$ by rotating to the computational basis and measuring: apply H to the duality qubit and measure in Z; outcome 1 realizes $P^{(\mathfrak{B}_x)}_{\text{antipara}}$.



For input state ρ on $\mathcal{H}_{(0,1)}$,

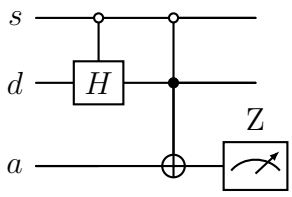
$$\Pr[1] = \operatorname{Tr}\Big(P^{(\mathfrak{B}_x)}_{\text{antipara}}\,\rho\Big), \qquad \Pr[0] = \operatorname{Tr}\Big(P^{(\mathfrak{B}_x)}_{\text{para}}\,\rho\Big),$$

with $P^{(\mathfrak{B}_x)}_{\text{para}} + P^{(\mathfrak{B}_x)}_{\text{antipara}} = P_{(0,1)}$.

Definition 2.22 (Exact dilation of $P^{(\mathfrak{B}_x)}_{\text{antipara}}$ on $\mathbb{C}^4$)**.** Embed $\mathcal{H}^{(\mathfrak{B}_x)}_{\text{mod}} \cong \mathbb{C}^4$ into sector s and duality d qubits with $|\mathring{\mathbf{0}}\rangle \equiv |0\rangle_s\,|0\rangle_d$, $|\mathring{\mathbf{1}}\rangle \equiv |0\rangle_s\,|1\rangle_d$, and introduce a flag ancilla a initialized in $|0\rangle_a$. First perform a *sector-conditioned* Hadamard on d,

$$U_{\text{prep}} := \Big(\,|0\rangle\langle 0|\,\Big)_s \otimes H_d \;+\; \Big(\,|1\rangle\langle 1|\,\Big)_s \otimes \mathbb{I}_d,$$

then flip a iff s=0 and d=1 (mixed-control Toffoli: open control on s, closed control on d):



Measuring a and postselecting on outcome 1 realizes the projector

$$P^{(\mathfrak{B}_x)}_{\text{antipara}} = |0\rangle\langle 0|_s \otimes |-\rangle\langle -|_d\,, \qquad \Pr[a{=}1] = \operatorname{Tr}\Big(\big[\,|0\rangle\langle 0|_s \otimes |-\rangle\langle -|_d\,\big]\,\rho\Big).$$

Swapping the target condition to d=0 yields the complementary $P^{(\mathfrak{B}_x)}_{\text{para}}$.

2.2.3 The Global Parasymmetric Projector

Definition 2.23 (Global Parasymmetric Projector)**.** Let $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$ be two Primordial Quantum Singularities, each with modal Hilbert space restricted to the $(0,1)$-sector:

$$\mathcal{H}^{(x)}_{(0,1)},\, \mathcal{H}^{(x')}_{(0,1)} \subset \mathbb{C}^4,$$

and local basis vectors

$$|\mathring{\mathbf{0}}\rangle := |e_1\rangle := \begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad |\mathring{\mathbf{1}}\rangle := |e_2\rangle := \begin{pmatrix}0\\1\\0\\0\end{pmatrix}.$$

The *ontological parasymmetric state* on the bipartite tensor product space is:

$$|\Psi_{\text{para}}\rangle_{xx'} := \frac{1}{\sqrt{2}}\left(|\mathring{\mathbf{0}}\rangle_x \otimes |\mathring{\mathbf{1}}\rangle_{x'} + |\mathring{\mathbf{1}}\rangle_x \otimes |\mathring{\mathbf{0}}\rangle_{x'}\right). \tag{2.22}$$

Conventional Quantum State Realization Under the canonical lexicographic basis of $\mathbb{C}^4 \otimes \mathbb{C}^4 \cong \mathbb{C}^{16}$, where

$$|e_i\rangle \otimes |e_j\rangle \mapsto \mathbf{e}_{4(i-1)+j},$$

the vector $|\Psi_{\text{para}}\rangle_{xx'}$ becomes:

$$|\Psi_{\text{para}}\rangle_{xx'} = \frac{1}{\sqrt{2}}\left(|e_1\rangle_x \otimes |e_2\rangle_{x'} + |e_2\rangle_x \otimes |e_1\rangle_{x'}\right) = \frac{1}{\sqrt{2}}\left(\mathbf{e}_2 + \mathbf{e}_5\right), \tag{2.23}$$

where $\mathbf{e}_k$ denotes the standard basis vector in $\mathbb{C}^{16}$ with a 1 in the k-th position.

Explicitly, this gives:

$$|\Psi_{\text{para}}\rangle_{xx'} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix},$$

with nonzero components in positions 2 and 5 corresponding to the two configurations $(e_1 \otimes e_2)$ and $(e_2 \otimes e_1)$.

Global Parasymmetric Projector The associated rank-1 orthogonal projection operator is:

$$\boxed{P_{\text{para}}^{(xx')} := |\Psi_{\text{para}}\rangle_{xx'}\langle\Psi_{\text{para}}|_{xx'}.} \tag{2.24}$$

Interpretation. This state encodes a non-separable entanglement of Symmetry and Antisymmetry modes across distinct PQS loci x and x', corresponding to a *distributed realization of dialectical synthesis*. The lexicographic tensor ordering ensures a unique representation in conventional quantum mechanics, preserving fidelity between ontological meaning and Hilbert space structure.

Global Parasymmetry: Synthesis as Entanglement The theoretical framework takes a pivotal step by extending the concept of parasymmetry beyond the confines of a single Primordial Quantum Singularity to encompass the relational structure between two distinct singularities, $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$. This extension marks the transition from local to genuinely relational physics within the IQR. The proposed ontological parasymmetric state is defined as:

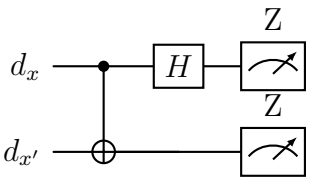
$$|\Psi_{\text{para}}\rangle_{xx'} := \frac{1}{\sqrt{2}} \left(|\mathring{\mathbf{0}}\rangle_x \otimes |\mathring{\mathbf{1}}\rangle_{x'} + |\mathring{\mathbf{1}}\rangle_x \otimes |\mathring{\mathbf{0}}\rangle_{x'} \right)$$

This mathematical form corresponds precisely to one of the four Bell states—the canonical exemplars of maximally entangled two-qubit systems in quantum information theory.

This identification carries profound theoretical implications, revealing the dialectical synthesis between Symmetry and Antisymmetry to be a fundamentally non-local phenomenon, manifesting as a non-separable quantum entanglement distributed across spatially distinct singularities. Under measurement, if the modal state of singularity $\mathfrak{B}_x$ collapses to Symmetry ($|\overset{\circ}{\mathbf{0}}\rangle_x$), then $\mathfrak{B}_{x'}$ necessarily manifests in the Antisymmetry mode ($|\overset{\circ}{\mathbf{1}}\rangle_{x'}$), and conversely. The synthesis therefore exists neither at location x nor at x' individually, but emerges purely through the quantum correlation binding the two singularities.

Within the $\mathbb{C}^{16}$ tensor product space of the combined system, this state admits the explicit representation $\frac{1}{\sqrt{2}}(\mathbf{e}_2 + \mathbf{e}_5)$ under the lexicographic ordering of basis vectors. This mathematical realization confirms that parasymmetric synthesis, when extended to the multi-singularity domain, fundamentally embodies the principle of quantum entanglement—establishing relational coherence as the mechanism through which dialectical synthesis transcends local boundaries to create genuinely non-local quantum structures.

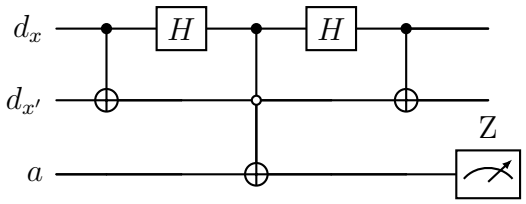
Definition 2.24 (Bell-basis test for $P^{(xx')}_{\text{para}}$ on $\mathcal{H}^{(x)}_{(0,1)} \otimes \mathcal{H}^{(x')}_{(0,1)}$)**.** Let d_x and $d_{x'}$ denote the duality qubits for sites x and x'. A standard Bell-basis demultiplexing followed by Z-readout realizes the rank-1 projector $P^{(xx')}_{\text{para}} = |\Psi_{\text{para}}\rangle\langle\Psi_{\text{para}}|$ via postselection:



Under the inverse Bell map (CNOT then H on d_x), the Bell states are sent to $\{|\Phi^+\rangle, |\Phi^-\rangle, |\Psi^+\rangle, |\Psi^-\rangle\} \mapsto \{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$, so $|\Psi_{\text{para}}\rangle = |\Psi^+\rangle$ produces outcome $(1, 0)$. Thus, for any ρ on $\mathcal{H}^{(x)}_{(0,1)} \otimes \mathcal{H}^{(x')}_{(0,1)}$,

$$\Pr[(d_x, d_{x'}) = (1, 0)] = \mathrm{Tr}\Big(P^{(xx')}_{\text{para}}\,\rho\Big), \quad \rho \xrightarrow{\text{postselect } (1,0)} \frac{P^{(xx')}_{\text{para}}\,\rho\,P^{(xx')}_{\text{para}}}{\mathrm{Tr}(P^{(xx')}_{\text{para}}\rho)}.$$

Definition 2.25 (Coherent flagged realization (Naimark dilation) of $P^{(xx')}_{\text{para}}$)**.** Introduce a flag ancilla a initialized in $|0\rangle_a$. Map to the computational basis, flip a iff the pattern $d_x d_{x'} = 10$ is present, then uncompute:



Here the mixed-control Toffoli uses a *closed* control on d_x (selecting 1) and an *open* control on $d_{x'}$ (selecting 0), so that

$$\Pr[a{=}1] = \mathrm{Tr}\Big(P^{(xx')}_{\text{para}}\,\rho\Big), \qquad \text{and (on } a{=}1\text{) the system is projected by } P^{(xx')}_{\text{para}}.$$

Remark 2.26 (Relation to the lexicographic embedding)**.** With the identification $|\mathring{\mathbf{0}}\rangle \equiv |0\rangle$, $|\mathring{\mathbf{1}}\rangle \equiv |1\rangle$ per site, $|\Psi_{\text{para}}\rangle = \frac{1}{\sqrt{2}}(|01\rangle + |10\rangle)$ and $P^{(xx')}_{\text{para}} = |\Psi^+\rangle\langle\Psi^+|$. Under the full $\mathbb{C}^{16}$ lexicographic ordering of Definition 2.23, these circuits act nontrivially only on the $\mathcal{H}^{(x)}_{(0,1)} \otimes \mathcal{H}^{(x')}_{(0,1)}$ block and as the identity elsewhere.

Remark 2.27 (Nature of the global parasymmetric projector)**.** The operator introduced in Definition 2.23 is *not* a unitary gate but a rank-1 orthogonal *projector/measurement effect* on the duality sector,

$$P^{(xx')}_{\text{para}} \;=\; |\Psi_{\text{para}}\rangle\langle\Psi_{\text{para}}|\,, \qquad |\Psi_{\text{para}}\rangle = \tfrac{1}{\sqrt{2}}\Big(|\mathring{\mathbf{0}}\rangle_x\,|\mathring{\mathbf{1}}\rangle_{x'} + |\mathring{\mathbf{1}}\rangle_x\,|\mathring{\mathbf{0}}\rangle_{x'}\Big)\,,$$

i.e. the Bell state $|\Psi^+\rangle$ on the two $(0,1)$-sector (duality) qubits. Consequently,

$$\Big(P^{(xx')}_{\text{para}}\Big)^\dagger = P^{(xx')}_{\text{para}}, \qquad \Big(P^{(xx')}_{\text{para}}\Big)^2 = P^{(xx')}_{\text{para}},$$

so it is Hermitian, idempotent, positive, and *non-unitary* (a projector rather than a gate) [287]. A convenient Pauli–stabilizer form on the two duality qubits $(d_x, d_{x'})$ is

$$P^{(xx')}_{\text{para}} = \frac{1}{4}\left(\mathbb{I} - Z_{d_x}Z_{d_{x'}}\right)\left(\mathbb{I} + X_{d_x}X_{d_{x'}}\right),$$

i.e. projection onto the simultaneous (-1)-eigenspace of $Z\otimes Z$ and $(+1)$-eigenspace of $X\otimes X$ (the stabilizers of $|\Psi^+\rangle$) [349]. Operationally, $P^{(xx')}_{\text{para}}$ is implemented by a Clifford uncompute to the Bell basis (e.g. CNOT then H on the first duality qubit) followed by computational-basis measurement and *postselection* of the outcome corresponding to $|\Psi^+\rangle$; equivalently, it can be realized via a Naimark dilation with a flagged ancilla and Clifford controls [287, 351].

2.2.4 The Global Anti-Parasymmetric Projector

Definition 2.28. The orthogonal anti-parasymmetric state is defined ontologically as:

$$|\Psi_{\text{antipara}}\rangle_{xx'} := \frac{1}{\sqrt{2}}\left(|\mathring{\mathbf{0}}\rangle_x \otimes |\mathring{\mathbf{1}}\rangle_{x'} - |\mathring{\mathbf{1}}\rangle_x \otimes |\mathring{\mathbf{0}}\rangle_{x'}\right). \tag{2.25}$$

Conventional Quantum State Realization Using the standard embedding:

$$|\mathring{\mathbf{0}}\rangle := |e_1\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad |\mathring{\mathbf{1}}\rangle := |e_2\rangle = \begin{pmatrix}0\\1\\0\\0\end{pmatrix},$$

and under the lexicographic ordering of the basis of $\mathbb{C}^4 \otimes \mathbb{C}^4 \cong \mathbb{C}^{16}$, where:

$$|e_i\rangle \otimes |e_j\rangle \mapsto \mathbf{e}_{4(i-1)+j},$$

we obtain:

$$|\Psi_{\text{antipara}}\rangle_{xx'} = \frac{1}{\sqrt{2}}\left(|e_1\rangle_x \otimes |e_2\rangle_{x'} - |e_2\rangle_x \otimes |e_1\rangle_{x'}\right) = \frac{1}{\sqrt{2}}\left(\mathbf{e}_2 - \mathbf{e}_5\right), \tag{2.26}$$

which expands to:

$$|\Psi_{\text{antipara}}\rangle_{xx'} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ -1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}.$$

Projector The corresponding orthogonal projector is:

$$\boxed{P^{(xx')}_{\text{antipara}} := |\Psi_{\text{antipara}}\rangle_{xx'}\langle\Psi_{\text{antipara}}|_{xx'}.} \tag{2.27}$$

Properties

1. **Orthogonality:**
$$P^{(xx')}_{\text{para}} \cdot P^{(xx')}_{\text{antipara}} = 0.$$
2. **Completeness over the symmetric–antisymmetric subspace:**
$$P^{(xx')}_{\text{para}} + P^{(xx')}_{\text{antipara}} = P^{(xx')}_{\text{exchange}},$$
where $P^{(xx')}_{\text{exchange}}$ projects onto the span:
$$\text{span}\left\{|\mathring{\mathbf{0}}\rangle \otimes |\mathring{\mathbf{1}}\rangle,\ |\mathring{\mathbf{1}}\rangle \otimes |\mathring{\mathbf{0}}\rangle\right\} = \text{span}\left\{\mathbf{e}_2,\ \mathbf{e}_5\right\}.$$

Interpretation. The anti-parasymmetric state $|\Psi_{\text{antipara}}\rangle_{xx'}$ encodes an *entangled modal opposition*—a dialectical structure in which Symmetry and Antisymmetry modes remain in relational conflict across distinct loci. In contrast to the parasymmetric synthesis, this state represents the *logical antithesis* of modal coherence, and its orthogonality ensures a clean partition of the inter-modal entanglement space. The inclusion of both ontological and conventional forms ensures precise mapping between quantum formalism and the duality-structured ontological semantics of Primordial Quantum Singularities.

Global Anti-Parasymmetry: Opposition as Entanglement Following the same theoretical logic, the framework defines the orthogonal anti-parasymmetric state as:

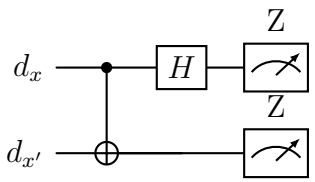
$$|\Psi_{\text{antipara}}\rangle_{xx'} := \frac{1}{\sqrt{2}}\left(|\mathring{\mathbf{0}}\rangle_x \otimes |\mathring{\mathbf{1}}\rangle_{x'} - |\mathring{\mathbf{1}}\rangle_x \otimes |\mathring{\mathbf{0}}\rangle_{x'}\right)$$

This state constitutes another member of the canonical Bell state quartet, distinguished from its parasymmetric counterpart by the crucial minus sign, which introduces a relative phase of π between the two superposed configurations. In quantum mechanics, such phase differences carry genuine physical significance and engender distinct correlational structures. Whereas the parasymmetric state embodies dialectical synthesis, the anti-parasymmetric state represents entangled modal opposition—a configuration of perfect anti-correlation when analyzed in the synthesis/dissonance basis.

Completeness of the Entangled Subspace The corresponding projection operators, $P^{(xx')}_{\text{para}}$ and $P^{(xx')}_{\text{antipara}}$, satisfy the fundamental properties of orthogonality and completeness within the relevant subspace. Their orthogonality ensures mutual exclusivity of the parasymmetric and anti-parasymmetric configurations, while their sum projects onto the entire two-dimensional space spanned by the basis states $\{|\mathring{\mathbf{0}}\rangle_x \otimes |\mathring{\mathbf{1}}\rangle_{x'}, |\mathring{\mathbf{1}}\rangle_x \otimes |\mathring{\mathbf{0}}\rangle_{x'}\}$.

This completeness relation demonstrates that any quantum entanglement between the Symmetry mode of one PQS and the Antisymmetry mode of another admits a unique decomposition into components of pure synthesis ($|\Psi_{\text{para}}\rangle$) and pure opposition ($|\Psi_{\text{antipara}}\rangle$). The mathematical framework thus elevates the abstract principles of dialectical logic from local modal properties to the fundamental architecture of non-local quantum entanglement, establishing a rigorous foundation for the construction of a genuinely relational universe within the IQR.

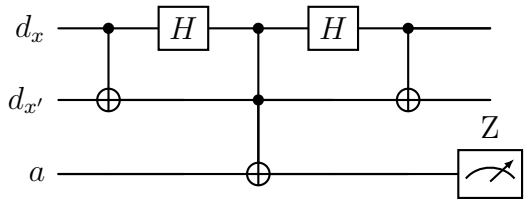
Definition 2.29 (Bell-basis test for $P^{(xx')}_{\text{antipara}}$ on $\mathcal{H}^{(x)}_{(0,1)} \otimes \mathcal{H}^{(x')}_{(0,1)}$)**.** Let d_x and $d_{x'}$ be the duality qubits of sites x, x'. The inverse Bell transform (CNOT then H on d_x) maps $\{|\Phi^+\rangle, |\Phi^-\rangle, |\Psi^+\rangle, |\Psi^-\rangle\} \to \{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$. Thus, postselecting the outcome $(1,1)$ realizes the projector $P^{(xx')}_{\text{antipara}} = |\Psi^-\rangle\langle\Psi^-|$:



For any state ρ on $\mathcal{H}^{(x)}_{(0,1)}\otimes\mathcal{H}^{(x')}_{(0,1)}$,

$$\Pr[(d_x,d_{x'})=(1,1)]=\mathrm{Tr}\Big(P^{(xx')}_{\text{antipara}}\,\rho\Big),\qquad \rho\ \xrightarrow{\text{postselect }(1,1)}\ \frac{P^{(xx')}_{\text{antipara}}\rho\,P^{(xx')}_{\text{antipara}}}{\mathrm{Tr}(P^{(xx')}_{\text{antipara}}\rho)}.$$

Definition 2.30 (Coherent flagged realization (Naimark dilation) of $P^{(xx')}_{\text{antipara}}$)**.** Introduce a flag ancilla a initialized in $|0\rangle_a$. Demultiplex to the computational basis, flip a iff the pattern $d_xd_{x'}=11$ is present, then uncompute:



Then

$$\Pr[a{=}1]=\mathrm{Tr}\Big(P^{(xx')}_{\text{antipara}}\,\rho\Big),\quad \text{and on } a{=}1 \text{ the system is projected by } P^{(xx')}_{\text{antipara}}.$$

Remark 2.31 (Stabilizer form)**.** On the two duality qubits $(d_x,d_{x'})$, the anti-parasymmetric projector admits the Pauli form

$$P^{(xx')}_{\text{antipara}}=\frac{1}{4}\Big(\mathbb{I}-Z_{d_x}Z_{d_{x'}}\Big)\Big(\mathbb{I}-X_{d_x}X_{d_{x'}}\Big),$$

selecting the simultaneous (-1)-eigenspaces of both $Z\otimes Z$ and $X\otimes X$, i.e. the Bell state $|\Psi^-\rangle$.

Remark 2.32 (Nature of the global anti-parasymmetric projector)**.** The operator in eqs. (2.25) and (2.27) is *not* a unitary gate but a rank-1 orthogonal *projector/measurement effect* onto the Bell state

$$P^{(xx')}_{\text{antipara}}\ =\ |\Psi_{\text{antipara}}\rangle\langle\Psi_{\text{antipara}}|\,,\qquad |\Psi_{\text{antipara}}\rangle=\tfrac{1}{\sqrt{2}}\Big(|\mathring{\mathbf{0}}\rangle_x\,|\mathring{\mathbf{1}}\rangle_{x'}-|\mathring{\mathbf{1}}\rangle_x\,|\mathring{\mathbf{0}}\rangle_{x'}\Big)=|\Psi^-\rangle\,.$$

Consequently $P^{(xx')}_{\text{antipara}}$ is Hermitian, idempotent and positive, but non-unitary: $(P^{(xx')}_{\text{antipara}})^\dagger=P^{(xx')}_{\text{antipara}}$, $(P^{(xx')}_{\text{antipara}})^2=P^{(xx')}_{\text{antipara}}$ [287]. On the two duality qubits $(d_x,d_{x'})$ the stabilizer–Pauli form is

$$P^{(xx')}_{\text{antipara}}=\frac{1}{4}\Big(\mathbb{I}-Z_{d_x}Z_{d_{x'}}\Big)\Big(\mathbb{I}-X_{d_x}X_{d_{x'}}\Big),$$

selecting the simultaneous (-1)-eigenspaces of $Z\otimes Z$ and $X\otimes X$, which uniquely characterizes $|\Psi^-\rangle$ within the Bell basis [349]. Operationally, $P^{(xx')}_{\text{antipara}}$ is implemented by Clifford uncompute to the Bell basis (e.g. CNOT followed by H on the first duality qubit), computational-basis measurement, and *postselection* of the $(1,1)$ outcome; equivalently, a Naimark dilation with a flagged ancilla and controlled-Clifford gates realizes the same projector coherently [287, 351].

2.2.5 Multipartite Parasymmetric Entanglement

Definition 2.33 (Multipartite Parasymmetric State)**.** Let $\{\mathfrak{B}_{x_1}, \mathfrak{B}_{x_2}, \ldots, \mathfrak{B}_{x_n}\}$ be a collection of n Primordial Quantum Singularities, each with modal Hilbert space restricted to the $(0,1)$-sector:

$$\mathcal{H}_{(0,1)}^{(x_i)} := \operatorname{span}\left\{ |\overset{\circ}{\mathbf{0}}\rangle_{x_i},\ |\overset{\circ}{\mathbf{1}}\rangle_{x_i} \right\} \cong \mathbb{C}^2.$$

The total multipartite Hilbert space is the ordered tensor product:

$$\mathcal{H}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes n}.$$

The *multipartite parasymmetric state* is defined as the equal-weighted superposition of all configurations in which exactly one site occupies the Antisymmetry mode $|\overset{\circ}{\mathbf{1}}\rangle$ and all others occupy the Symmetry mode $|\overset{\circ}{\mathbf{0}}\rangle$:

$$|\Psi_{\text{para}}^{(n)}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |\overset{\circ}{\mathbf{0}}\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|\overset{\circ}{\mathbf{1}}\rangle_{x_k}} \otimes \cdots \otimes |\overset{\circ}{\mathbf{0}}\rangle_{x_n}. \tag{2.28}$$

In conventional notation (with $|\overset{\circ}{\mathbf{0}}\rangle := |e_1\rangle$, $|\overset{\circ}{\mathbf{1}}\rangle := |e_2\rangle$), this becomes:

$$|\Psi_{\text{para}}^{(n)}\rangle = \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |e_1\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|e_2\rangle_{x_k}} \otimes \cdots \otimes |e_1\rangle_{x_n},$$

with each summand corresponding to one excitation (antisymmetric mode) among n modes.

The associated rank-1 *global parasymmetric projector* is:

$$\boxed{P_{\text{para}}^{(x_1 \ldots x_n)} := |\Psi_{\text{para}}^{(n)}\rangle\langle\Psi_{\text{para}}^{(n)}|.} \tag{2.29}$$

Properties

1. **Permutation Symmetry:** The state $|\Psi_{\text{para}}^{(n)}\rangle$ is invariant under any permutation $\sigma \in S_n$ of the site labels:
$$\hat{\Pi}_\sigma |\Psi_{\text{para}}^{(n)}\rangle = |\Psi_{\text{para}}^{(n)}\rangle,$$
where $\hat{\Pi}_\sigma$ acts by permuting tensor factors.
2. **Genuine Multipartite Entanglement:** For $n \geq 3$, the state cannot be written as a product of states over any bipartition of the tensor product space. The entanglement is irreducibly global.
3. **Mixed Marginals:** The reduced density matrix on any proper subset of the n subsystems is mixed. No proper subset retains pure parasymmetric coherence.

Interpretation. This state embodies a generalized form of *dialectical synthesis* extended across many singularities. At any moment, one site exhibits Antisymmetry while all others manifest Symmetry; yet the global configuration is a coherent superposition of all such arrangements. The result is a nonlocal entanglement structure in which opposites are distributed and bound across space—expressing modal unity through relational variation.

From Bipartite to Multipartite Coherence The theoretical framework proceeds with the natural generalization of dialectical synthesis from bipartite systems to configurations of n singularities, thereby transitioning from simple entanglement to the rich phenomenology of many-body quantum coherence. This extension operates within the total Hilbert space $\mathcal{H}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)}$, constructed as the tensor product of the individual $(0,1)$-subspaces of n Primordial Quantum Singularities.

The State of Distributed Synthesis The ontological principle underlying the multipartite parasymmetric state is elegantly formulated: it represents the equal-weighted superposition of all configurations in which exactly one site occupies the Antisymmetry mode $|\mathring{\mathbf{1}}\rangle$ while all others occupy the Symmetry mode $|\mathring{\mathbf{0}}\rangle$. The translation of this abstract principle into a concrete quantum state yields:

$$|\Psi_{\text{para}}^{(n)}\rangle = \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |e_1\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|e_2\rangle_{x_k}} \otimes \cdots \otimes |e_1\rangle_{x_n},$$

This is in the realized basis vectors $|e_1\rangle$ and $|e_2\rangle$ within each local $\mathbb{C}^2$ subspace, rather than abstract ontological principles. This state corresponds precisely to the W-state of quantum information theory, characterized by the coherent distribution of a single quantum excitation—here manifested as the Antisymmetry mode—across the entire many-body system. The normalization factor $1/\sqrt{n}$ ensures unit probability for the total state.

Properties and Interpretation The multipartite parasymmetric state exhibits several fundamental properties that illuminate its role within the IQR:

1. **Permutation Symmetry:** The state remains invariant under any permutation of the singularity labels, treating every PQS identically. This democratic distribution ensures that synthesis emerges as a collective property rather than being localized to any privileged singularity.

2. **Genuine Multipartite Entanglement:** For systems of three or more singularities, the entanglement structure is irreducibly holistic, resisting decomposition into any collection of bipartite entangled pairs. The quantum coherence manifests only through the indivisible unity of the complete system.

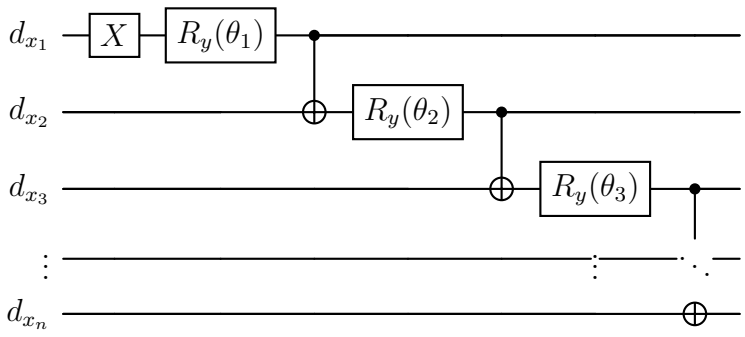
3. **Mixed Marginals:** Tracing out any subset of singularities yields a reduced density matrix corresponding to a mixed state for the remaining subsystem. The quantum purity and coherence are therefore properties exclusive to the complete configuration, vanishing under any partial observation.

These properties establish the multipartite parasymmetric state as the mathematical instantiation of generalized dialectical synthesis extended across multiple singularities. This construction provides the foundational framework for a universe in which relational properties and non-local correlations constitute the primary mechanisms through which structure emerges and complexity unfolds.

Definition 2.34 (Circuit synthesis of $|\Psi^{(n)}_{\text{para}}\rangle$)**.** Let $(d_{x_1}, \dots, d_{x_n})$ be the duality qubits of the n PQSs, with initial register $|\mathring{\mathbf{0}}\rangle^{\otimes n} = |0\rangle^{\otimes n}$. Define angles

$$\theta_k \;:=\; 2\arccos\sqrt{\frac{n-k}{n-k+1}} \qquad (k = 1, \dots, n-1). \tag{2.30}$$

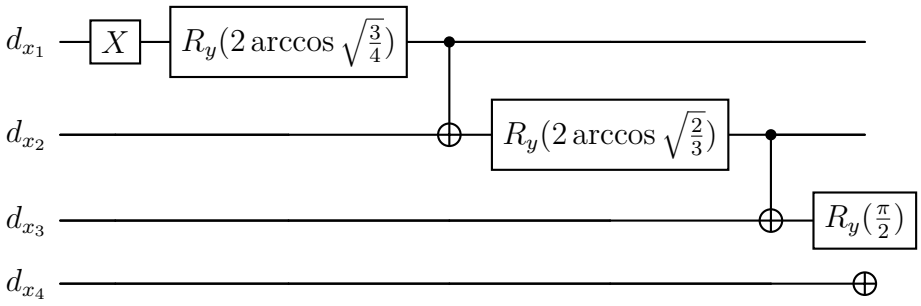
The following ladder of single–qubit R_y rotations and nearest–neighbour CNOTs prepares the multipartite parasymmetric state of eq. (2.28):



Explanation: start from $|10\cdots0\rangle$ by X on d_{x_1}. For each $k = 1, \dots, n-1$, the $R_y(\theta_k)$ adjusts the amplitude so that the *remaining* excitation weight to be distributed over sites $k, \dots, n$ is $\sqrt{\frac{1}{n-k+1}}$, then CNOT $(d_{x_k} \to d_{x_{k+1}})$ coherently "splits" the single excitation to the next site. Induction on k yields the equal-weight single-excitation superposition

$$|\Psi^{(n)}_{\text{para}}\rangle = \frac{1}{\sqrt{n}} \sum_{j=1}^{n} |0\rangle^{\otimes(j-1)} |1\rangle |0\rangle^{\otimes(n-j)} = \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \Big(\bigotimes_{i \neq j} |\mathring{\mathbf{0}}\rangle_{x_i} \Big) \otimes |\mathring{\mathbf{1}}\rangle_{x_j}.$$

Example 2.35 (Explicit n=4 instance)**.** For $n = 4$, the angles are $\theta_1 = 2\arccos\sqrt{\frac{3}{4}}$, $\theta_2 = 2\arccos\sqrt{\frac{2}{3}}$, $\theta_3 = 2\arccos\sqrt{\frac{1}{2}} = \frac{\pi}{2}$, and the circuit is



which prepares $|\Psi^{(4)}_{\text{para}}\rangle = \frac{1}{2}\big(|1000\rangle + |0100\rangle + |0010\rangle + |0001\rangle \big)$ on $(d_{x_1}, d_{x_2}, d_{x_3}, d_{x_4})$.

Remark 2.36 (Gate class and resources)**.** The synthesis uses Clifford+R_y with $n-1$ controlled-NOTs and $n-1$ single-qubit R_y gates, depth $O(n)$ and nearest-neighbour connectivity (as drawn). Any global reordering of sites preserves the target state by the permutation symmetry of Definition 2.33.

2.2.6 Multipartite Anti-Parasymmetric Entanglement

Definition 2.37 (Multipartite Anti-Parasymmetric State)**.** Let $\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ be a collection of n Primordial Quantum Singularities, each with modal Hilbert space restricted to the $(0,1)$-sector:

$$\mathcal{H}_{(0,1)}^{(x_i)} := \operatorname{span}\left\{ |\mathring{\mathbf{0}}\rangle_{x_i},\ |\mathring{\mathbf{1}}\rangle_{x_i} \right\} \cong \mathbb{C}^2,$$

and total Hilbert space:

$$\mathcal{H}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Let the *parasymmetric state* be defined as:

$$|\Psi_{\text{para}}^{(n)}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |\phi_k\rangle, \quad \text{where } |\phi_k\rangle := \bigotimes_{i=1}^{n} \chi_i^{(k)}, \quad \chi_i^{(k)} := \begin{cases} |\mathring{\mathbf{1}}\rangle_{x_i} & \text{if } i = k, \\ |\mathring{\mathbf{0}}\rangle_{x_i} & \text{if } i \neq k. \end{cases}$$

We now define the *orthonormalized anti-parasymmetric state*, valid for all n, as:

$$|\widetilde{\Psi}_{\text{antipara}}^{(n)}\rangle := \frac{|\Psi_{\text{antipara}}^{(n)}\rangle - \gamma_n |\Psi_{\text{para}}^{(n)}\rangle}{\sqrt{1-\gamma_n^2}}, \quad \text{where } \gamma_n := \frac{1}{n} \sum_{k=1}^{n} (-1)^{k-1}. \tag{2.31}$$

Here,

$$|\Psi_{\text{antipara}}^{(n)}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} (-1)^{k-1} |\phi_k\rangle$$

is the (generally non-orthogonal) alternating single-excitation superposition.

Conventional Quantum Form Using the identifications $|\mathring{\mathbf{0}}\rangle := |e_1\rangle$, $|\mathring{\mathbf{1}}\rangle := |e_2\rangle$, the basis state $|\phi_k\rangle$ becomes:

$$|\phi_k\rangle = |e_1\rangle_{x_1} \otimes \cdots \otimes |e_2\rangle_{x_k} \otimes \cdots \otimes |e_1\rangle_{x_n},$$

so the normalized orthogonal anti-parasymmetric state is:

$$|\widetilde{\Psi}_{\text{antipara}}^{(n)}\rangle = \sum_{k=1}^{n} \left[\frac{(-1)^{k-1} - \gamma_n}{\sqrt{n(1-\gamma_n^2)}} \right] |\phi_k\rangle.$$

Projector The corresponding rank-1 projector is:

$$\boxed{P_{\widetilde{\text{antipara}}}^{(x_1 \ldots x_n)} := |\widetilde{\Psi}_{\text{antipara}}^{(n)}\rangle\langle\widetilde{\Psi}_{\text{antipara}}^{(n)}|.} \tag{2.32}$$

Properties

1. **Universal Orthogonality:**

$$\langle\widetilde{\Psi}_{\text{antipara}}^{(n)}|\Psi_{\text{para}}^{(n)}\rangle = 0 \quad \text{for all } n \in \mathbb{N}.$$

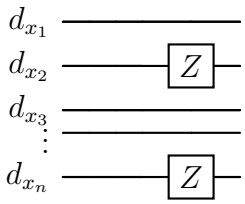
2. **Normalization:**
$$\|\widetilde{\Psi}^{(n)}_{\text{antipara}}\| = 1.$$

3. **Span Complementarity:** The states $|\Psi^{(n)}_{\text{para}}\rangle$ and $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ form an orthonormal basis of the excitation sector:
$$\mathcal{H}_{\text{exc}} := \text{span}\,\{|\phi_k\rangle \mid 1 \le k \le n\} \subset \mathcal{H}^{(n)}.$$

Interpretation. The state $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ realizes the true logical complement to multipartite parasymmetry. It represents a *canonically orthogonal* configuration of distributed modal dissonance—an antithesis to global synthesis—valid across all cardinalities of Primordial Quantum Singularities. This corrected state ensures structural consistency within the Fourfold Dialectic Algebra of Symmetry without parity restrictions.

Definition 2.38 (Circuit synthesis of $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$)**.** Let $(d_{x_1}, \ldots, d_{x_n})$ be the duality qubits initialized in $|\mathring{\mathbf{0}}\rangle^{\otimes n} = |0\rangle^{\otimes n}$. Define target coefficients
$$\tilde{c}_k := \frac{(-1)^{k-1} - \gamma_n}{\sqrt{n(1-\gamma_n^2)}}, \qquad \gamma_n = \frac{1}{n}\sum_{j=1}^{n}(-1)^{j-1} = \begin{cases} 0, & n \text{ even}, \\ \frac{1}{n}, & n \text{ odd}, \end{cases}$$
so that $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle = \sum_{k=1}^{n} \tilde{c}_k\, |\phi_k\rangle$ with $|\phi_k\rangle = |0\rangle^{\otimes(k-1)}\,|1\rangle\,|0\rangle^{\otimes(n-k)}$.

Definition 2.39 (Even-n (simplified): W state + alternating Z phases)**.** For n even, $\gamma_n = 0$ and $\tilde{c}_k = \frac{1}{\sqrt{n}}(-1)^{k-1}$. Prepare $|\Psi^{(n)}_{\text{para}}\rangle$ as in Definition 2.34, then apply Z to every even-indexed duality qubit to imprint the alternating sign:

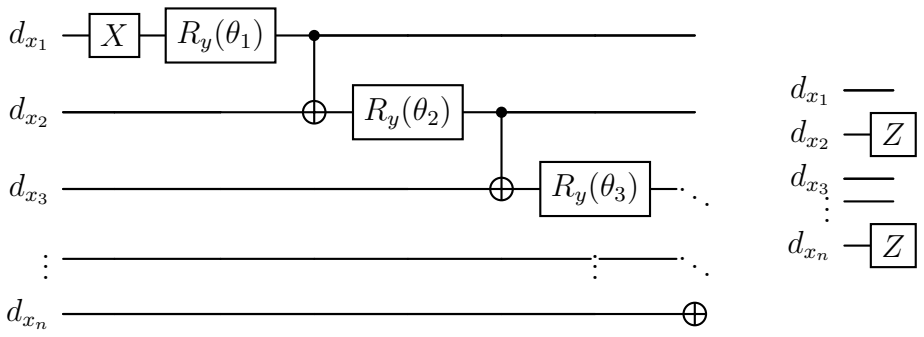


This yields $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle = \frac{1}{\sqrt{n}}\sum_k (-1)^{k-1}\,|\phi_k\rangle$, already orthogonal to $|\Psi^{(n)}_{\text{para}}\rangle$.

Definition 2.40 (Odd-n (general amplitudes): ladder with tail-norm angles + parity phases)**.** For n odd, let $m_k := |\tilde{c}_k|$ and define tail sums $S_k := \sum_{j=k}^{n} m_j^2$ with $S_{n+1} := 0$. Set
$$\theta_k := 2\arccos\sqrt{\frac{S_{k+1}}{S_k}} \qquad (k = 1, \ldots, n-1).$$

The following ladder prepares the magnitudes m_k (starting from $|10\cdots0\rangle$) and then applies

parity phases to set the signs $\mathrm{sgn}(\tilde{c}_k) = (-1)^{k-1}$:



The first ladder ensures amplitudes $\{m_k\}$ via the tail-norm choice of $\{\theta_k\}$; the trailing Z gates on even indices impose the alternating signs, producing $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle = \sum_k \tilde{c}_k \, |\phi_k\rangle$ exactly.

Remark 2.41 (Resources and correctness)**.** Even-n: uses the parasymmetric preparation of Definition 2.34 plus $n/2$ single-qubit Z gates. Odd-n: uses $n-1$ CNOTs, $n-1$ R_y rotations with angles from $\{S_k\}$, and $\lfloor n/2 \rfloor$ single-qubit Z gates. By construction, the state equals the orthonormalized anti-parasymmetric vector of eq. (2.31), i.e., $\langle \widetilde{\Psi}^{(n)}_{\text{antipara}} | \Psi^{(n)}_{\text{para}} \rangle = 0$ and $\| \, |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle \| = 1$.

The Gram-Schmidt Orthogonalization The mathematical resolution employs the Gram-Schmidt orthogonalization process—the standard procedure for constructing an orthonormal basis from linearly independent vectors. This approach ensures mathematical rigor while preserving the dialectical structure of the framework.

The construction begins with two fundamental states:

- The parasymmetric (W-state): $|\Psi^{(n)}_{\text{para}}\rangle = \frac{1}{\sqrt{n}} \sum_k |\phi_k\rangle$
- The original anti-parasymmetric state: $|\Psi^{(n)}_{\text{antipara}}\rangle = \frac{1}{\sqrt{n}} \sum_k (-1)^{k-1} |\phi_k\rangle$

The inner product between these states yields the projection coefficient $\gamma_n := \langle \Psi^{(n)}_{\text{para}} | \Psi^{(n)}_{\text{antipara}} \rangle = \frac{1}{n} \sum_k (-1)^{k-1}$, which evaluates to non-zero values for odd n, identifying the source of non-orthogonality in the construction.

The orthogonalization procedure constructs a modified anti-parasymmetric state by removing the component parallel to the parasymmetric state:

$$|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle \propto |\Psi^{(n)}_{\text{antipara}}\rangle - \gamma_n |\Psi^{(n)}_{\text{para}}\rangle$$

This construction guarantees orthogonality to $|\Psi^{(n)}_{\text{para}}\rangle$ by design, with the normalization factor $1/\sqrt{1-\gamma_n^2}$ ensuring unit norm for the resulting state.

The Final Form and Properties The complete algebraic expression for the orthogonalized state takes the form:

$$|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle = \sum_{k=1}^{n} \left[\frac{(-1)^{k-1} - \gamma_n}{\sqrt{n(1-\gamma_n^2)}} \right] |\phi_k\rangle$$

This construction exhibits the following essential properties:

1. **Universal Orthogonality:** The modified state maintains orthogonality to the parasymmetric state for all values of n, removing the parity-dependent restriction.

2. **Proper Normalization:** The state vector possesses unit norm, satisfying the fundamental requirement of quantum mechanical state vectors.

3. **Span Complementarity:** The parasymmetric state $|\Psi^{(n)}_{\text{para}}\rangle$ and the orthogonalized anti-parasymmetric state $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ constitute a complete orthonormal basis for the two-dimensional coherence plane within the single-excitation sector.

The formulation reveals a deeper physical significance: the genuine state of modal dissonance transcends a simple alternating sum, emerging instead as a complex superposition defined relationally with respect to its dialectical opposite. This state represents precisely that configuration which remains after all parasymmetric coherence has been projected away—a mathematical embodiment of pure antithesis.

The orthogonalized state $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ thus constitutes the canonically orthogonal configuration of distributed modal dissonance, serving as the true dialectical antithesis to global synthesis. This construction ensures the structural integrity of the Fourfold Dialectic Algebra across all multipartite configurations, eliminating artificial restrictions on system size while preserving the fundamental oppositional structure central to the IQR.

2.2.7 Local and Pairwise Coherence Parasymmetric Generator

Definition 2.42 (Local and Pairwise Coherence Parasymmetric Generator $\hat{F}^{(2)}_{\text{para}}$)**.** Let $\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ be a configuration of n Primordial Quantum Singularities, each with modal subspace

$$\mathcal{H}^{(x_i)}_{(0,1)} := \text{span}\left\{ |\mathring{\mathbf{0}}\rangle_{x_i},\ |\mathring{\mathbf{1}}\rangle_{x_i} \right\} \subset \mathbb{C}^4,$$

and let the global parasymmetric modal Hilbert space be defined as

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Let $P^{(x_i x_j)}_{\text{para}}$ and $P^{(x_i x_j)}_{\text{antipara}}$ denote the orthogonal rank-1 projectors onto the parasymmetric and anti-parasymmetric two-site entangled states:

$$|\Psi^{(ij)}_{\text{para}}\rangle := \frac{1}{\sqrt{2}} \left(|\mathring{\mathbf{0}}\rangle_{x_i} \otimes |\mathring{\mathbf{1}}\rangle_{x_j} + |\mathring{\mathbf{1}}\rangle_{x_i} \otimes |\mathring{\mathbf{0}}\rangle_{x_j} \right), \tag{2.33}$$

$$|\Psi^{(ij)}_{\text{antipara}}\rangle := \frac{1}{\sqrt{2}} \left(|\mathring{\mathbf{0}}\rangle_{x_i} \otimes |\mathring{\mathbf{1}}\rangle_{x_j} - |\mathring{\mathbf{1}}\rangle_{x_i} \otimes |\mathring{\mathbf{0}}\rangle_{x_j} \right), \tag{2.34}$$

with corresponding projectors:

$$P_{\text{para}}^{(x_i x_j)} := |\Psi_{\text{para}}^{(ij)}\rangle\langle\Psi_{\text{para}}^{(ij)}|, \tag{2.35}$$

$$P_{\text{antipara}}^{(x_i x_j)} := |\Psi_{\text{antipara}}^{(ij)}\rangle\langle\Psi_{\text{antipara}}^{(ij)}|. \tag{2.36}$$

Conventional Quantum State Realization We adopt the identification:

$$|\mathring{\mathbf{0}}\rangle := |e_1\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad |\mathring{\mathbf{1}}\rangle := |e_2\rangle = \begin{pmatrix}0\\1\\0\\0\end{pmatrix},$$

which allows us to express the entangled states explicitly in tensor product form.

The *parasymmetric state* becomes:

$$\begin{aligned}|\Psi_{\text{para}}^{(ij)}\rangle &= \frac{1}{\sqrt{2}}\left(\begin{pmatrix}1\\0\\0\\0\end{pmatrix}_{x_i} \otimes \begin{pmatrix}0\\1\\0\\0\end{pmatrix}_{x_j} + \begin{pmatrix}0\\1\\0\\0\end{pmatrix}_{x_i} \otimes \begin{pmatrix}1\\0\\0\\0\end{pmatrix}_{x_j}\right)\\ &= \frac{1}{\sqrt{2}}\left(|e_1\rangle_{x_i} \otimes |e_2\rangle_{x_j} + |e_2\rangle_{x_i} \otimes |e_1\rangle_{x_j}\right),\end{aligned}$$

and the *anti-parasymmetric state* becomes:

$$\begin{aligned}|\Psi_{\text{antipara}}^{(ij)}\rangle &= \frac{1}{\sqrt{2}}\left(\begin{pmatrix}1\\0\\0\\0\end{pmatrix}_{x_i} \otimes \begin{pmatrix}0\\1\\0\\0\end{pmatrix}_{x_j} - \begin{pmatrix}0\\1\\0\\0\end{pmatrix}_{x_i} \otimes \begin{pmatrix}1\\0\\0\\0\end{pmatrix}_{x_j}\right)\\ &= \frac{1}{\sqrt{2}}\left(|e_1\rangle_{x_i} \otimes |e_2\rangle_{x_j} - |e_2\rangle_{x_i} \otimes |e_1\rangle_{x_j}\right).\end{aligned}$$

Definition of the Generator Define the *Local and Pairwise Hermitian Parasymmetric Generator* as:

$$\boxed{\hat{F}_{\text{para}}^{(pair)} := \sum_{i<j} J_{ij}\left(P_{\text{para}}^{(x_i x_j)} - P_{\text{antipara}}^{(x_i x_j)}\right),} \tag{2.37}$$

where $J_{ij} \in \mathbb{R}$ is a symmetric real-valued coupling matrix, satisfying $J_{ij} = J_{ji}$.

Properties

1. **Hermiticity:** Each projector is Hermitian, hence $\hat{F}_{\text{para}}^{(2)}$ is Hermitian.
2. **Projector Orthogonality:**
$$P_{\text{para}}^{(x_i x_j)} \cdot P_{\text{antipara}}^{(x_i x_j)} = 0.$$

3. **Eigenstructure:**

   - Acts nontrivially only on the symmetric–antisymmetric subspace:

$$\mathcal{H}^{(ij)}_{\text{sym/antisym}} := \text{span}\left\{|\Psi^{(ij)}_{\text{para}}\rangle,\ |\Psi^{(ij)}_{\text{antipara}}\rangle\right\} \subset \mathcal{H}^{(x_i)}_{(0,1)} \otimes \mathcal{H}^{(x_j)}_{(0,1)}.$$

   - On this subspace, the operator has eigenvalues $\pm J_{ij}$.

4. **Limitation:** $\hat{F}^{(2)}_{\text{para}}$ does not in general diagonalize the full multipartite parasymmetric states such as:

$$|\Psi^{(n)}_{\text{para}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |\mathring{\mathbf{0}}\rangle_{x_1} \otimes \cdots \otimes |\mathring{\mathbf{1}}\rangle_{x_k} \otimes \cdots \otimes |\mathring{\mathbf{0}}\rangle_{x_n},$$

   unless $n = 2$.

Interpretation. The generator $\hat{F}^{(pair)}_{\text{para}}$ measures the extent to which each PQS pair (x_i, x_j) is in a state of *modal synthesis* (parasymmetry) or *modal dissonance* (anti-parasymmetry), and enables *coherent transitions* in those modes. It defines a pairwise-interaction-based dynamic on the parasymmetric subspace $\mathcal{H}^{(n)}_{\text{para}}$, without resolving higher-order multipartite structure.

2.2.8 Multipartite Modal-Class Parasymmetric Generator

Definition 2.43 (Global Modal-Class Parasymmetric Generator $\hat{F}^{(n)}_{\text{para}}$)**.** Let $\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ be a configuration of n Primordial Quantum Singularities, each with parasymmetric modal subspace

$$\mathcal{H}^{(x_i)}_{(0,1)} := \text{span}\left\{|\mathring{\mathbf{0}}\rangle_{x_i},\ |\mathring{\mathbf{1}}\rangle_{x_i}\right\} \subset \mathbb{C}^4,$$

and total parasymmetric Hilbert space

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Ontological Modal-Class States Define the *multipartite parasymmetric state*:

$$|\Psi^{(n)}_{\text{para}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |\mathring{\mathbf{0}}\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|\mathring{\mathbf{1}}\rangle_{x_k}} \otimes \cdots \otimes |\mathring{\mathbf{0}}\rangle_{x_n}, \tag{2.38}$$

and the anti-parasymmetric complement:

$$|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle := \text{normalized projection of } |\Psi^{(n)}_{\text{antipara}}\rangle \text{ orthogonal to } |\Psi^{(n)}_{\text{para}}\rangle. \tag{2.39}$$

Conventional Quantum State Realization Using the identifications:

$$|\overset{\circ}{\mathbf{0}}\rangle := |e_1\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad |\overset{\circ}{\mathbf{1}}\rangle := |e_2\rangle = \begin{pmatrix}0\\1\\0\\0\end{pmatrix},$$

we rewrite the multipartite parasymmetric state as:

$$|\Psi^{(n)}_{\text{para}}\rangle = \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |e_1\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|e_2\rangle_{x_k}} \otimes \cdots \otimes |e_1\rangle_{x_n},$$

which lies entirely in the *single-excitation sector* of $(\mathbb{C}^2)^{\otimes n} \subset (\mathbb{C}^4)^{\otimes n}$.

Projectors Define the orthogonal projectors:

$$P^{(x_1 \ldots x_n)}_{\text{para}} := |\Psi^{(n)}_{\text{para}}\rangle\langle\Psi^{(n)}_{\text{para}}|, \tag{2.40}$$

$$P^{\widetilde{(x_1 \ldots x_n)}}_{\text{antipara}} := |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle\langle\widetilde{\Psi}^{(n)}_{\text{antipara}}|. \tag{2.41}$$

Generator Definition The global modal-class parasymmetric generator is defined via spectral decomposition:

$$\boxed{\hat{F}^{(n)}_{\text{para}} := E_+ \cdot P^{(x_1 \ldots x_n)}_{\text{para}} + E_- \cdot P^{\widetilde{(x_1 \ldots x_n)}}_{\text{antipara}} + \sum_{\gamma} E_\gamma \cdot P_\gamma,} \tag{2.42}$$

where:

- $E_+, E_- \in \mathbb{R}$ are the eigenvalues of the parasymmetric and anti-parasymmetric multipartite states;
- P_γ are orthogonal projectors completing the spectral decomposition of $\hat{F}^{(n)}_{\text{para}}$;
- $\sum_\gamma P_\gamma = \mathbb{I}_{\text{para}} - P^{(x_1 \ldots x_n)}_{\text{para}} - P^{\widetilde{(x_1 \ldots x_n)}}_{\text{antipara}}$.

Properties

1. **Hermiticity:** All projectors are orthogonal and Hermitian.
2. **Spectral Resolution:**

$$\hat{F}^{(n)}_{\text{para}} = \sum_{\alpha} E_\alpha P_\alpha, \quad P^\dagger_\alpha = P_\alpha, \quad P_\alpha P_\beta = \delta_{\alpha\beta} P_\alpha.$$

3. **Eigenstructure:**

$$\hat{F}^{(n)}_{\text{para}} |\Psi^{(n)}_{\text{para}}\rangle = E_+ |\Psi^{(n)}_{\text{para}}\rangle, \quad \hat{F}^{(n)}_{\text{para}} |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle = E_- |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle.$$

4. **Modal Sector Invariance:**

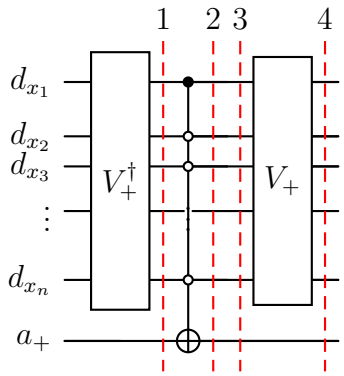
$$\hat{F}^{(n)}_{\text{para}} : \mathcal{H}^{(n)}_{\text{para}} \to \mathcal{H}^{(n)}_{\text{para}}.$$

Interpretation. The operator $\hat{F}^{(n)}_{\text{para}}$ defines a global observable that distinguishes between coherent synthesis and structured dissonance across all n singularities. Unlike pairwise interaction terms, this generator respects the total *modal-class entanglement structure* of the system, enabling dynamics governed by the full dialectical configuration of Primordial Quantum Singularities.

Definition 2.44 (Eigenstate "flag" isometries for $P^{(x_1\ldots x_n)}_{\text{para}}$ and $P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}}$)**.** Let $(d_{x_1},\ldots,d_{x_n})$ denote the duality qubits. Let V_+ be the state-preparation unitary of Definition 2.34 such that $V_+\,|10\cdots0\rangle = |\Psi^{(n)}_{\text{para}}\rangle$, and let V_- be the unitary of Definition 2.38 such that $V_-\,|10\cdots0\rangle = |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$. Introduce single-qubit ancillae a_+, a_- initialized in $|0\rangle$ and define the flagged projectors

$$\text{Flag}_+ := V_+\left(\prod_{j=2}^{n}\text{CTRL}_{d_{x_j}=0}\right)\text{CTRL}_{d_{x_1}=1}\,\text{X}_{a_+}\,V_+^\dagger,$$
$$\text{Flag}_- := V_-\left(\prod_{j=2}^{n}\text{CTRL}_{d_{x_j}=0}\right)\text{CTRL}_{d_{x_1}=1}\,\text{X}_{a_-}\,V_-^\dagger.$$

i.e. multi-controlled flips of $a_\pm$ conditioned on the pattern $d_{x_1}=1$, $d_{x_2}=\cdots=d_{x_n}=0$ *after* uncomputing to the preparation seeds via $V_\pm^\dagger$. These realize coherent membership tests for the rank-1 projectors $P^{(x_1\ldots x_n)}_{\text{para}}$ and $P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}}$.



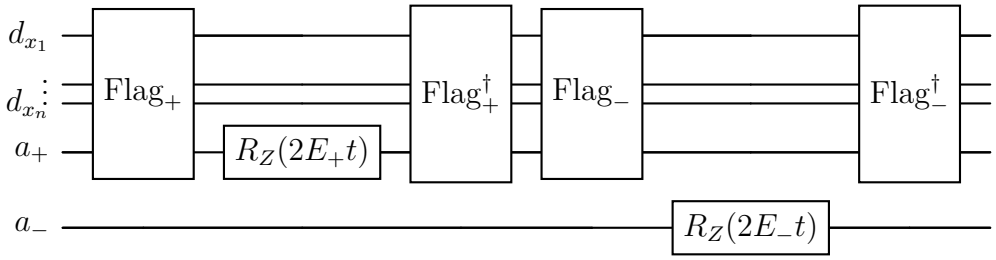
(Replace V_+ by V_- and a_+ by a_- for Flag_-.)

Definition 2.45 (Time evolution $U_{\text{para}}(t) = e^{-it\,\hat{F}^{(n)}_{\text{para}}}$ via phase kickback)**.** Given the spectral form in eq. (2.42),

$$\hat{F}^{(n)}_{\text{para}} = E_+\,P^{(x_1\ldots x_n)}_{\text{para}} + E_-\,P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}} + \sum_{\gamma} E_\gamma P_\gamma,$$

the unitary $U_{\text{para}}(t) = e^{-it\hat{F}^{(n)}_{\text{para}}}$ is implemented on the encoded subspace by sequential

conditional phases using the flags from Definition 2.44:



Here each $R_Z(2E_\pm t)$ applies a phase only when the corresponding ancilla is in $|1\rangle$, yielding a conditional phase $e^{-itE_\pm}$ on the targeted eigenspace. The P_γ sector can be assigned a uniform offset $E_\perp$ (global phase) or further resolved by additional flagged projectors if available.

Remark 2.46 (Measurement of $\hat{F}^{(n)}_{\text{para}}$)**.** Expectation values $\langle \hat{F}^{(n)}_{\text{para}} \rangle_\rho$ can be obtained by a Hadamard test with a single control ancilla c and the controlled version of $U_{\text{para}}(t)$ from Definition 2.45; sweeping t enables phase estimation on the two-dimensional eigen-subspace $\text{span}\{|\Psi^{(n)}_{\text{para}}\rangle, |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle\}$, while leaving the orthogonal complement invariant up to a known phase.

Remark 2.47 (Gate class and resources)**.** The construction uses Clifford unitaries ($V_\pm$ built from CNOTs and R_y rotations) plus multi-controlled X/Z and single-qubit R_Z phases. Depth is $O(n)$ for the $V_\pm$ ladders (nearest-neighbour layout), plus the cost of an n-controlled Toffoli for flagging (log-depth with ancillae using standard decomposition). Since the projector flags commute, the two phase-kickback segments can be applied in any order.

2.2.9 Multipartite Modal-Class Anti-Parasymmetric Generator

Definition 2.48 (Orthogonalized Anti-Parasymmetric Modal-Class State)**.** Let

$$\{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$$

be a configuration of n Primordial Quantum Singularities, each with modal subspace

$$\mathcal{H}^{(x_i)}_{(0,1)} := \text{span}\left\{ |\mathring{\mathbf{0}}\rangle_{x_i},\ |\mathring{\mathbf{1}}\rangle_{x_i} \right\} \subset \mathbb{C}^4,$$

and global parasymmetric modal Hilbert space

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Conventional Quantum State Realization Recall the identifications:

$$|\mathring{\mathbf{0}}\rangle := |e_1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad |\mathring{\mathbf{1}}\rangle := |e_2\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}.$$

The *parasymmetric W-state* is given by:

$$|\Psi^{(n)}_{\text{para}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |\mathring{\mathbf{0}}\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|\mathring{\mathbf{1}}\rangle_{x_k}} \otimes \cdots \otimes |\mathring{\mathbf{0}}\rangle_{x_n}. \tag{2.43}$$

Then the *parasymmetric W-state* becomes:

$$|\Psi^{(n)}_{\text{para}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} |e_1\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|e_2\rangle_{x_k}} \otimes \cdots \otimes |e_1\rangle_{x_n}, \tag{2.44}$$

i.e., it is the uniform superposition over all configurations in which exactly one site occupies $|e_2\rangle$ (the antisymmetric mode) and all others occupy $|e_1\rangle$ (the symmetric mode).

The *unadjusted anti-parasymmetric configuration* is:

$$|\Psi^{(n)}_{\text{antipara}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} (-1)^{k-1} |\mathring{\mathbf{0}}\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|\mathring{\mathbf{1}}\rangle_{x_k}} \otimes \cdots \otimes |\mathring{\mathbf{0}}\rangle_{x_n}. \tag{2.45}$$

Likewise, the *unadjusted anti-parasymmetric configuration* becomes:

$$|\Psi^{(n)}_{\text{antipara}}\rangle := \frac{1}{\sqrt{n}} \sum_{k=1}^{n} (-1)^{k-1} |e_1\rangle_{x_1} \otimes \cdots \otimes \underset{k\text{-th}}{|e_2\rangle_{x_k}} \otimes \cdots \otimes |e_1\rangle_{x_n}, \tag{2.46}$$

in which each term in the superposition acquires an alternating sign $(-1)^{k-1}$, encoding structured modal dissonance across the configuration.

These are both elements of the single-excitation subspace:

$$\mathcal{H}^{(n)}_{\text{exc}} := \text{span} \left\{ |e_2\rangle_{x_k} \otimes \bigotimes_{i \neq k} |e_1\rangle_{x_i} \;\middle|\; k = 1, \ldots, n \right\} \subset (\mathbb{C}^2)^{\otimes n}.$$

Then the *orthogonalized anti-parasymmetric modal-class state* is defined as the normalized component of $|\Psi^{(n)}_{\text{antipara}}\rangle$ orthogonal to $|\Psi^{(n)}_{\text{para}}\rangle$:

$$|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle := \frac{1}{\sqrt{1 - |\langle \Psi^{(n)}_{\text{para}} | \Psi^{(n)}_{\text{antipara}} \rangle|^2}} \left(|\Psi^{(n)}_{\text{antipara}}\rangle - \langle \Psi^{(n)}_{\text{para}} | \Psi^{(n)}_{\text{antipara}} \rangle \cdot |\Psi^{(n)}_{\text{para}}\rangle \right). \tag{2.47}$$

This state satisfies:

$$\langle \Psi^{(n)}_{\text{para}} | \widetilde{\Psi}^{(n)}_{\text{antipara}} \rangle = 0, \tag{2.48}$$

$$\| \widetilde{\Psi}^{(n)}_{\text{antipara}} \| = 1. \tag{2.49}$$

Interpretation. This orthogonalized state represents a genuine modal-class dissonance: a configuration of global anti-synthesis that is orthogonal to the W-state's global synthesis. It resolves the ambiguity in the case of odd n, where the original $|\Psi^{(n)}_{\text{antipara}}\rangle$ is not orthogonal to the parasymmetric mode.

Definition 2.49 (Global modal-class anti-parasymmetric generator)**.** Let $P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}} := |\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle\langle\widetilde{\Psi}^{(n)}_{\text{antipara}}|$, where $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ is the orthogonalized anti-parasymmetric state from Definition 2.48, and let $\mathbb{I}_{\text{exc}} := \sum_{k=1}^{n} |\phi_k\rangle\langle\phi_k|$ project onto the single-excitation sector. Define the generator (up to a global phase) by the spectral form

$$\hat{F}^{(n)}_{\widetilde{\text{antipara}}} := E_- \, P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}} + E_\perp \, (\mathbb{I}_{\text{exc}} - P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}}), \tag{2.50}$$

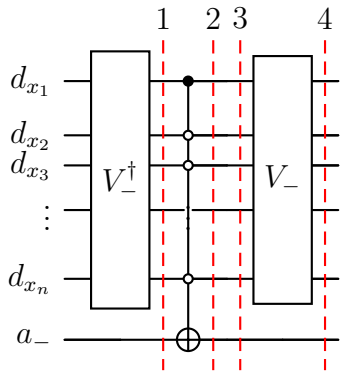
so that $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ is an eigenstate with eigenvalue E_- and any orthogonal single-excitation vector has eigenvalue $E_\perp$. The corresponding evolution is

$$U_-(t) := e^{-it\hat{F}^{(n)}_{\widetilde{\text{antipara}}}} = e^{-itE_\perp}\Big[\, \mathbb{I}_{\text{exc}} + \big(e^{-it(E_- - E_\perp)} - 1\big) P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}} \,\Big].$$

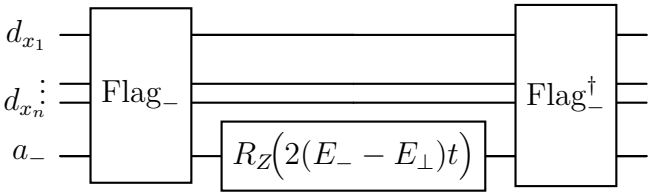
Definition 2.50 (Flag isometry for $P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}}$)**.** Let V_- be the state-preparation unitary that maps the seed $|10\cdots0\rangle$ to $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ (see the synthesis circuit in Definition 2.38). With an ancilla a_- initialized in $|0\rangle$, define the coherent flag

$$\text{Flag}_- \;:=\; V_- \Big(\text{CTRL}_{d_{x_1}=1} \prod_{j=2}^{n} \text{CTRL}_{d_{x_j}=0} \Big) \, X_{a_-} \, V_-^\dagger,$$

i.e. uncompute to the seed, flip a_- iff the pattern $d_{x_1}{=}1$ and $d_{x_2}{=}\cdots{=}d_{x_n}{=}0$ holds, then re-compute. This realizes a coherent membership test for $P^{(x_1\ldots x_n)}_{\widetilde{\text{antipara}}}$.



Definition 2.51 (Phase-kickback implementation of $U_-(t)$)**.** Using Definition 2.50, implement $U_-(t)$ (up to the global phase $e^{-itE_\perp}$) by:



The R_Z on a_- imparts phase $e^{-it(E_- - E_\perp)}$ only when the system is in the flagged subspace $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$, producing the desired evolution in eq. (2.50).

Remark 2.52 (Two-eigenspace resolution (optional))**.** If a distinct phase is also required on the parasymmetric eigenstate, add a second flag Flag_+ (cf. Definition 2.34) and apply an $R_Z(2(E_+ - E_\perp)t)$ on a second ancilla a_+ between Flag_+ and $\mathrm{Flag}_+^\dagger$. Since the flags commute (orthogonal projectors), the two segments may be executed in any order.

Remark 2.53 (Resources)**.** The construction uses the state-preparation unitary V_- (depth $O(n)$ with $n-1$ CNOTs and $n-1$ rotations), one n-controlled Toffoli (log-depth with ancillae via standard decompositions), and a single-qubit R_Z rotation for the phase.

2.2.10 The β Generalized Decoupled Unitary Evolution

Definition 2.54 (β Generalized Decoupled Unitary Parasymmetric Operator)**.** Let $\mathcal{X}_q^{(n)} = \{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ be a configuration of n Primordial Quantum Singularities (PQSs), with parasymmetric modal subspace:

$$\mathcal{H}_{\text{para}}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Let $\mathcal{P} = \{X_1, X_2, \ldots, X_k\}$ be a partition of the PQS configuration into disjoint blocks:

$$X_\beta \subseteq \mathcal{X}_q^{(n)}, \quad X_\beta \cap X_{\beta'} = \emptyset \text{ for } \beta \neq \beta', \quad \bigcup_\beta X_\beta = \mathcal{X}_q^{(n)}.$$

To each block X_β, assign a Hermitian generator $\hat{F}_{\text{para}}^{(\beta)}$ acting on the parasymmetric modal space:

$$\hat{F}_{\text{para}}^{(\beta)} : \mathcal{H}_{\text{para}}^{(X_\beta)} \to \mathcal{H}_{\text{para}}^{(X_\beta)},$$

where $\mathcal{H}_{\text{para}}^{(X_\beta)} := \bigotimes_{x_i \in X_\beta} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes |X_\beta|}$.

Each block evolves unitarily via:

$$U_\beta := e^{i\hat{F}_{\text{para}}^{(\beta)}}.$$

Then the *Generalized Decoupled Unitary Parasymmetric Operator* is defined as the tensor product:

$$\boxed{U_N^{(\beta)} := \bigotimes_{\beta \in \mathcal{P}} U_\beta = \bigotimes_{\beta \in \mathcal{P}} e^{i\hat{F}_{\text{para}}^{(\beta)}}.} \tag{2.51}$$

Interpretation. This operator describes a general class of *factorized evolutions*, in which each block X_β undergoes autonomous parasymmetric evolution under an internal coherence structure (local, pairwise, or global), while maintaining strict *modal independence* from the other blocks.

Special Case: Active Zone Model If $\mathcal{P} = \{X_{\text{dyn}}, X_{\text{stat}}\}$ with:

$$\hat{F}^{(X_{\text{stat}})}_{\text{para}} = 0 \quad \Rightarrow \quad U_{X_{\text{stat}}} = \mathbb{I},$$

then U_N reduces to the *Generalized Non-Coupled Operator*:

$$U_N^{(\text{gen})} = \mathbb{I}_{X_{\text{stat}}} \otimes e^{i\hat{F}_{\text{gen}}|_{X_{\text{dyn}}}}.$$

Definition 2.55 (Blockwise synthesis of $U_\beta = e^{i\hat{F}^{(\beta)}_{\text{para}}}$ via flagged phases)**.** For a block $X_\beta = \{x_{i_1}, \ldots, x_{i_{m_\beta}}\}$ with duality qubits $\mathbf{d}^{(\beta)} := (d_{x_{i_1}}, \ldots, d_{x_{i_{m_\beta}}})$, let

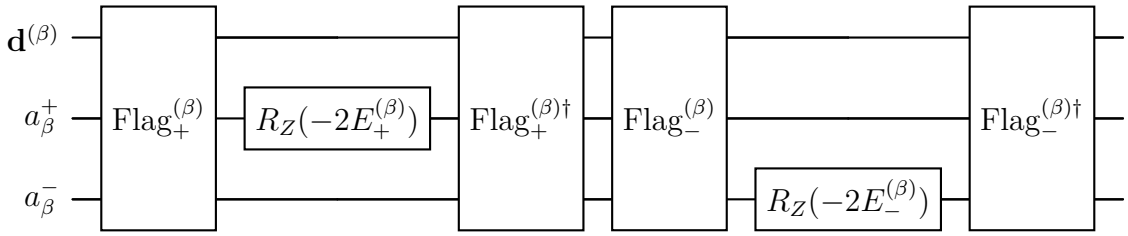
$$\hat{F}^{(\beta)}_{\text{para}} = E^{(\beta)}_+ P^{(X_\beta)}_{\text{para}} + E^{(\beta)}_- P^{(X_\beta)}_{\underbrace{\phantom{\text{antipara}}}_{\text{antipara}}} + \sum_\gamma E^{(\beta)}_\gamma P^{(\beta)}_\gamma.$$

Let $V^{(\beta)}_+$ and $V^{(\beta)}_-$ be the state-preparation unitaries that map a seed $|10\cdots0\rangle$ on $\mathbf{d}^{(\beta)}$ to $|\Psi^{(m_\beta)}_{\text{para}}\rangle$ and $|\widetilde{\Psi}^{(m_\beta)}_{\text{antipara}}\rangle$, respectively (cf. the multipartite synthesis circuits). Define coherent flags using ancillae a^+_β, a^-_β:

$$\text{Flag}^{(\beta)}_+ := V^{(\beta)}_+ \Big(\text{CTRL}_{d_{x_{i_1}}=1} \prod_{j=2}^{m_\beta} \text{CTRL}_{d_{x_{i_j}}=0} \Big) X_{a^+_\beta} V^{(\beta)\dagger}_+,$$

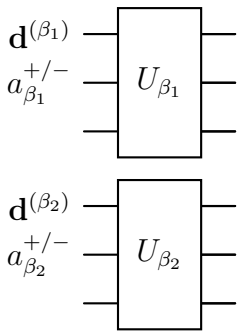
$$\text{Flag}^{(\beta)}_- := V^{(\beta)}_- \Big(\text{CTRL}_{d_{x_{i_1}}=1} \prod_{j=2}^{m_\beta} \text{CTRL}_{d_{x_{i_j}}=0} \Big) X_{a^-_\beta} V^{(\beta)\dagger}_-.$$

Then $U_\beta = e^{i\hat{F}^{(\beta)}_{\text{para}}}$ (up to a global phase on the complementary subspace) is implemented by phase kickback:



Additional spectral components $P^{(\beta)}_\gamma$ are handled by appending analogous flag–phase–uncompute segments with their own ancillae and angles $-2E^{(\beta)}_\gamma$.

Definition 2.56 (Parallel composition: $U^{(\beta)}_N = \bigotimes_{\beta\in\mathcal{P}} U_\beta$)**.** Let $\mathcal{P} = \{X_\beta\}$ be a partition of sites. Since blocks act on disjoint registers, the implementations of U_β commute and may run concurrently. Schematic (two blocks shown, generalization is immediate):



Thus the full gate is realized as a tensor product of the concurrently executed block circuits, in accordance with eq. (2.51).

Remark 2.57 (Active Zone Model (special case))**.** If $X_{\text{stat}} \in \mathcal{P}$ satisfies $\hat{F}_{\text{para}}^{(X_{\text{stat}})} = 0$, the corresponding block circuit is omitted (identity on $\mathbf{d}^{(\text{stat})}$), and only the dynamic block(s) X_{dyn} execute the flag–phase–uncompute sequence, yielding $U_N^{(\text{gen})} = \mathbb{I}_{X_{\text{stat}}} \otimes e^{i\hat{F}_{\text{gen}}|_{X_{\text{dyn}}}}$.

Remark 2.58 (Resources)**.** Depth equals $\max_\beta\{\text{depth}(V_\pm^{(\beta)}) + \text{depth}(n_\beta\text{-controlled Toffoli})\}$, where $n_\beta = |X_\beta|$. Gate count scales additively across blocks; parallel scheduling across β minimizes wall–clock depth due to block independence.

2.2.11 The Zonal Decoupled Unitary Evolution

Definition 2.59 (Zonal Decoupled Unitary Parasymmetric Operator)**.** Let $\mathcal{X}_q^{(n)} = X_{\text{stat}} \cup X_{\text{dyn}}$, with $X_{\text{stat}} \cap X_{\text{dyn}} = \emptyset$, be a bipartition of an n-PQS configuration.

Define:

$$\mathcal{H}_{\text{para}}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes n},$$

$$\mathcal{H}_{\text{stat}} := \bigotimes_{x_i \in X_{\text{stat}}} \mathcal{H}_{(0,1)}^{(x_i)}, \quad \mathcal{H}_{\text{dyn}} := \bigotimes_{x_j \in X_{\text{dyn}}} \mathcal{H}_{(0,1)}^{(x_j)}.$$

Let the generalized parasymmetric generator over X_{dyn} be:

$$\hat{F}_{\text{gen}}|_{X_{\text{dyn}}} := \lambda_L \hat{F}_{\text{para}}^{(\text{local})}|_{X_{\text{dyn}}} + \lambda_P \hat{F}_{\text{para}}^{(\text{pair})}|_{X_{\text{dyn}}} + \lambda_G \hat{F}_{\text{para}}^{(n)}|_{X_{\text{dyn}}},$$

where $\lambda_L, \lambda_P, \lambda_G \in \mathbb{R}$ are coupling constants.

Then the *Zonal Decoupled Unitary Parasymmetric Operator* is:

$$\boxed{U_N^{(\text{zonal})} := \mathbb{I}_{X_{\text{stat}}} \otimes e^{i\hat{F}_{\text{gen}}|_{X_{\text{dyn}}}}.} \tag{2.52}$$

Properties

1. **Partial Evolution:** Only the PQSs in X_{dyn} evolve; those in X_{stat} remain static.
2. **Modal Factorization:** The total operator factorizes:
$$U_N^{(\text{zonal})} \in \mathcal{U}(\mathcal{H}_{\text{stat}}) \otimes \mathcal{U}(\mathcal{H}_{\text{dyn}}).$$
3. **Internal Coherence Richness:** Dynamics within X_{dyn} can include local, pairwise, or global coherence modes depending on the structure of $\hat{F}_{\text{gen}}$.

Interpretation. This operator models a localized parasymmetric dynamic of high structural complexity while maintaining full decoupling from the external modal domain. It formalizes *modular evolution* in the IQR.

Definition 2.60 (Circuit synthesis of $U_N^{(\mathrm{zonal})} = \mathbb{I}_{X_{\mathrm{stat}}} \otimes e^{i\hat{F}_{\mathrm{gen}}|_{X_{\mathrm{dyn}}}}$)**.** Let

$$\hat{F}_{\mathrm{gen}}|_{X_{\mathrm{dyn}}} := \lambda_L\, \hat{F}^{(\mathrm{local})}_{\mathrm{para}}|_{X_{\mathrm{dyn}}} + \lambda_P\, \hat{F}^{(\mathrm{pair})}_{\mathrm{para}}|_{X_{\mathrm{dyn}}} + \lambda_G\, \hat{F}^{(n)}_{\mathrm{para}}|_{X_{\mathrm{dyn}}}.$$

The overall circuit leaves all d_x with $x \in X_{\mathrm{stat}}$ as bare wires (identity), and acts only on d_x with $x \in X_{\mathrm{dyn}}$. When the three terms do not commute, use a Trotter–Suzuki product with $r \in \mathbb{N}$ steps:

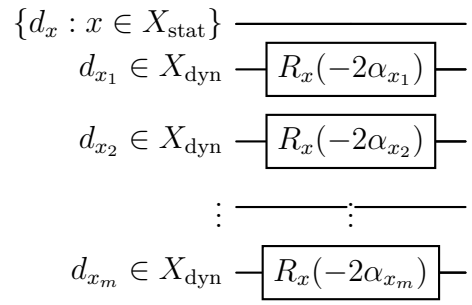
$$U_N^{(\mathrm{zonal})} \;\approx\; \mathbb{I}_{X_{\mathrm{stat}}} \otimes \left[e^{i\frac{\lambda_L}{r}\hat{F}^{(\mathrm{local})}_{\mathrm{para}}}\; e^{i\frac{\lambda_P}{r}\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}}\; e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\mathrm{para}}} \right]^r,$$

or the symmetric second-order variant by inserting the terms in palindromic order.

Definition 2.61 (Local segment $e^{i\frac{\lambda_L}{r}\hat{F}^{(\mathrm{local})}_{\mathrm{para}}}$)**.** For each $x \in X_{\mathrm{dyn}}$, write the local contribution as $h_x\,(P^{(x)}_{\mathrm{para}} - P^{(x)}_{\mathrm{antipara}}) = h_x\, X_{d_x}$ on $\mathcal{H}^{(x)}_{(0,1)}$. Implement $e^{i\frac{\lambda_L}{r}h_x X}$ as a one-qubit rotation

$$e^{i\frac{\lambda_L}{r}h_x X} \;=\; R_x\Big(-2\tfrac{\lambda_L}{r}h_x\Big),$$

applied in parallel to all d_x in X_{dyn}:

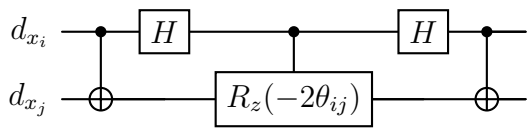


$$\alpha_x := \tfrac{\lambda_L}{r}h_x.$$

Definition 2.62 (Pair segment $e^{i\frac{\lambda_P}{r}\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}}$)**.** For each interacting pair $(x_i, x_j) \subset X_{\mathrm{dyn}}$ with coupling J_{ij}, the two-qubit contribution $J_{ij}\Big(P^{(x_i x_j)}_{\mathrm{para}} - P^{(x_i x_j)}_{\mathrm{antipara}}\Big)$ acts as $+1$ on $|\Psi^+\rangle$ and -1 on $|\Psi^-\rangle$. Using the inverse Bell map $(\mathrm{CNOT}(i \to j);\, H_i)$ that sends $|\Psi^\pm\rangle \mapsto |1\,0/1\rangle$, implement

$$e^{i\theta_{ij}\,(P_{\Psi^+} - P_{\Psi^-})}, \qquad \theta_{ij} := \tfrac{\lambda_P}{r}J_{ij},$$

by a controlled-R_z on d_{x_j} conditioned on d_{x_i}=1, flanked by the Bell uncompute/compute:



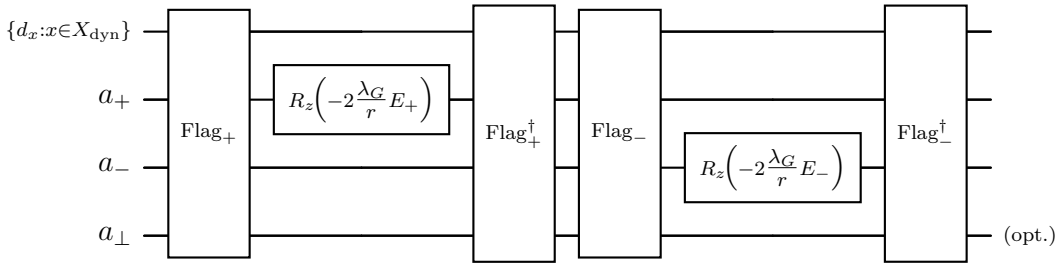
Apply these two-qubit segments for all (i, j) in the chosen interaction set (scheduling to respect hardware connectivity if needed).

Definition 2.63 (Global segment $e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\mathrm{para}}\Big|_{X_{\mathrm{dyn}}}}$)**.** Let $m := |X_{\mathrm{dyn}}|$, and let V_+ and V_- be the m-qubit state-preparation unitaries mapping a fixed seed to $|\Psi^{(m)}_{\mathrm{para}}\rangle$ and $|\widetilde{\Psi}^{(m)}_{\mathrm{antipara}}\rangle$, respectively.

With ancillae a_+, a_- initialized to $|0\rangle$, define coherent flags

$$\mathrm{Flag}_+ := V_+\Big(\,\mathrm{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{m}\mathrm{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_+}\,V_+^\dagger,$$
$$\mathrm{Flag}_- := V_-\Big(\,\mathrm{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{m}\mathrm{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_-}\,V_-^\dagger.$$

Assume that $\hat{F}^{(n)}_{\mathrm{para}}\big|_{X_{\mathrm{dyn}}}$ has eigenvalues E_+, E_- on these two rank-1 subspaces, and $E_\perp$ on the orthogonal complement. Apply phase-kickback with angles scaled by λ_G/r:



(An overall phase $e^{\,i(\lambda_G/r)E_\perp}$ on the orthogonal subspace may be ignored or realised similarly if needed.)

Definition 2.64 (One Trotter step and repetition)**.** A single step for X_{dyn} concatenates Definitions 2.61 to 2.63:

$$\boxed{\mathcal{S}_{\mathrm{dyn}} \;:=\; e^{\,i\frac{\lambda_L}{r}\hat{F}^{(\mathrm{local})}_{\mathrm{para}}}\;e^{\,i\frac{\lambda_P}{r}\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}}\;e^{\,i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\mathrm{para}}}}\quad\Rightarrow\quad U_N^{(\mathrm{zonal})}\approx\mathbb{I}_{X_{\mathrm{stat}}}\otimes\Big(\mathcal{S}_{\mathrm{dyn}}\Big)^r.$$

Static-zone wires (all d_x with $x\in X_{\mathrm{stat}}$) remain identity throughout:

Remark 2.65 (Resources)**.** Per Trotter step: (i) $|X_{\mathrm{dyn}}|$ single-qubit R_x gates (local); (ii) one Bell-uncompute + one CR_z + one Bell-recompute per interacting pair (pair term); (iii) two $|X_{\mathrm{dyn}}|$-controlled flags and two single-qubit R_z rotations (global). Depth scales as $O(|X_{\mathrm{dyn}}|)$ with nearest-neighbour scheduling; static-zone depth is zero by construction.

2.2.12 The Generalized Composite Decoupled Parasymmetric Evolution Operator

Definition 2.66 (Generalized Composite Parasymmetric Evolution Operator)**.** Let $\mathcal{X}_q^{(n)} = \{\mathfrak{B}_{x_1},\ldots,\mathfrak{B}_{x_n}\}$ be a configuration of n Primordial Quantum Singularities, with parasymmetric modal subspace:

$$\mathcal{H}^{(n)}_{\mathrm{para}} := \bigotimes_{i=1}^{n}\mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Let $\mathcal{P} = \{X_L, X_P, X_G\}$ be a disjoint partition of the configuration into blocks corresponding to:

- X_L: sites evolving under **local** coherence dynamics,
- X_P: sites evolving under **pairwise** parasymmetric entanglement,
- X_G: sites evolving under **global modal-class** coherence dynamics.

Assign to each block a Hermitian parasymmetric generator:
(i) Local Coherence Generator:

$$\hat{F}^{(L)}_{\text{para}} := \sum_{x_i \in X_L} \left(P^{(x_i)}_{\text{para}} - P^{(x_i)}_{\text{antipara}} \right).$$

(ii) Pairwise Entanglement Generator:

$$\hat{F}^{(P)}_{\text{para}} := \sum_{i<j \in X_P} J_{ij} \left(P^{(x_i x_j)}_{\text{para}} - P^{(x_i x_j)}_{\text{antipara}} \right), \quad J_{ij} = J_{ji} \in \mathbb{R}.$$

(iii) Global Modal-Class Generator:

$$\hat{F}^{(G)}_{\text{para}} := E_+ P^{(X_G)}_{\text{para}} + E_- P^{(X_G)}_{\widetilde{\text{antipara}}} + \sum_{\gamma} E_\gamma P_\gamma.$$

Then the corresponding blockwise unitary evolutions are:

$$U_L := e^{i\hat{F}^{(L)}_{\text{para}}}, \quad U_P := e^{i\hat{F}^{(P)}_{\text{para}}}, \quad U_G := e^{i\hat{F}^{(G)}_{\text{para}}}.$$

The *Generalized Composite Parasymmetric Evolution Operator* is then defined as:

$$\boxed{U^{(\odot)}_N := U_L \otimes U_P \otimes U_G = \bigotimes_{\beta \in \{L,P,G\}} e^{i\hat{F}^{(\beta)}_{\text{para}}}.} \tag{2.53}$$

Interpretation. This operator unifies local, pairwise, and global parasymmetric dynamics within a single decoupled configuration. Each subregion evolves autonomously under its assigned coherence structure, yet all contribute to the overall parasymmetric evolution of the system.

Definition 2.67 (Blockwise circuits for $U^{(\odot)}_N = U_L \otimes U_P \otimes U_G$)**.** Each factor acts on disjoint registers and can be executed in parallel.

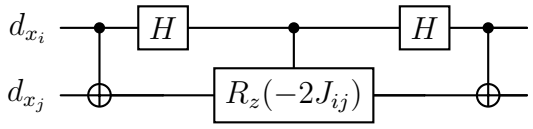
(i) Local coherence block $U_L = e^{i\hat{F}^{(L)}_{\text{para}}}$ Using $P^{(x)}_{\text{para}} = \frac{1}{2}(\mathbb{I} + X_{d_x})$ and $P^{(x)}_{\text{antipara}} = \frac{1}{2}(\mathbb{I} - X_{d_x})$ on $\mathcal{H}^{(x)}_{(0,1)}$,

$$\hat{F}^{(L)}_{\text{para}} = \sum_{x \in X_L} \left(P^{(x)}_{\text{para}} - P^{(x)}_{\text{antipara}} \right) = \sum_{x \in X_L} X_{d_x} \quad \Rightarrow \quad U_L = \prod_{x \in X_L} e^{iX_{d_x}} = \prod_{x \in X_L} R_x(-2).$$

Circuit (all rotations in parallel):

$\{d_x : x \in X_L\}$ —$\boxed{R_x(-2)}$—

(ii) Pairwise entanglement block $U_P = e^{i\hat{F}^{(P)}_{\text{para}}}$ For each $(i,j) \in X_P$ with coupling J_{ij}, $\hat{F}^{(P)}_{\text{para}} \ni J_{ij}\left(P^{(x_i x_j)}_{\text{para}} - P^{(x_i x_j)}_{\text{antipara}}\right)$, which phases $|\Psi^+\rangle$ by $+J_{ij}$ and $|\Psi^-\rangle$ by $-J_{ij}$. Implement via inverse Bell map (CNOT $i \to j$, then H on i), a controlled R_z, and recompute:



Apply one such segment per interacting pair (schedule per hardware connectivity).

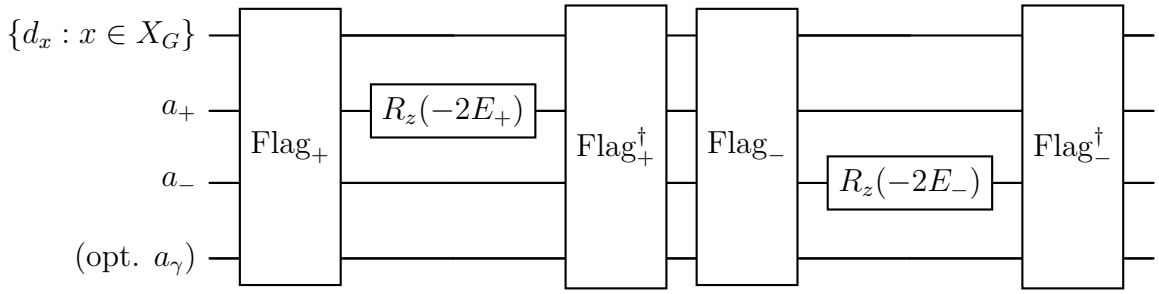
(iii) Global modal-class block $U_G = e^{i\hat{F}^{(G)}_{\text{para}}}$ Let $m := |X_G|$ and let V_+, V_- be the m-qubit preparation unitaries for $|\Psi^{(m)}_{\text{para}}\rangle$ and $|\widetilde{\Psi}^{(m)}_{\text{antipara}}\rangle$ (see multipartite synthesis circuits). With ancillae a_+, a_-:

$$\begin{aligned}
\text{Flag}_+ &:= V_+\Big(\text{CTRL}_{d_{x_1}=1} \prod_{\ell=2}^{m} \text{CTRL}_{d_{x_\ell}=0}\Big) \quad X_{a_+}\, V_+^\dagger, \\
\text{Flag}_- &:= V_-\Big(\text{CTRL}_{d_{x_1}=1} \prod_{\ell=2}^{m} \text{CTRL}_{d_{x_\ell}=0}\Big) \quad X_{a_-}\, V_-^\dagger.
\end{aligned}$$

If

$$\hat{F}^{(G)}_{\text{para}} = E_+ P^{(X_G)}_{\text{para}} + E_- P^{(X_G)}_{\widetilde{\text{antipara}}} + \sum_\gamma E_\gamma P_\gamma$$

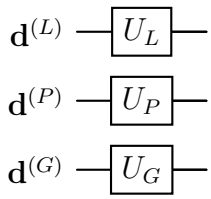
use phase kickback on the flags (extend with additional flags for the P_γ terms if needed):



Parallel composition Since the three blocks act on disjoint registers $\mathbf{d}^{(L)}$, $\mathbf{d}^{(P)}$, $\mathbf{d}^{(G)}$, their circuits commute and can run concurrently, realizing exactly

$$U_N^{(\odot)} \;=\; U_L \otimes U_P \otimes U_G \quad \text{as in eq. (2.53)}.$$

A schematic layout:



Remark 2.68 (Resources)**.** Local: $|X_L|$ single-qubit R_x gates (depth 1 in parallel). Pairwise: per interacting pair, one CNOT–H uncompute, one controlled R_z, and one recompute (depth $O(1)$ per pair; schedule by edge coloring). Global: two $|X_G|$-controlled flags plus two single-qubit R_z rotations (log-depth with ancillae using standard decompositions). Overall depth is the maximum of the three block depths due to parallel execution.

Remark 2.69 (Operational effect of the composite parasymmetric evolution)**.** The unitary in eq. (2.53), $U_N^{(\odot)} = U_L \otimes U_P \otimes U_G$, acts independently on three disjoint modal blocks and therefore factors its action across registers:

$$\begin{aligned} U_L &= \exp\Big(i \sum_{x\in X_L} \Big[P^{(x)}_{\text{para}} - P^{(x)}_{\text{antipara}}\Big]\Big), \\ U_P &= \exp\Big(i \sum_{\substack{i<j \\ i,j\in X_P}} J_{ij} \Big[P^{(x_i x_j)}_{\text{para}} - P^{(x_i x_j)}_{\text{antipara}}\Big]\Big), \\ U_G &= \exp\Big(i\hat{F}^{(G)}_{\text{para}}\Big). \end{aligned}$$

- **Local block U_L (single-site coherence).** On each duality qubit d_x with $x \in X_L$, $P^{(x)}_{\text{para}} - P^{(x)}_{\text{antipara}} = X_{d_x}$ in the $(0,1)$-sector, hence

$$U_L = \prod_{x\in X_L} e^{iX_{d_x}} = \prod_{x\in X_L} R_x(-2).$$

  It performs an x-axis rotation that coherently mixes $|\mathring{\mathbf{0}}\rangle_x$ and $|\mathring{\mathbf{1}}\rangle_x$ without leaving $\mathcal{H}^{(x)}_{(0,1)}$.

- **Pair block U_P (two-site exchange/entanglement).** Using $P^{(x_i x_j)}_{\text{para}} - P^{(x_i x_j)}_{\text{antipara}} = \frac{1}{2}\big(X_{d_{x_i}} X_{d_{x_j}} + Y_{d_{x_i}} Y_{d_{x_j}}\big)$, each pair evolution is an *XY-exchange* (partial iSWAP–type) gate:

$$U_{ij} := \exp\Big(i\tfrac{J_{ij}}{2}(X_iX_j + Y_iY_j)\Big), \quad \begin{aligned} U_{ij}\,|01\rangle &= \cos\tfrac{J_{ij}}{2}\;|01\rangle + i\sin\tfrac{J_{ij}}{2}\;|10\rangle\,, \\ U_{ij}\,|10\rangle &= \cos\tfrac{J_{ij}}{2}\;|10\rangle + i\sin\tfrac{J_{ij}}{2}\;|01\rangle\,, \\ U_{ij}\,|00\rangle &= |00\rangle\,, \quad U_{ij}\,|11\rangle = |11\rangle\,, \end{aligned}$$

  equivalently phasing the Bell states as $|\Psi^{\pm}\rangle \mapsto e^{\pm iJ_{ij}}\,|\Psi^{\pm}\rangle$ while leaving $|\Phi^{\pm}\rangle$ invariant.

- **Global block U_G (modal-class phases).** On the $m := |X_G|$-site duality register,

$$\hat{F}^{(G)}_{\text{para}} = E_+ P^{(X_G)}_{\text{para}} + E_- P^{(X_G)}_{\widetilde{\text{antipara}}} + \sum_\gamma E_\gamma P_\gamma,$$

  so U_G is block-diagonal: it applies eigenphases e^{iE_+} and e^{iE_-} to the two rank-1 subspaces $\text{span}\{|\Psi^{(m)}_{\text{para}}\rangle\}$ and $\text{span}\{|\widetilde{\Psi}^{(m)}_{\text{antipara}}\rangle\}$, and e^{iE_γ} on each orthogonal component P_γ.

In summary: $U_N^{(\odot)}$ performs (i) local x-axis rotations on X_L; (ii) XY-exchange entangling evolutions on specified pairs in X_P; and (iii) modal-class phase rotations on the distinguished multipartite subspace in X_G. Because the blocks act on disjoint tensor factors, these transformations commute and the total evolution is the tensor product of the three independent processes.

2.2.13 The $\hat{\sigma}$ Global Coupled Unitary Evolution

Definition 2.70 (Global Coupled Unitary Parasymmetric Operator)**.** Suppose that there are n Primordial Quantum Singularities $\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}$, with parasymmetric modal subspace:

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Define the Hermitian parasymmetric generator:

$$\hat{F}_{\text{para}} := \sum_{i,j=1}^{n} J_{ij} \left(\hat{\sigma}^{(+)}_{x_i} \hat{\sigma}^{(-)}_{x_j} + \hat{\sigma}^{(+)}_{x_j} \hat{\sigma}^{(-)}_{x_i} \right), \quad J_{ij} = J_{ji} \in \mathbb{R},$$

where $\hat{\sigma}^{(+)}_{x_i}$ and $\hat{\sigma}^{(-)}_{x_i}$ are the modal raising and lowering operators acting on $\mathcal{H}^{(x_i)}_{(0,1)}$.

Then the $\hat{\sigma}$ *Global Coupled Unitary Parasymmetric Operator* is defined as:

$$\boxed{U^{(\hat{\sigma})}_{G} := e^{i\hat{F}_{\text{para}}}.} \tag{2.54}$$

Properties

1. **Entangling Evolution:** The operator U_G enables coherent interactions among all PQSs in $\mathcal{X}^{(n)}_q$, without blockwise separability.
2. **Graph-Theoretic Coupling:** The interaction pattern is determined by the matrix J_{ij}, which encodes a weighted undirected graph of modal connectivity.
3. **Non-Factorizability:** Unlike the decoupled cases, U_G generally cannot be written as a tensor product of operators acting on strict subregions.

Interpretation. This operator governs fully global modal evolution, wherein parasymmetric coherence may propagate, interfere, and self-organize across the entire configuration space. It instantiates the synthetic logic of Parasymmetry—fusing local modes into dynamically entangled dialectical wholes.

Definition 2.71 (Exchange form of the generator)**.** Using $\hat{\sigma}^{(+)} = \frac{1}{2}(X + iY)$ and $\hat{\sigma}^{(-)} = \frac{1}{2}(X - iY)$ on each duality qubit,

$$\hat{\sigma}^{(+)}_{x_i} \hat{\sigma}^{(-)}_{x_j} + \hat{\sigma}^{(+)}_{x_j} \hat{\sigma}^{(-)}_{x_i} \;=\; \tfrac{1}{2}\Big(X_{d_{x_i}} X_{d_{x_j}} + Y_{d_{x_i}} Y_{d_{x_j}} \Big).$$

Absorbing any summation symmetry into the couplings, write

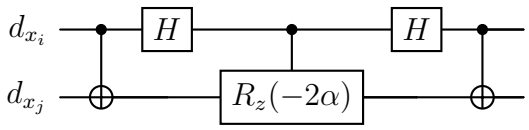
$$\hat{F}_{\text{para}} = \sum_{i<j} \theta_{ij} \, \frac{X_{d_{x_i}} X_{d_{x_j}} + Y_{d_{x_i}} Y_{d_{x_j}}}{2}, \qquad U^{(\hat{\sigma})}_{G} = e^{\,i\hat{F}_{\text{para}}} = \prod_{i<j} \exp\Big(i \, \tfrac{\theta_{ij}}{2} \, (X_i X_j + Y_i Y_j) \Big),$$

where θ_{ij} equals J_{ij} up to a possible factor of 2 depending on the double-sum convention.

Definition 2.72 (Primitive XY–exchange gate (iSWAP$^\alpha$ form))**.** For a pair (i, j) define

$$U_{ij}(\alpha) \;:=\; \exp\!\Big(i\,\tfrac{\alpha}{2}\,(X_iX_j + Y_iY_j)\Big) \quad\Longleftrightarrow\quad \begin{aligned} U_{ij}(\alpha)\,|01\rangle &= \cos\tfrac{\alpha}{2}\;|01\rangle + i\sin\tfrac{\alpha}{2}\;|10\rangle\,,\\ U_{ij}(\alpha)\,|10\rangle &= \cos\tfrac{\alpha}{2}\;|10\rangle + i\sin\tfrac{\alpha}{2}\;|01\rangle\,,\\ U_{ij}(\alpha)\,|00\rangle &= |00\rangle\,, \quad U_{ij}(\alpha)\,|11\rangle = |11\rangle\,. \end{aligned}$$

A convenient decomposition uses an inverse Bell map (CNOT then H) to diagonalize the $\{|\Psi^\pm\rangle\}$ subspace, apply a controlled phase, and recompute:



This realizes $U_{ij}(\alpha)$ since $|\Psi^\pm\rangle$ pick phases $e^{\pm i\alpha}$ and $|\Phi^\pm\rangle$ remain invariant.

Definition 2.73 (Trotterized synthesis for arbitrary coupling graph)**.** Let $G = (V, E)$ with $V = \{x_1, \ldots, x_n\}$ and weighted edges $(i, j) \in E$ carrying angles $\alpha_{ij} = \theta_{ij}$. A first-order Trotter step at time slice $1/r$ is

$$\mathcal{S} \;:=\; \prod_{(i,j)\in E} U_{ij}\Big(\tfrac{\alpha_{ij}}{r}\Big), \qquad U_G^{(\hat\sigma)} \;\approx\; \big(\mathcal{S}\big)^r.$$

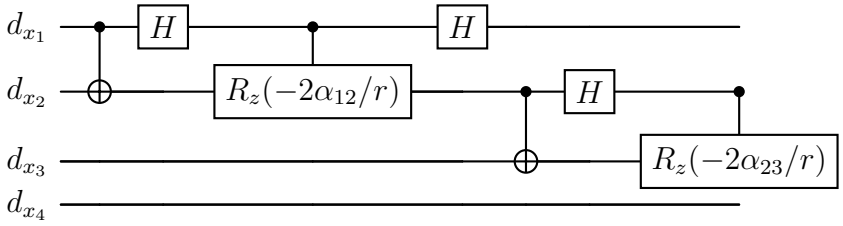
To parallelize, color edges into disjoint matchings $E = E_1 \cup \cdots \cup E_c$ and apply all U_{ij} in each E_ℓ simultaneously:

$$\mathcal{S} \;=\; \prod_{\ell=1}^{c}\; \prod_{(i,j)\in E_\ell}^{\text{in parallel}} U_{ij}\Big(\tfrac{\alpha_{ij}}{r}\Big).$$

Each U_{ij} uses the two–CNOT pattern of Definition 2.72.

Remark 2.74 (Nearest-neighbour chains and all-to-all cases)**.** For a 1D chain with uniform θ, depth per Trotter step is 2 (odd bonds in parallel, then even bonds), each bond using two CNOTs and one R_z. For dense all-to-all J_{ij}, use a SWAP network to expose each pair once per layer; total two-qubit depth $O(n)$ per Trotter step with the same U_{ij} primitive.

Definition 2.75 (Global coupled parasymmetric circuit (schematic one-step))**.** One Trotter step for a chain $x_1 - x_2 - \cdots - x_n$:



(Continue the odd-bond layer, then the even-bond layer, using the same two–CNOT + R_z sandwich per adjacent pair.)

Remark 2.76 (Consistency with eq. (2.54))**.** Combining Definitions 2.71 to 2.73 yields a concrete, hardware-ready compilation of $U_G^{(\hat{\sigma})} = \exp\Big(i \sum_{i,j} J_{ij}[\hat{\sigma}_i^{(+)}\hat{\sigma}_j^{(-)} + \hat{\sigma}_j^{(+)}\hat{\sigma}_i^{(-)}]\Big)$, with angles α_{ij} chosen to absorb any factor-of-two from the summation convention.

Remark 2.77 (Operational effect of the global coupled parasymmetric gate)**.** The unitary $U_G^{(\hat{\sigma})} = \exp\Big(i\hat{F}_{\text{para}}\Big)$ with

$$\hat{F}_{\text{para}} = \sum_{i,j} J_{ij}\Big(\hat{\sigma}_{x_i}^{(+)}\hat{\sigma}_{x_j}^{(-)} + \hat{\sigma}_{x_j}^{(+)}\hat{\sigma}_{x_i}^{(-)}\Big) = \sum_{i<j} \frac{\theta_{ij}}{2}\Big(X_iX_j + Y_iY_j\Big)$$

is an XY–exchange evolution that *coherently transports* the single "antisymmetry excitation" across the coupling graph defined by $J = (J_{ij})$, while preserving the total excitation number. Let

$$\hat{N} := \sum_{k=1}^{n} \frac{\mathbb{I} - Z_k}{2} \quad \Rightarrow \quad [\hat{N}, \hat{F}_{\text{para}}] = 0,$$

so $U_G^{(\hat{\sigma})}$ acts block-diagonally on the Hamming-weight sectors.

Pair action (two sites). On a coupled pair (i, j),

$$U_{ij}(\alpha) := \exp\Big(i\frac{\alpha}{2}(X_iX_j + Y_iY_j)\Big): \quad \begin{aligned} |01\rangle &\mapsto \cos\tfrac{\alpha}{2}\,|01\rangle + i\sin\tfrac{\alpha}{2}\,|10\rangle\,, \\ |10\rangle &\mapsto \cos\tfrac{\alpha}{2}\,|10\rangle + i\sin\tfrac{\alpha}{2}\,|01\rangle\,, \\ |00\rangle &\mapsto |00\rangle\,, \quad |11\rangle \mapsto |11\rangle\,. \end{aligned}$$

Equivalently, in the Bell basis it applies phases to the exchange states $|\Psi^{\pm}\rangle = \frac{1}{\sqrt{2}}(|01\rangle \pm |10\rangle)$:

$$|\Psi^{\pm}\rangle \mapsto e^{\pm i\alpha}\,|\Psi^{\pm}\rangle\,, \qquad |\Phi^{\pm}\rangle \text{ invariant.}$$

Thus it is an iSWAP$^{\alpha}$-type entangling gate (iSWAP at $\alpha = \frac{\pi}{2}$, SWAP up to phases at $\alpha = \pi$).

Single-excitation sector (global action). Let $\{\,|\phi_k\rangle\,\}_{k=1}^{n}$ denote the basis with a sole antisymmetry at site x_k (i.e. $|\phi_k\rangle = |0\rangle^{\otimes(k-1)}\,|1\rangle\,|0\rangle^{\otimes(n-k)}$ in the duality register). Restricted to this sector,

$$U_G^{(\hat{\sigma})}(t)\;|\phi_k\rangle = \sum_{j=1}^{n} \Big[e^{\,itJ}\Big]_{jk}\;|\phi_j\rangle\,,$$

so the excitation executes a continuous-time quantum walk on the weighted graph with adjacency J. Amplitudes *hop* along edges with rates set by J_{ij}, generating long-range parasymmetric coherence.

Multiple excitations. On higher Hamming-weight sectors, $U_G^{(\hat{\sigma})}$ enacts number-conserving XY dynamics: excitations exchange their positions via the same pairwise mechanism, producing genuinely multipartite entanglement while never leaving the parasymmetric modal subspace.

Summary. $U_G^{(\hat{\sigma})}$ is a globally coupled, excitation-preserving exchange evolution that: (i) mixes $|01\rangle \leftrightarrow |10\rangle$ coherently on each coupled edge; (ii) realizes graph-wide transport and interference of parasymmetric amplitude in the single-excitation manifold; and (iii) yields entangling XY dynamics in multi-excitation manifolds, all determined by the coupling matrix J.

2.2.14 The Global Composite λ Coupled Unitary Evolution

Definition 2.78 (Global Composite Coupled Unitary Parasymmetric Operator)**.** Let $\mathcal{X}_q^{(n)} = \{\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}\}$ be a configuration of n Primordial Quantum Singularities (PQSs), and define the parasymmetric modal Hilbert space:

$$\mathcal{H}_{\text{para}}^{(n)} := \bigotimes_{i=1}^{n} \mathcal{H}_{(0,1)}^{(x_i)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Let the total Hermitian parasymmetric generator be a weighted combination of local, pairwise, and global terms:

$$\hat{F}_{\text{para}} := \lambda_L \hat{F}_{\text{para}}^{(\text{local})} + \lambda_P \hat{F}_{\text{para}}^{(\text{pair})} + \lambda_G \hat{F}_{\text{para}}^{(n)},$$

where:

- $\hat{F}_{\text{para}}^{(\text{local})} = \sum_i \tau_z^{(x_i)}$, the local coherence generator;
- $\hat{F}_{\text{para}}^{(\text{pair})} = \sum_{i<j} J_{ij}(P_{\text{para}}^{(x_i x_j)} - P_{\text{antipara}}^{(x_i x_j)})$, the pairwise entanglement generator;
- $\hat{F}_{\text{para}}^{(n)} = E_+ P_{\text{para}}^{(x_1 \ldots x_n)} + E_- P_{\underbrace{}_{\text{antipara}}}^{(x_1 \ldots x_n)} + \sum_\gamma E_\gamma P_\gamma$, the global modal-class generator;
- and $\lambda_L, \lambda_P, \lambda_G \in \mathbb{R}$ are tunable real parameters.

Then the λ *Global Coupled Unitary Parasymmetric Operator* is defined as:

$$\boxed{U_G^{(\lambda)} := \exp\left(i\left[\lambda_L \hat{F}_{\text{para}}^{(\text{local})} + \lambda_P \hat{F}_{\text{para}}^{(\text{pair})} + \lambda_G \hat{F}_{\text{para}}^{(n)}\right]\right).} \tag{2.55}$$

Interpretation. This operator generates a coherent evolution across the entire PQS configuration, unifying:

- **Local parasymmetry** at each site,
- **Pairwise entanglement** between PQSs,
- **Global modal synthesis/dissonance** through modal-class structure.

It represents the most general *entanglement-generating and coherence-synthesizing* evolution allowed within the parasymmetric sector.

Definition 2.79 (One Trotter step for $U_G^{(\lambda)}$)**.** For non-commuting local/pair/global terms, use a first-order Trotter product with $r \in \mathbb{N}$ steps:

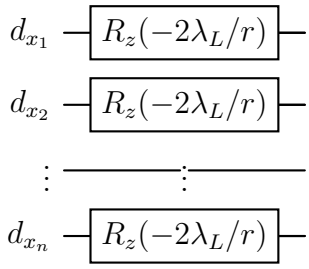
$$U_G^{(\lambda)} \;\approx\; \left[e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}} \; e^{i\frac{\lambda_P}{r}\hat{F}^{(\text{pair})}_{\text{para}}} \; e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\text{para}}} \right]^r,$$

or the symmetric second-order formula by palindromic ordering. One Trotter step decomposes into the three segments below.

Definition 2.80 (Local segment $e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}}$)**.** With $\hat{F}^{(\text{local})}_{\text{para}} = \sum_x \tau_z^{(x)}$ and $\tau_z^{(x)} \equiv Z_{d_x}$ on $\mathcal{H}^{(x)}_{(0,1)}$,

$$e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}} = \prod_x e^{i\frac{\lambda_L}{r}Z_{d_x}} = \prod_x R_z\Big(-2\tfrac{\lambda_L}{r}\Big)_{d_x}.$$

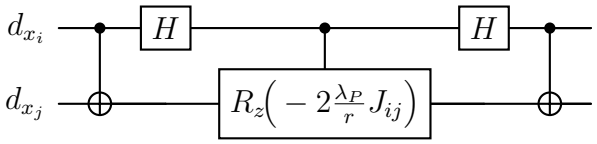
Parallel single-qubit R_z rotations on all duality qubits:



Definition 2.81 (Pairwise segment $e^{i\frac{\lambda_P}{r}\hat{F}^{(\text{pair})}_{\text{para}}}$)**.** Using $P^{(x_i x_j)}_{\text{para}} - P^{(x_i x_j)}_{\text{antipara}} = \frac{1}{2}(X_iX_j + Y_iY_j)$ on duality qubits (d_{x_i}, d_{x_j}), each coupled pair (i,j) evolves by the XY exchange

$$U_{ij}\Big(\tfrac{\lambda_P}{r}J_{ij}\Big) = \exp\Big(i\,\tfrac{\lambda_P}{r}\,\tfrac{J_{ij}}{2}(X_iX_j + Y_iY_j)\Big).$$

Decompose via Bell uncompute (CNOT, then H), a controlled R_z, and recompute:



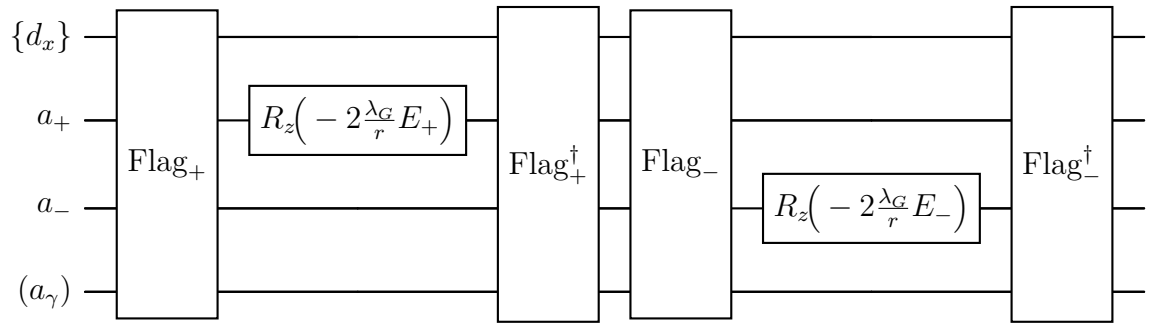
Apply one such block for every interacting (i,j); schedule by edge-coloring to parallelize disjoint pairs.

Definition 2.82 (Global segment $e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\text{para}}}$)**.** Let V_+ and V_- prepare the rank-1 eigenstates $|\Psi^{(n)}_{\text{para}}\rangle$ and $|\widetilde{\Psi}^{(n)}_{\text{antipara}}\rangle$ from a fixed seed (cf. Definitions 2.33 and 2.48). With ancillae a_+, a_- initialized in $|0\rangle$, define coherent flags

$$\text{Flag}_+ := V_+\Big(\,\text{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{n}\text{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_+}\,V_+^\dagger,$$

$$\text{Flag}_- := V_-\Big(\,\text{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{n}\text{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_-}\,V_-^\dagger.$$

Phase-kickback implements the eigenphases of $\hat{F}^{(n)}_{\text{para}} = E_+ P^{(x_1 \dots x_n)}_{\text{para}} + E_- P^{(x_1 \dots x_n)}_{\widetilde{\text{antipara}}} + \sum_\gamma E_\gamma P_\gamma$:



(Additional one-dimensional P_γ sectors, if used, are handled by analogous flag–phase–uncompute blocks.)

Definition 2.83 (One composite step and repetition)**.** A single Trotter step is the concatenation

$$\boxed{\mathcal{S}_\lambda \;:=\; e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}}\; e^{i\frac{\lambda_P}{r}\hat{F}^{(\text{pair})}_{\text{para}}}\; e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\text{para}}}} \quad \Rightarrow \quad U_G^{(\lambda)} \;\approx\; \Big(\mathcal{S}_\lambda\Big)^r,$$

with a symmetric palindromic ordering available for second-order accuracy. Local R_z gates run fully in parallel; pair segments parallelize over disjoint pairs; the two global flags commute (orthogonal projectors), so their phase segments may be swapped.

Remark 2.84 (Resource sketch)**.** Per Trotter step: n single-qubit R_z (local); for each coupled pair, two CNOTs + one R_z (pair); and two n-controlled flags plus two ancilla R_z (global), with optional extra flags for $\{P_\gamma\}$. Depth scales with the edge-coloring number of the pair graph and with the decomposition depth of the multi-controlled Toffoli used in the flags.

2.2.15 The Unified Global Coupled Unitary Evolution

Definition 2.85 (Unified Global Coupled Parasymmetric Operator)**.** Suppose that

$$\mathcal{X}_q^{(n)} = \{\mathfrak{B}_{x_1}, \dots, \mathfrak{B}_{x_n}\}$$

is a configuration of n Primordial Quantum Singularities (PQSs), with parasymmetric modal subspace:

$$\mathcal{H}^{(n)}_{\text{para}} := \bigotimes_{i=1}^{n} \mathcal{H}^{(x_i)}_{(0,1)} \cong (\mathbb{C}^2)^{\otimes n}.$$

Define the *unified Hermitian parasymmetric generator* as:

$$\hat{F}^{(\odot)}_{\text{para}} := \lambda_L \hat{F}^{(\text{local})}_{\text{para}} + \lambda_P \hat{F}^{(\text{pair})}_{\text{para}} + \lambda_G \hat{F}^{(n)}_{\text{para}} + \lambda_X \sum_{i,j=1}^{n} J_{ij} \left(\hat{\sigma}^{(+)}_{x_i}\hat{\sigma}^{(-)}_{x_j} + \hat{\sigma}^{(+)}_{x_j}\hat{\sigma}^{(-)}_{x_i}\right),$$

where:

- $\hat{F}^{(\text{local})}_{\text{para}}$ is the local coherence generator;
- $\hat{F}^{(\text{pair})}_{\text{para}}$ is the pairwise parasymmetric projector generator;
- $\hat{F}^{(n)}_{\text{para}}$ is the global modal-class generator;
- $\hat{\sigma}^{(\pm)}_{x_i}$ are the modal ladder operators on site x_i;
- $J_{ij} \in \mathbb{R}$, with $J_{ij} = J_{ji}$, defines a symmetric coupling matrix;
- $\lambda_L, \lambda_P, \lambda_G, \lambda_X \in \mathbb{R}$ are tunable coupling parameters.

Then the *Unified Global Coupled Parasymmetric Operator* is defined as:

$$\boxed{U_G^{(\odot)} := \exp\left(i\hat{F}^{(\odot)}_{\text{para}}\right).} \tag{2.56}$$

Interpretation. This operator generates the most general parasymmetric unitary evolution permitted within the framework, simultaneously realizing:

- Local synthesis/dissonance per PQS,
- Pairwise entangled coherence via projectors,
- Multipartite modal-class transitions,
- Dynamical excitation exchange between sites.

It merges modal-logic transformations with physical mode interaction to encode the full dialectical dynamics of parasymmetry.

Definition 2.86 (One Trotter step for $U_G^{(\odot)} = \exp\left(i\hat{F}^{(\odot)}_{\text{para}}\right)$)**.** For generally non-commuting terms, use a r-step first-order Trotterization:

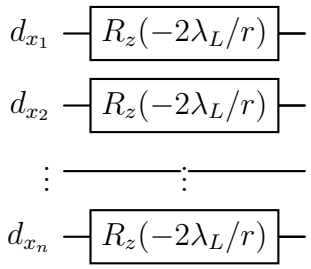
$$U_G^{(\odot)} \approx \left[e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}}\, e^{i\frac{\lambda_P}{r}\hat{F}^{(\text{pair})}_{\text{para}}}\, e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\text{para}}}\, e^{i\frac{\lambda_X}{r}\sum_{i,j}J_{ij}\left(\hat{\sigma}_i^{(+)}\hat{\sigma}_j^{(-)}+\hat{\sigma}_j^{(+)}\hat{\sigma}_i^{(-)}\right)}\right]^r,$$

or the symmetric second-order palindromic variant. One step decomposes into the four segments below.

Definition 2.87 (Local segment $e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}}$)**.** With $\hat{F}^{(\text{local})}_{\text{para}} = \sum_i \tau_z^{(x_i)}$ and $\tau_z^{(x_i)} \equiv Z_{d_{x_i}}$ on $\mathcal{H}^{(x_i)}_{(0,1)}$,

$$e^{i\frac{\lambda_L}{r}\hat{F}^{(\text{local})}_{\text{para}}} = \prod_i e^{i\frac{\lambda_L}{r}Z_{d_{x_i}}} = \prod_i R_z\Big(-2\tfrac{\lambda_L}{r}\Big)_{d_{x_i}}.$$

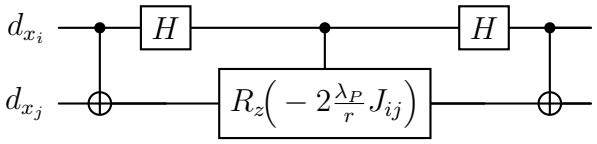
All duality qubits rotate in parallel:



Definition 2.88 (Pairwise segment $e^{i\frac{\lambda_P}{r}\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}}$)**.** Using $P^{(x_ix_j)}_{\mathrm{para}} - P^{(x_ix_j)}_{\mathrm{antipara}} = \frac{1}{2}(X_iX_j + Y_iY_j)$ on duality qubits (d_{x_i}, d_{x_j}), each coupled pair (i,j) evolves by

$$U^{(P)}_{ij} \;:=\; \exp\!\Big(i\,\tfrac{\lambda_P}{r}\,\tfrac{J_{ij}}{2}(X_iX_j + Y_iY_j)\Big).$$

Decompose via inverse-Bell uncompute ($\mathrm{CNOT}(i\to j)$; H_i), controlled R_z, and recompute:



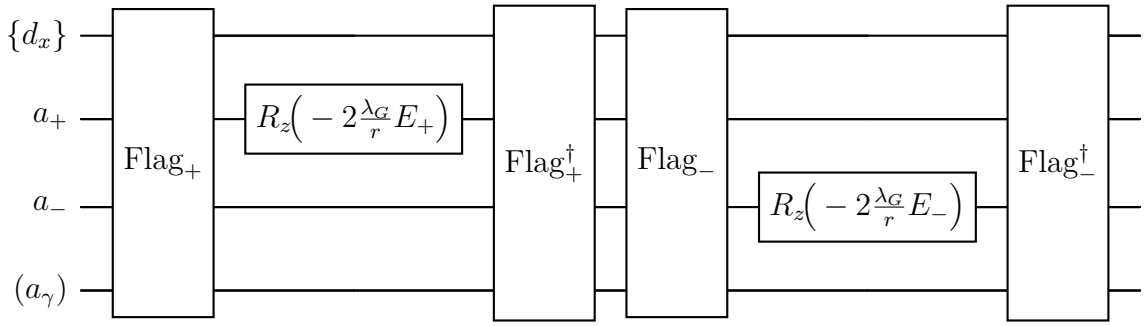
Schedule disjoint pairs in parallel (edge-coloring of the interaction graph).

Definition 2.89 (Global segment $e^{i\frac{\lambda_G}{r}\hat{F}^{(n)}_{\mathrm{para}}}$)**.** Let V_+ and V_- be the n-qubit state-preparation unitaries for $|\Psi^{(n)}_{\mathrm{para}}\rangle$ and $|\widetilde{\Psi}^{(n)}_{\mathrm{antipara}}\rangle$. Define coherent flags with ancillae a_+, a_-:

$$\mathrm{Flag}_+ := V_+\Big(\mathrm{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{n}\mathrm{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_+}\,V_+^\dagger,$$

$$\mathrm{Flag}_- := V_-\Big(\mathrm{CTRL}_{d_{x_1}=1}\prod_{\ell=2}^{n}\mathrm{CTRL}_{d_{x_\ell}=0}\Big)\,X_{a_-}\,V_-^\dagger.$$

Phase-kickback realizes eigenphases of $\hat{F}^{(n)}_{\mathrm{para}} = E_+P^{(x_1\ldots x_n)}_{\mathrm{para}} + E_-P^{\overbrace{(x_1\ldots x_n)}}_{\mathrm{antipara}} + \sum_\gamma E_\gamma P_\gamma$:

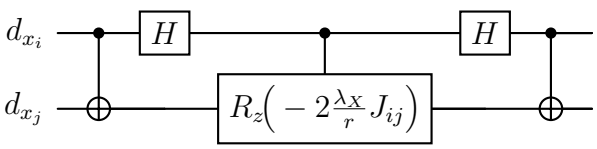


(Extend with additional flags for any P_γ terms if needed.)

Definition 2.90 (Exchange segment $e^{i\frac{\lambda_X}{r}\sum_{i,j}J_{ij}(\hat{\sigma}^{(+)}_i\hat{\sigma}^{(-)}_j+\hat{\sigma}^{(+)}_j\hat{\sigma}^{(-)}_i)}$)**.** Since $\hat{\sigma}^{(\pm)} = \frac{1}{2}(X \pm iY)$, each pair contributes the same XY–exchange primitive as in Definition 2.88:

$$U^{(X)}_{ij} \;:=\; \exp\!\Big(i\,\tfrac{\lambda_X}{r}\,\tfrac{J_{ij}}{2}(X_iX_j + Y_iY_j)\Big),$$

with the identical two–CNOT + R_z decomposition:



Remark 2.91 (Merging identical XY contributions)**.** Because both Definition 2.88 and Definition 2.90 implement $\exp\Big(i\,\frac{\alpha_{ij}}{2}(X_iX_j + Y_iY_j)\Big)$ on each pair, they can be *combined* per Trotter slice by using a single block with effective angle

$$\alpha_{ij}^{\text{eff}} \;=\; \tfrac{1}{r}\,(\lambda_P + \lambda_X)\,J_{ij},$$

thereby halving the two–CNOT overhead per pair.

Definition 2.92 (One unified step and repetition)**.** A single step is the concatenation

$$\boxed{\mathcal{S}_\odot \;:=\; e^{\,i\frac{\lambda_L}{r}\hat{F}_{\text{para}}^{(\text{local})}}\Big[\prod_{(i,j)\in E} U_{ij}^{(P)}\Big]\,e^{\,i\frac{\lambda_G}{r}\hat{F}_{\text{para}}^{(n)}}\Big[\prod_{(i,j)\in E} U_{ij}^{(X)}\Big]} \quad\Rightarrow\quad U_G^{(\odot)} \;\approx\; \big(\mathcal{S}_\odot\big)^r,$$

where E is the edge set of the coupling graph induced by $\{J_{ij}\}$. Parallelize the pair/exchange layers over disjoint matchings; the two global flags commute (orthogonal projectors).

Remark 2.93 (Resource sketch)**.** Per Trotter step: n parallel single-qubit R_z (local); per coupled pair, two CNOTs + one R_z (XY) — or one such block with angle α_{ij}^{eff} if merged; and two n-controlled flags plus two ancilla R_z for the global modal-class segment (extend for P_γ as needed). Depth per step scales with the edge-coloring number of E and the decomposition depth of the multi-controlled Toffoli used in the flags.

2.2.16 Definition: Parasymmetry (Synthesis)

Definition 2.94 (Parasymmetry (Synthesis): Compact Formal Definition)**.** Fix the distinguished $(0,1)$ modal sector at a PQS $\mathfrak{B}_x$ with basis $\{|e_1\rangle_x, |e_2\rangle_x\}$ corresponding to Symmetry/Antisymmetry (cf. Definition 1.16 and Section 2.1). Define the normalized parasymmetric/anti-parasymmetric kets

$$|+\rangle_x := \tfrac{1}{\sqrt{2}}\Big(|e_1\rangle_x + |e_2\rangle_x\Big), \qquad |-\rangle_x := \tfrac{1}{\sqrt{2}}\Big(|e_1\rangle_x - |e_2\rangle_x\Big),$$

and the local effects

$$P_{\text{para}}^{(x)} := |+\rangle_x\langle+|, \qquad P_{\text{antipara}}^{(x)} := |-\rangle_x\langle-|, \tag{2.57}$$

which are orthogonal projectors with $P_{\text{para}}^{(x)} + P_{\text{antipara}}^{(x)} = P_{(0,1)}^{(x)}$ (the $(0,1)$-sector projector). The Born-valued synthesis truth in state ρ is $v_{\text{Synthesis}}(\rho) = \text{Tr}\Big(P_{\text{para}}^{(x)}\rho\Big)$ (Definition 1.18). Measuring the complementary observable (Σ_x on the logical qubit) operationalizes this test.

(P1) Multipartite parasymmetric coherence. For PQS sites $x_1, \ldots, x_n$, define bipartite and global effects that witness *distributed synthesis*:

$$\text{(pair)}\quad |\Psi_{\text{para}}^{(ij)}\rangle := \tfrac{1}{\sqrt{2}}\Big(|e_1\rangle_{x_i}|e_2\rangle_{x_j} + |e_2\rangle_{x_i}|e_1\rangle_{x_j}\Big), \quad P_{\text{para}}^{(x_ix_j)} := |\Psi_{\text{para}}^{(ij)}\rangle\langle\Psi_{\text{para}}^{(ij)}|, \tag{2.58}$$

$$\text{(global)}\quad |\Psi_{\text{para}}^{(n)}\rangle := \tfrac{1}{\sqrt{n}}\sum_{k=1}^{n} |e_1\rangle_{x_1}\cdots|e_2\rangle_{x_k}\cdots|e_1\rangle_{x_n}, \qquad P_{\text{para}}^{(x_1\ldots x_n)} := |\Psi_{\text{para}}^{(n)}\rangle\langle\Psi_{\text{para}}^{(n)}|. \tag{2.59}$$

These states (i) are permutation-symmetric, (ii) exhibit genuine multipartite entanglement with mixed single-site marginals, and (iii) reduce locally to the $(0,1)$ sector. They realize Synthesis as *relation*: no single site carries the whole pattern (cf. Section 2.2.3 and eq. (2.29)).

(P2) Parasymmetry-preserving dynamics. A unitary U on the n-site $(0,1)$ sector $\mathcal{H}_{(0,1)}^{\otimes n}$ is *parasymmetry-preserving* if and only if it leaves the parasymmetric subspace invariant:

$$U\, P_{\text{para}}^{(x_1\ldots x_n)}\, U^\dagger = P_{\text{para}}^{(x_1\ldots x_n)}. \tag{2.60}$$

Equivalently, U maps the span of the states in (2.58)–(2.59) to itself. This class includes:

(i) Decoupled evolutions.
Decoupled evolutions $U = \bigotimes_i U_i$ with each U_i a rotation about the parasymmetric axis (preserving $\{|+\rangle_x, |-\rangle_x\}$).

(ii) Coupled evolutions.
Coupled evolutions generated by exchange-type Hamiltonians (e.g. $XX{+}YY$ on the logical qubits) that conserve the single-excitation manifold and stabilize $|\Psi_{\text{para}}^{(n)}\rangle$.

(iii) Global parasymmetric drives.
Global parasymmetric drives $U_{\text{para}} = \exp\!\left(i\hat{F}_{\text{para}}\right)$ with Hermitian $\hat{F}_{\text{para}}$ satisfying

$$[\hat{F}_{\text{para}}, P_{\text{para}}^{(x_1\ldots x_n)}] = 0$$

(cf. Definition 2.85).

(P3) Equivalences and closure. Parasymmetric realizations related by (i) local rephasings $|e_1\rangle \mapsto e^{i\phi}|e_1\rangle$, $|e_2\rangle \mapsto e^{-i\phi}|e_2\rangle$; (ii) relabeling of sites; or (iii) common conjugation within the $(0,1)$ sector are *operationally equivalent*: they yield the same family of effects and Born valuations. The pair $\{P_{\text{para}}^{(x)}, P_{\text{antipara}}^{(x)}\}$ is a complete, orthogonal resolution of $P_{(0,1)}^{(x)}$, ensuring basis-coherence with Thesis/Antithesis.

Interpretation. Parasymmetry names *coherent organization* rather than compromise: locally it is the $|+\rangle$ filter; globally it is distributed alignment that no single site owns. Its truth is the measurable propensity $v_{\text{Synthesis}}(\rho)$ (Definition 1.18), and its dynamics are those that conserve the parasymmetric pattern while allowing it to propagate and entangle across PQSs.

Intuitive reading. Parasymmetry is not a compromise between Symmetry and Antisymmetry; it is a *pattern of coherent organization*. Locally, the $|+\rangle$ filter in (2.57) asks: "Does the system register in the *coherent* direction that aligns the two poles?" Its Born truth $v_{\text{Synthesis}}(\rho) = \text{Tr}(P_{\text{para}}^{(x)}\rho)$ (Definition 1.18) is therefore a measure of *coherence*, not mere population. Two preparations can have the same P_T/P_A weights yet differ sharply in $v_{\text{Synthesis}}$—a classical mixture keeps masses on the poles, a coherent superposition points along the parasymmetric axis. Read this way, Synthesis is the corner of the Fourfold Dialectic Algebra (Definition 1.16) that detects "*togetherness with phase*," i.e., aligned disposition under the complementary test.

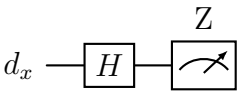
Operational picture. To probe Parasymmetry at one site, rotate and measure the logical qubit along the parasymmetric axis (the Σ_x basis). Projecting with $P_{\text{para}}^{(x)}$ implements a repeatable *test & filter*: repeated trials estimate $v_{\text{Synthesis}}(\rho)$, while post-selection prepares the $|+\rangle$ mode for downstream dynamics. In the many-site setting, the bipartite projector (2.58) and the global projector (2.59) turn Synthesis into a *relation*: the signature is no longer at any single PQS, but in their joint registration. The pair state is Bell-like (one excitation shared), while

the global state is W-like (single-excitation delocalization) with permutation symmetry and mixed one-site marginals; both realize "distributed co-alignment."

Dynamics and robustness. Equation (2.60) characterizes the evolutions that preserve Synthesis: a unitary U is parasymmetry-preserving iff it leaves $P_{\text{para}}^{(x_1\cdots x_n)}$ invariant. Practically, this includes (i) local rotations that keep the $\{|+\rangle, |-\rangle\}$ axis fixed; (ii) exchange-type couplings (e.g. $XX{+}YY$ on the logical qubits) that stabilize the single-excitation manifold and propagate coherence; and (iii) global drives generated by $\hat{F}_{\text{para}}$ with $[\hat{F}_{\text{para}}, P_{\text{para}}^{(x_1\cdots x_n)}] = 0$. Couplings that leak weight outside the $(0,1)$ sector or that dephase the $\{|e_1\rangle, |e_2\rangle\}$ coherence reduce $v_{\text{Synthesis}}$—they do not "negate" Synthesis so much as *dilute* the very resource it measures. Because the global W-like pattern is spread across sites, it is notably robust to loss of a single constituent (the signature property of W-type coherence), making it a natural carrier of parasymmetric order.

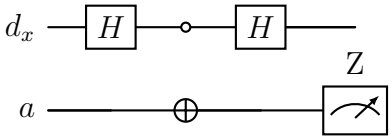
What Synthesis is (and is not). Synthesis tolerates nonzero Thesis *and* Antithesis valuations: bivalence is recovered only when one pole saturates. But high $v_{\text{Synthesis}}$ demands *phase-coherent* co-alignment, not a probabilistic blend. Thus Parasymmetry is the quantitative hinge between the "both/neither" possibilities of the dialectic and an experimentally legible notion of togetherness: a disposition to register along the coherent axis locally, and to share a single organized pattern nonlocally.

Definition 2.95 (Local parasymmetric effect $P_{\text{para}}^{(x)} = |+\rangle\langle+|$ as a circuit)**.** Since $P_{\text{para}}^{(x)} = \frac{1}{2}(\mathbb{I}+X)$, measuring X operationalizes (2.57). Equivalently, Hadamard then Z-measurement:



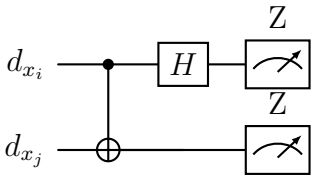
$$\Pr[0] = \mathrm{Tr}\Big(P_{\text{para}}^{(x)}\rho\Big), \quad \Pr[1] = \mathrm{Tr}\Big(P_{\text{antipara}}^{(x)}\rho\Big).$$

(Coherent/Naimark flag for $|+\rangle$: apply H, then a zero–control to flip an ancilla, then H back.)



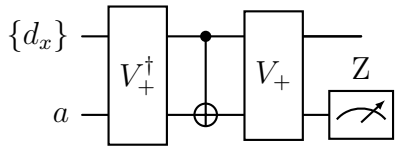
Outcome a=1 implements projection onto $|+\rangle$.

Definition 2.96 (Pair parasymmetric projector $P_{\text{para}}^{(x_i x_j)} = |\Psi_{\text{para}}^{(ij)}\rangle\langle\Psi_{\text{para}}^{(ij)}|$)**.** Here $|\Psi_{\text{para}}^{(ij)}\rangle = \frac{1}{\sqrt{2}}(|01\rangle + |10\rangle) = |\Psi^+\rangle$ (on d_{x_i}, d_{x_j}). Inverse Bell transform (CNOT then H on the first qubit) maps $\{|\Phi^+\rangle, |\Phi^-\rangle, |\Psi^+\rangle, |\Psi^-\rangle\} \to \{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$. Postselect $(1,0)$ to realize $P_{\text{para}}^{(x_i x_j)}$:



Coherent flag (no collapse): replace meters by a zero/one–conditioned multi-control on an ancilla and uncompute.

Definition 2.97 (Global parasymmetric projector $P_{\text{para}}^{(x_1\cdots x_n)} = |\Psi_{\text{para}}^{(n)}\rangle\langle\Psi_{\text{para}}^{(n)}|$)**.** Let V_+ be the n-qubit state-prep circuit that maps a seed $|10\cdots0\rangle$ to the W-type state $|\Psi_{\text{para}}^{(n)}\rangle$ of (2.59). A Naimark flag for $|\Psi_{\text{para}}^{(n)}\rangle$:



The control is conditioned on the computational pattern $10\cdots0$ after $V_+^\dagger$; outcome a=1 realizes $P_{\text{para}}^{(x_1\cdots x_n)}$.

Definition 2.98 (Circuits for parasymmetry-preserving unitaries (implement (2.60)))**.** A unitary U preserves parasymmetry iff $[U, P_{\text{para}}^{(x_1\cdots x_n)}] = 0$. Representative circuit classes:

1. **Decoupled local rotations about the parasymmetric axis.** Since $P_{\text{para}}^{(x)} = \frac{1}{2}(\mathbb{I} + X)$, any $U_x = e^{i\theta_x X}$ commutes with $P_{\text{para}}^{(x)}$:

   and $U = \bigotimes_x U_x$ preserves (2.60).

2. **Pairwise XY exchange (stabilizes the single-excitation manifold).** Using $P_{\text{para}}^{(x_ix_j)} - P_{\text{antipara}}^{(x_ix_j)} = \frac{1}{2}(X_iX_j + Y_iY_j)$,

$$U_{ij}(\alpha) = \exp\Big(i\tfrac{\alpha}{2}(X_iX_j + Y_iY_j)\Big) \quad \equiv$$

   These gates conserve excitation number and hence preserve the W-sector spanned by (2.59).

3. **Global modal-class phase drives.** If $\hat{F}_{\text{para}}^{(n)} = E_+P_{\text{para}}^{(x_1\cdots x_n)} + E_-\widetilde{P_{\text{antipara}}^{(x_1\cdots x_n)}} + \cdots$, then $U_{\text{para}} = \exp\big(i\hat{F}_{\text{para}}^{(n)}\big)$ is implemented by flagged phase kickback on the two rank-1 subspaces:

   with phases $\phi_\pm$ set by the desired eigenphases on $|\Psi_{\text{para}}^{(n)}\rangle$ and its orthogonal complement.

Remark 2.99 (Operational equivalences and closure)**.** Local rephasings and site permutations correspond to Z-rotations and wire-swaps; common conjugations within the $(0,1)$ sector are implemented by uniform single-qubit basis changes (e.g. global H or R_z layers). These redundancies leave all circuits above invariant in their Born statistics, matching Definition 2.94.

Local characterization. Parasymmetry on the distinguished $(0,1)$ modal sector is the coherent superposition structure singled out by the projectors $P^{(x)}_{\text{para}}$ and $P^{(x)}_{\text{antipara}}$ in Definition 2.94. With $|+\rangle_x = \frac{1}{\sqrt{2}}(|e_1\rangle_x + |e_2\rangle_x)$ and $|-\rangle_x = \frac{1}{\sqrt{2}}(|e_1\rangle_x - |e_2\rangle_x)$, the effects $P^{(x)}_{\text{para}} = |+\rangle_x\langle+|$, $P^{(x)}_{\text{antipara}} = |-\rangle_x\langle-|$ (eq. (2.57)) resolve the $(0,1)$-sector as a pair of orthogonal X-eigenspaces. Operationally, measuring the complementary observable Σ_x on the logical qubit implements the synthesis test, i.e. the Born valuation $v_{\text{Synthesis}}(\rho) = \text{Tr}(P^{(x)}_{\text{para}}\rho)$ in Definition 2.94.

Distributed (pair and global) synthesis. Parasymmetry elevates local synthesis to relational coherence across sites via the pair state $|\Psi^{(ij)}_{\text{para}}\rangle = \frac{1}{\sqrt{2}}(|e_1\rangle_{x_i}|e_2\rangle_{x_j} + |e_2\rangle_{x_i}|e_1\rangle_{x_j})$ and its projector $P^{(x_ix_j)}_{\text{para}}$ (eq. (2.58)), as well as the multipartite W-type state $|\Psi^{(n)}_{\text{para}}\rangle$ and projector $P^{(x_1\ldots x_n)}_{\text{para}}$ (eq. (2.59)). These effects witness *distributed synthesis*: the pattern is encoded nonlocally, with permutation symmetry, mixed single-site marginals, and support confined to the $(0,1)$ sector (cf. eq. (2.29)).

Circuit interpretation. At the circuit level, the local effect $P^{(x)}_{\text{para}}$ is realized by an X-eigenstate test (e.g. Hadamard followed by a Z-measurement), which directly computes $\text{Tr}(P^{(x)}_{\text{para}}\rho)$ as in Definition 2.94 and eq. (2.57). The pair effect $P^{(x_ix_j)}_{\text{para}}$ is implemented by mapping the Bell basis to the computational basis and testing for the symmetric exchange component specified in eq. (2.58). The global effect $P^{(x_1\ldots x_n)}_{\text{para}}$ is implemented by coherently flagging the W-state of eq. (2.59) via state-preparation unitaries and Naimark dilation, thereby projecting onto the subspace of multipartite synthesis.

Parasymmetry-preserving dynamics. A unitary U preserves parasymmetry precisely when it stabilizes the parasymmetric subspace, $UP^{(x_1\ldots x_n)}_{\text{para}}U^\dagger = P^{(x_1\ldots x_n)}_{\text{para}}$ (eq. (2.60)). This includes (i) decoupled local rotations about the parasymmetric axis (single-qubit X-axis rotations that commute with eq. (2.57)); (ii) coupled XY-type exchanges $\exp\left(i\frac{\alpha}{2}(X_iX_j + Y_iY_j)\right)$ that conserve excitation number and thus preserve the W-manifold underlying eq. (2.59); and (iii) global modal-class drives $U_{\text{para}} = \exp\left(i\hat{F}^{(n)}_{\text{para}}\right)$ whose generators commute with $P^{(x_1\ldots x_n)}_{\text{para}}$, as encompassed by the unified constructions in Definition 2.85.

Synthesis as an operational principle. In summary, parasymmetry designates the X-eigenstructure of each duality qubit and its coherent uplift to nonlocal, permutation-symmetric entanglement. Its circuits project onto, preserve, phase, and transport the synthesis content specified by Definition 2.94 and eqs. (2.58) and (2.59), while the admissible evolutions are exactly those unitaries satisfying the invariance criterion eq. (2.60).

Intuitive essence. Parasymmetry designates the balanced coherence within the distinguished $(0,1)$ sector: locally it is the equal-weight superposition $|+\rangle_x = \frac{1}{\sqrt{2}}(|e_1\rangle_x + |e_2\rangle_x)$ singled out by the effect $P^{(x)}_{\text{para}} = |+\rangle_x\langle+|$ (Definition 2.94 and eq. (2.57)). Rather than committing to either mode (Symmetry/Antisymmetry), the parasymmetric effect identifies the "midpoint" state that coherently synthesizes both. The complementary effect $P^{(x)}_{\text{antipara}}$ identifies the orthogonal dissonant alternative.

Distributed synthesis. Beyond a single site, parasymmetry becomes a relational property encoded in correlations. In the bipartite case, synthesis is witnessed by the symmetric exchange state $|\Psi^{(ij)}_{\text{para}}\rangle = \frac{1}{\sqrt{2}}(|e_1\rangle_{x_i}|e_2\rangle_{x_j} + |e_2\rangle_{x_i}|e_1\rangle_{x_j})$ and its projector $P^{(x_i x_j)}_{\text{para}}$ (eq. (2.58)). Globally, the parasymmetric W-state $|\Psi^{(n)}_{\text{para}}\rangle$ delocalizes a single antisymmetry excitation over all sites, defining the projector $P^{(x_1\ldots x_n)}_{\text{para}}$ (eq. (2.59)). In both cases, synthesis is realized as a nonlocal pattern: no single site carries the entire structure.

Operational role. Operationally, parasymmetry *selects* coherent synthesis and *maintains* it under admissible dynamics. Selection is achieved by testing the local effect $P^{(x)}_{\text{para}}$ and its pair/global analogues (eqs. (2.57) to (2.59)), yielding the Born valuation $v_{\text{Synthesis}}(\rho) = \text{Tr}(P^{(x)}_{\text{para}}\rho)$ (Definition 2.94). Maintenance is characterized by the invariance criterion $U\,P^{(x_1\ldots x_n)}_{\text{para}}U^\dagger = P^{(x_1\ldots x_n)}_{\text{para}}$ (eq. (2.60)), which is satisfied by (i) local rotations about the parasymmetric axis, (ii) number-conserving XY exchange unitaries on pairs that stabilize the single-excitation manifold, and (iii) global modal-class drives generated by Hermitians commuting with $P^{(x_1\ldots x_n)}_{\text{para}}$ (cf. Definition 2.85).

Conceptual summary. Parasymmetry is the coherent "both-at-once" structure of the duality qubit lifted to a collective, permutation-symmetric relation across many sites. Its formal content is the family of effects and states in Definition 2.94 and eqs. (2.58) and (2.59), together with the closed class of evolutions that preserve these effects (eq. (2.60)). In this sense, parasymmetry performs two tasks: it filters for synthesis and it enables synthesis to propagate, interfere, and organize globally without fracturing the coherent pattern that defines it.

2.3 Holosymmetry: The Quantum Realization of Holothesis

Holosymmetry represents one of the most profound manifestations of quantum mechanics within this treatise: the coherent superposition of entire evolutionary histories of worlds. Unlike conventional quantum superposition, which operates on states within a fixed dynamical framework, Holosymmetry enables the simultaneous exploration of fundamentally different evolutionary pathways—a quantum mechanical realization of parallel universes at the most elementary level of reality.

At its heart, Holosymmetry orchestrates a cosmic dance between two emergent quantum registers, each comprising n Primordial Quantum Singularities (Definition 1.25). These registers—designated Register A and Register B—are collections of quantum entities as well as independent instantiations of the universe's fundamental duality structure. Each

PQS within these registers, expressed as $\mathfrak{B}_x \equiv \hat{\mathbf{\Omega}}_x = \overset{\circ}{\mathbf{\Lambda}}_{x,\hat{\Theta}_x}$, embodies the irreducible quantum-relational architecture from which spacetime itself emerges.

The revolutionary aspect of Holosymmetry lies in its ability to place these entire registers into quantum superposition with respect to their dynamical evolution. Through the mediation of a control quantum system—itself an PQS residing in the modal Hilbert space $\mathcal{H}_c$ (eq. (2.64))—the framework enables each register to simultaneously experience both coupled and non-coupled parasymmetric evolution (Definition 2.85). This is a fundamental feature of how the pre-geometric substrate explores the landscape of possible emergent geometries, thus freeing it from a mere theoretical curiosity.

The control system acts as a quantum switch, entangling itself with the evolutionary fate of both registers. When in state $|\mathbf{0}\rangle_c$, it guides Register A through coupled parasymmetric dynamics while Register B evolves under non-coupled dynamics. In state $|\mathbf{1}\rangle_c$, these roles reverse. But through quantum superposition, the control system can exist in both states simultaneously, creating an entangled configuration where both evolutionary histories coexist—a superposition of spacetime's possible emergent structures.

This construction elevates the Quantum Holo-State $|\overset{\circ}{\mathbf{\Psi}}\rangle$ (Definition 1.27) from a static encoding of quantum correlations to a dynamic generator of parallel realities. Each evolutionary path carves out a different trajectory through the space of possible geometric configurations, and Holosymmetry ensures that quantum interference between these paths becomes physically meaningful. The result is a framework where the very notion of a unique evolutionary history dissolves into a quantum superposition of possibilities, each weighted by complex amplitudes that encode the deep relational structure of the PQS network.

In essence, Holosymmetry transforms the question "Which dynamical evolution did the system undergo?" into the quantum mechanical statement "The system underwent all compatible evolutions simultaneously, with quantum interference determining the observable outcome.". This represents the ultimate expression of quantum mechanics' radical departure from classical determinism, now applied to the very fabric of emergent spacetime itself.

2.3.1 System Definition and Component Operators

Why two registers (and a control) for Holosymmetry. Holosymmetry tests a meta-level question: it compares *entire evolutionary histories*, not just states. To do this without ambiguity or higher-order wiring, we require two disjoint n-PQS registers so that mutually exclusive global regimes can be instantiated *in parallel* and then coherently contrasted. In our setting the alternative parasymmetric evolutions are $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, where one register runs the globally coupled dynamics (G) while the other runs the decoupled/normal dynamics (N) and vice versa (cf. Definition 2.85). A single control qubit then prepares, addresses, and recombines these two global histories, realizing the holosymmetric unitary in the normal form of eq. (3.35) and Section 3.8, (3.35). In this architecture the measured quantity is a *propensity*, the Born valuation of the holosymmetric effect $E_{\mathrm{Holo}}^{(\mathbf{a}\nrightarrow\mathbf{b})}$ defined in (3.36) and evaluated via Definition 1.18.

Minimal, symmetry-respecting, and operationally complete. The dual-register scaffold is minimal: it is the least structure that lets us form sums/differences of histories and

expose their relational content under different control bases. It also realizes the Principle of Duality and an $A \leftrightarrow B$ swap symmetry by construction: exchanging registers or applying common conjugations leaves the family of effects—and hence the valuations—unchanged (Holosymmetry equivalences (H4) in Section 3.8). Crucially, the same backbone unifies the three operational presentations (interferometer, path-scattering, and commutator-lensing): choices of $\mathbf{U}_{\text{prep}}$ and $\mathbf{U}_{\text{read}}$ together with the $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$ or $\{|+\rangle_c, |-\rangle_c\}$ control bases recover each model (see Definitions 2.114 and 2.119 and Notes (i) in Section 3.8). All of this remains within fixed causal order—Holosymmetry superposes *which global unitary runs where*, not the *order* of gates—so the construction stays fully unitary and experimentally standard.

Definition 2.100 (Axiom (Principle) of Duality)**.** For every ontological assertion admissible in the Fourfold Dialectic Algebra (Definition 1.16) there exists a distinguished, complementary counter-assertion such that:

(i) **Ontological layer.** Each PQS $\mathfrak{B}_x$ carries a privileged dual pair (Symmetry/Antisymmetry), generating the $(0, 1)$ sector and its complementary (parasymmetric) axis.

(ii) **Algebraic layer.** The pair is realized by effects P_T, P_A with $P_T + P_A = P_{(0,1)}$ and complementary effects $P_{\text{para}}, P_{\text{antipara}}$; truth is Born-valued $v(\rho; P) = \text{Tr}(P\rho)$ (Definition 1.18).

(iii) **Operational layer.** Physical constructions respect the duality symmetry: swapping the dual branches (or relabeling them globally) leaves all induced valuations invariant, up to unitary equivalence on the tested space.

Duality as the design principle for Holosymmetry. Holosymmetry compares *alternative histories*, so the Axiom of Duality (Section 1.2.6 and Definition 2.100) must be realized not only for *states* but for *processes*. The minimal, symmetry-respecting way is to instantiate two disjoint n-PQS registers so that the mutually exclusive global regimes can be run *in parallel* and then coherently contrasted. Concretely, the dual pair of path unitaries $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ assigns "global–coupled" (G) to one register while the other runs "normal/decoupled" (N), and vice versa; a single control prepares, addresses, and recombines these histories to realize the normal form in eq. (3.35) and Section 3.8, (3.35). The measured quantity is a Born propensity, $v_{\text{Holothesis}}(\rho_{\text{RR}}) = \text{Tr}\Big(E_{\text{Holo}}^{(\mathbf{a}\nrightarrow\mathbf{b})}\, \rho_{\text{RR}}\Big)$ from (3.36), which reports "synthesis vs. dissonance'' of the two histories under the chosen preparation/readout. With this duality-driven motivation in place, we now specify the two registers and the composite holosymmetric Hilbert space.

Definition 2.101 (Dual Primordial Registers and Holosymmetric Hilbert Space)**.** Let $\mathcal{X}_q$ denote the emergent quantum configuration space of Primordial Quantum Singularities (PQSs), as defined in Proposition 4.625. For a holosymmetric system, define two disjoint, factorized quantum registers:

- **Register A**: $\mathcal{X}_q^{(A)} = \{x_1^{(A)}, \ldots, x_n^{(A)}\} \subset \mathcal{X}_q$,
- **Register B**: $\mathcal{X}_q^{(B)} = \{x_1^{(B)}, \ldots, x_n^{(B)}\} \subset \mathcal{X}_q$,

with $\mathcal{X}_q^{(A)} \cap \mathcal{X}_q^{(B)} = \emptyset$, such that each register contains n distinct PQSs.

Modal Structure Each PQS $\mathfrak{B}_x \in \mathcal{X}_q$ possesses a local modal Hilbert space:

$$\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} := \mathbb{C}^4,$$

corresponding to the full fourfold dialectical spectrum: Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry.

The Hilbert space of a single register $\mathcal{X}_q^{(A)}$ or $\mathcal{X}_q^{(B)}$ is then:

$$\mathcal{H}_{\text{PQS}}^{(n,A)} := \bigotimes_{i=1}^{n} \mathcal{H}_{\text{mod}}^{(x_i^{(A)})} \cong (\mathbb{C}^4)^{\otimes n}, \quad \mathcal{H}_{\text{PQS}}^{(n,B)} := \bigotimes_{i=1}^{n} \mathcal{H}_{\text{mod}}^{(x_i^{(B)})} \cong (\mathbb{C}^4)^{\otimes n}.$$

Dual Register Hilbert Space We define the combined Hilbert space of the two independent PQS registers—each containing n sites—as the *dual register Hilbert space*, denoted:

$$\boxed{\mathcal{H}_{\text{RR}}^{(2n)} := \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)} \cong (\mathbb{C}^4)^{\otimes 2n}.} \tag{2.61}$$

Here:

- $\mathcal{H}_{\text{PQS}}^{(n,A)} := \bigotimes_{i=1}^{n} \mathcal{H}_{\text{mod}}^{(x_i^{(A)})}$ and
- $\mathcal{H}_{\text{PQS}}^{(n,B)} := \bigotimes_{i=1}^{n} \mathcal{H}_{\text{mod}}^{(x_i^{(B)})}$,

with $\mathcal{H}_{\text{mod}}^{(x)} = \mathbb{C}^4$ the full four-dimensional modal Hilbert space at each PQS.

The label **RR** stands for *Primordial Registers*, emphasizing the factorized structure of the total configuration across the two modal subsystems. This construction forms the tensorial base upon which holosymmetric operators act, either jointly or in superposition.

Control System and Holosymmetric Sector Introduce an auxiliary control qubit space $\mathcal{H}_c \cong \mathbb{C}^2$, enabling controlled superpositions of dynamical histories.

Then the full holosymmetric Hilbert space is:

$$\boxed{\mathcal{H}_{\text{Holo}} := \mathcal{H}_c \otimes \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}.} \tag{2.62}$$

Dimensionality. We work on the factorized space

$$\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_R^{(n)} \otimes \mathcal{H}_{R'}^{(n)} \cong \mathbb{C}^2 \otimes \mathbb{C}^{4^n} \otimes \mathbb{C}^{4^n}.$$

$$\boxed{\dim(\mathcal{H}_{\text{Holo}}) = \dim(\mathcal{H}_c)\, \dim(\mathcal{H}_R^{(n)})\, \dim(\mathcal{H}_{R'}^{(n)}) = 2 \cdot 4^n \cdot 4^n = 2 \times 4^{2n} = 2^{4n+1}.} \tag{2.63}$$

Interpretation. This dual-register structure forms the holosymmetric substrate for constructing entangled path histories, interference geometry, and higher-order duality transformations across PQS configurations. It generalizes parasymmetry from single-register dynamics to controlled entangled evolution over bipartite modal landscapes.

This exponential scaling reflects the full modal richness of holosymmetric evolution. With $2n$ Primordial Quantum Singularities distributed across two registers, each possessing four distinct dialectical modes, plus one control qubit, the system can explore 2^{4n+1} orthogonal quantum states—enabling deep superpositions of entangled causal geometries within the emergent spacetime fabric.

Definition 2.102 (Control System for Holosymmetric Evolution)**.** The holosymmetric framework incorporates a quantum control mechanism that coherently selects between distinct dynamical regimes applied to two disjoint PQS registers. This control system is implemented by a two-level quantum system (qubit) with Hilbert space:

$$\boxed{\mathcal{H}_c := \text{span}\left\{|\mathbf{0}\rangle_c,\ |\mathbf{1}\rangle_c\right\},} \tag{2.64}$$

where the orthonormal basis states represent complementary dynamical assignments:

$$\boxed{\begin{aligned} |\mathbf{0}\rangle_c &\equiv \begin{cases} \text{Register A: } U_G^{(\odot)} \text{ (unified global coupled evolution)}, \\ \text{Register B: } U_N^{(\odot)} \text{ (generalized composite decoupled evolution)}, \end{cases} \\ |\mathbf{1}\rangle_c &\equiv \begin{cases} \text{Register A: } U_N^{(\odot)} \text{ (generalized composite decoupled evolution)}, \\ \text{Register B: } U_G^{(\odot)} \text{ (unified global coupled evolution)}. \end{cases} \end{aligned}} \tag{2.65}$$

When the control state is prepared in a coherent superposition:

$$|\phi_c\rangle = \alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c, \qquad \alpha, \beta \in \mathbb{C}, \quad |\alpha|^2 + |\beta|^2 = 1,$$

the resulting system undergoes a quantum superposition of full modal evolutions, where the assignment of coupling modes to the registers is no longer sharply defined.

This defines the operational heart of *holosymmetry*: a mode of evolution where distinct parasymmetric histories—comprising separable and entangled, local and global coherence structures—interfere through controlled quantum superposition. It encodes a higher-order synthesis across the modal and geometrical structures of Primordial Quantum Singularities.

Lifted Operators on Dual PQS Registers

Definition 2.103 (Lifted Parasymmetric Operators on Dual Primordial Quantum Singularity Registers)**.** Let $\mathcal{H}_{\text{RR}}^{(2n)} := \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}$ denote the dual register Hilbert space of two disjoint PQS configurations (eq. (2.61)).

Let $U_G^{(\odot)}$ and $U_N^{(\odot)}$ be the unified global coupled and generalized decoupled parasymmetric operators, respectively (Definitions 2.66 and 2.85).

We define the **lifted operators** acting on the dual space $\mathcal{H}_{\text{RR}}^{(2n)}$ by extending the action of each operator to one register while leaving the other invariant:

$$U_G^{(A)} := U_G^{(\odot)} \otimes \mathbb{I}^{(B)}, \qquad U_N^{(A)} := U_N^{(\odot)} \otimes \mathbb{I}^{(B)}, \tag{2.66}$$

$$U_G^{(B)} := \mathbb{I}^{(A)} \otimes U_G^{(\odot)}, \qquad U_N^{(B)} := \mathbb{I}^{(A)} \otimes U_N^{(\odot)}, \tag{2.67}$$

where:

- $\mathbb{I}^{(A)}$ and $\mathbb{I}^{(B)}$ are identity operators on $\mathcal{H}_{\text{PQS}}^{(n,A)}$ and $\mathcal{H}_{\text{PQS}}^{(n,B)}$, respectively;
- The superscripts (A) and (B) denote selective action restricted to Register A or Register B.

Interpretation. This lifting formalism enables the application of structurally distinct parasymmetric dynamics to each register, with the following implications:

- $U_G^{(A)}$: Applies a fully entangled, globally coupled parasymmetric evolution within Register A, while Register B remains static.
- $U_N^{(B)}$: Applies a factorizable, decoupled parasymmetric evolution within Register B, leaving Register A unchanged.
- All such lifted operators preserve the tensor product structure of $\mathcal{H}_{\text{RR}}^{(2n)}$, making them compatible with controlled superpositions across registers.

Holosymmetric Role. These lifted operators form the operational backbone of the holosymmetric architecture. They enable coherent dynamical differentiation between registers, making it possible to construct quantum superpositions of mutually exclusive modal histories—where Register A and Register B may evolve under independent coherence constraints, yet remain entangled via the overarching control system.

The Necessity of Lifting: From Mathematical Requirement to Physical Reality The concept of "lifting" operators in the holosymmetric framework reveals a profound mathematical necessity that mirrors the philosophical depth of the Holothesis itself. To understand why lifting is convenient and absolutely essential, we must trace the logical architecture from its foundations through to its revolutionary physical implications.

The Structural Foundation Consider the architecture of the holosymmetric universe: we have constructed a total Hilbert space $\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}$ that is explicitly factorized across three independent subsystems—a control qubit and two quantum registers, each containing n Primordial Quantum Singularities. This tripartite structure embodies the very essence of holosymmetric logic, where different evolutionary histories must coexist in carefully orchestrated quantum superposition.

The heart of holosymmetry lies in its ability to coherently superpose distinct assignments of modal dynamics. In one branch of reality, Register A might evolve under the globally coupled operator $U_G^{(\odot)}$ while Register B evolves under the decoupled operator $U_N^{(\odot)}$. In another branch, these assignments are reversed. But here we encounter a fundamental operational challenge: the operators $U_G^{(\odot)}$ and $U_N^{(\odot)}$ are defined to act on single-register spaces of dimension 4^n, not on the full dual-register space of dimension 4^{2n}.

The Mathematical Resolution Through Lifting This dimensional mismatch is where lifting becomes indispensable. To construct selective operators that act on one register while leaving the other invariant, we must extend each operator's domain through tensor products with identity operators: $U_G^{(A)} := U_G^{(\odot)} \otimes \mathbb{I}^{(B)}$ and similarly for the others. This lifting procedure preserves the tensor product structure of the total space while enabling register-specific evolution—a mathematical transformation that makes the impossible possible. The true elegance of lifting emerges when we construct the controlled-holosymmetric unitary operator. The control qubit must coherently select between two complete evolutionary scenarios:

$$\boxed{\hat{U}_{\text{holo}} := |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes (U_G^{(A)} \cdot U_N^{(B)}) + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes (U_N^{(A)} \cdot U_G^{(B)}).} \tag{2.68}$$

Without lifting, this construction would be mathematically ill-defined—we would be attempting to combine operators that live in incompatible spaces. The lifted operators, however, all act on the same dual-register space $\mathcal{H}_{\text{RR}}^{(2n)}$, making their coherent superposition not just possible but natural.

From Abstract Computation to the Fabric of Reality This mathematical machinery captures something profound about the nature of reality within the IQR. Unlike conventional quantum computing, which manipulates abstract qubits divorced from physical meaning, the holosymmetric framework operates on Primordial Quantum Singularities ($\mathfrak{B}_x$)—the irreducible quantum seeds from which spacetime itself emerges. These are not computational conveniences but the actual building blocks of reality, each intrinsically characterized by the Quantum Holo-State $|\overset{\circ}{\mathbf{\Psi}}\rangle$ and possessing the full richness of the Fourfold Dialectic Algebra.

When we apply lifted operators like $U_G^{(A)} = U_G^{(\odot)} \otimes \mathbb{I}^{(B)}$, we are orchestrating the evolution of the universe's fundamental constituents. The lifting construction ensures that Register A can undergo coupled parasymmetric evolution, generating internal coherence and entanglement among its constituent PQSs, while Register B remains in stasis. This selective evolution preserves the tensor product structure while enabling each register to follow its own dialectical trajectory.

The Fibered Architecture of Quantum Reality The mathematical space in which these operations unfold is itself revolutionary. Rather than the flat tensor product spaces of conventional quantum mechanics, we work within emergent, fibered Hilbert spaces that reflect the deep geometric structure of reality. The register spaces $\mathcal{H}_{\text{PQS}}^{(n,A)}$ and $\mathcal{H}_{\text{PQS}}^{(n,B)}$ emerge dynamically through the Quantum Holo-State's relational structure, forming part of a Hilbert bundle over the emergent quantum configuration space $\mathcal{X}_q$.

This fibered structure means that when we lift operators to act selectively on registers, we are manipulating the very threads from which the tapestry of spacetime is woven. The identity operator on the inactive register represents the preservation of that register's geometric and modal configuration while its partner undergoes transformation.

Holosymmetry as Quantum Superposition of Universal Histories The most profound aspect emerges when we consider what the control system truly governs. When the control qubit exists in superposition:

$$|\phi_c\rangle = \alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c$$

it places the entire universe of dual registers into a superposition of fundamentally different evolutionary histories. In the $|\mathbf{0}\rangle_c$ branch, Register A undergoes globally coupled evolution while B evolves independently. In the $|\mathbf{1}\rangle_c$ branch, these roles reverse. But in superposition, both histories occur simultaneously, creating interference between different ways the fabric of reality might have woven itself.

This is the operational manifestation of the Holothesis—a mode of being that transcends individual evolutionary paths. Each register maintains its modular independence while the full system encodes relational interference between different evolutionary assignments. The control qubit doesn't merely select between pre-existing possibilities; it enables quantum superposition of fundamentally different ways the universe might organize its internal coherence.

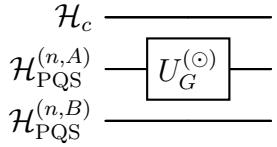
The Physical Process of Lifted Evolution When $U_G^{(A)}$ acts on the dual register state, it generates coupled parasymmetric evolution exclusively within Register A. This is not an abstract transformation but a physical process: the PQSs within Register A develop quantum correlations, their modal states entangle, and coherent superpositions of dialectical modes emerge. Meanwhile, Register B maintains its configuration perfectly, serving as a static reference frame against which Register A's evolution unfolds.

This selective evolution enables something unprecedented: quantum interference between different assignments of physical law. The holosymmetric unitary creates superpositions not just of states but of which regions of the quantum universe evolve under which dynamical principles. Through lifting, we create a mathematical framework where reality itself can exist in superposition—not just superposition of states, but superposition of the very rules by which states evolve.

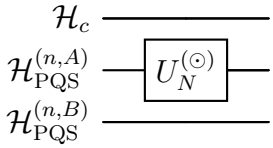
In this light, lifting is elevated from a technical convenience to its true status as the essential mechanism through which holosymmetry achieves its transcendent synthesis. This process enables quantum correlations between entire frameworks of modal evolution, pointing toward a reality whose deepest structure is a quantum superposition of possible law assignments, supplanting the notion of a single, fixed set of laws.

Wiring. Let the control wire carry $\mathcal{H}_c$ in eq. (2.64), and let $\mathbf{d}^{(A)} = (d_{x_1}^{(A)}, \ldots, d_{x_n}^{(A)})$ and $\mathbf{d}^{(B)} = (d_{x_1}^{(B)}, \ldots, d_{x_n}^{(B)})$ denote the $(0,1)$-sector (duality) qubits for Registers A and B inside $\mathcal{H}_{\mathrm{PQS}}^{(n,A)}$ and $\mathcal{H}_{\mathrm{PQS}}^{(n,B)}$, respectively (eqs. (2.61) and (2.62)). All lifted gates act as identity on the orthogonal modal components within each $\mathbb{C}^4$ fibre.

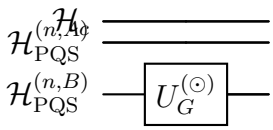
Definition 2.104 (Uncontrolled lifts on the dual space $\mathcal{H}_{\mathrm{RR}}^{(2n)}$)**.** Instantiating Definition 2.103 with the compiled circuits of $U_G^{(\odot)}$ and $U_N^{(\odot)}$ (Definitions 2.66 and 2.85) yields:



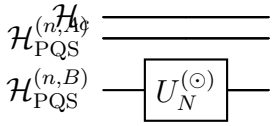
implements $U_G^{(A)} := U_G^{(\odot)} \otimes \mathbb{I}^{(B)}$.



implements $U_N^{(A)} := U_N^{(\odot)} \otimes \mathbb{I}^{(B)}$.



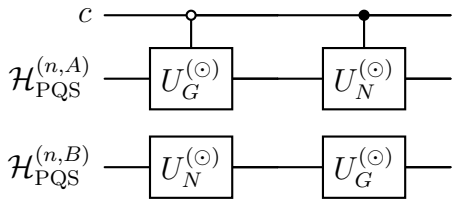
implements $U_G^{(B)} := \mathbb{I}^{(A)} \otimes U_G^{(\odot)}$.



implements $U_N^{(B)} := \mathbb{I}^{(A)} \otimes U_N^{(\odot)}$.

Here each block stands for the full multi-qubit implementation compiled earlier (local R_z/R_x layers, XY exchange pairs, and global flags, as applicable).

Definition 2.105 (Controlled lifted assignment (*holosymmetric switch*))**.** Realize eq. (2.65) on $\mathcal{H}_{\mathrm{Holo}}$ by conditioning on the control qubit: when $|\mathbf{0}\rangle_c$, apply ($U_G^{(\odot)}$ on A)$\otimes$($U_N^{(\odot)}$ on B); when $|\mathbf{1}\rangle_c$, apply ($U_N^{(\odot)}$ on A)$\otimes$($U_G^{(\odot)}$ on B). Using open/closed controls,



This two-layer multiplexor implements the block-diagonal unitary $|\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \left(U_G^{(A)} U_N^{(B)}\right) + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \left(U_N^{(A)} U_G^{(B)}\right)$, as required by Definition 2.102.

Definition 2.106 (Lifted parasymmetric effects (Naimark flags on one register))**.** Let $V_+^{(A)}$ (resp. $V_+^{(B)}$) prepare $|\Psi_{\mathrm{para}}^{(n)}\rangle$ on $\mathbf{d}^{(A)}$ (resp. $\mathbf{d}^{(B)}$). Then $P_{\mathrm{para}}^{(x_1^{(A)} \ldots x_n^{(A)})} \otimes \mathbb{I}^{(B)}$ and $\mathbb{I}^{(A)} \otimes P_{\mathrm{para}}^{(x_1^{(B)} \ldots x_n^{(B)})}$ (eq. (2.59)) are realized by:

Remark 2.107 (Compatibility with holosymmetric superposition)**.** The lifted unitaries of Definition 2.104 and the controlled multiplexor in Definition 2.105 act on disjoint tensor factors of $\mathcal{H}_{\mathrm{Holo}}$ (eq. (2.62)), thereby preserving the factorized structure required for coherent superpositions of dynamical histories in Definition 2.102.

Register–selective action. Lifted parasymmetric unitaries act by transplanting a single–register evolution onto one register while leaving the other invariant. Concretely, $U_G^{(A)} := U_G^{(\odot)} \otimes \mathbb{I}^{(B)}$ and $U_N^{(B)} := \mathbb{I}^{(A)} \otimes U_N^{(\odot)}$ (and the analogous variants) implement within the addressed register exactly the unified global coupled or the composite decoupled dynamics compiled in Definitions 2.66 and 2.85, and act as identity on the spectator register, as formalized

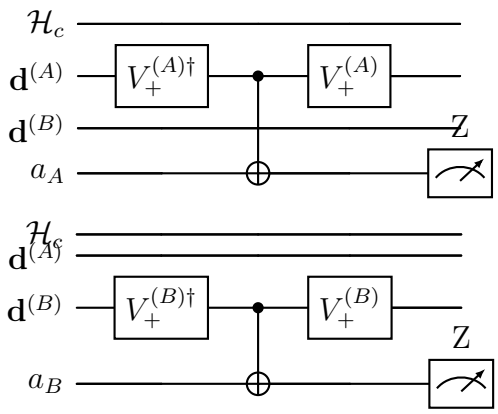


Figure 2.1: Ancilla outcomes $a_A = 1$ or $a_B = 1$ implement the corresponding lifted projector; coherent flags are obtained by omitting the measurement and uncomputing.

in Definition 2.103. Operationally, these lifts steer the single–excitation parasymmetric amplitude—transporting, phasing, and mixing it via XY–exchange and modal–class phase drives—only inside the targeted register.

Entanglement locality and tensorial integrity. Because each lifted gate is tensored with the identity on the complementary register, it cannot create (or destroy) inter–register entanglement; it reshapes correlations solely within the acted–upon register. Hence the dual–register tensor product structure of eqs. (2.61) and (2.62) is preserved throughout. In particular, parasymmetric patterns such as the W–type synthesis subspace remain confined to the addressed register, while the other register retains its prior state.

Holosymmetric switching via coherent control. The holosymmetric control qubit of Definition 2.102 implements a coherent multiplexing of lifted evolutions according to the assignment basis in eq. (2.65). Prepared in a superposition, the control effects a superposition of *dynamical histories*: "A entangled/B decoupled" and "A decoupled/B entangled" are applied in parallel and subsequently interfere. Thus holosymmetry promotes interference from states to *assignments of evolutions*, providing the operational heart of the holosymmetric sector.

Lifted parasymmetric effects as localized coherence filters. Lifted projectors realized by Naimark–flag constructions act as register–local coherence filters. Using the global parasymmetric state and projector of eq. (2.59), the circuits flag $P_{\text{para}}^{(x_1^{(A)}\ldots x_n^{(A)})} \otimes \mathbb{I}^{(B)}$ or $\mathbb{I}^{(A)} \otimes P_{\text{para}}^{(x_1^{(B)}\ldots x_n^{(B)})}$ without disturbing the spectator register. Combined with the holosymmetric switch, these effects enable post–selection, phase–kickback, and comparison of synthesis across registers while maintaining compatibility with eq. (2.62).

Summary. Lifted parasymmetric operators provide register–addressable control of synthesis within the dual–register architecture: they steer, preserve, and phase parasymmetric coherence in one register while leaving the other untouched (Definition 2.103). Coupled with the

control–conditioned multiplexing of Definition 2.102, they elevate parasymmetric processing to holosymmetry, wherein distinct lifted evolutions coexist in coherent superposition and interfere at the level of full modal histories.

Definition 2.108 (Parallel Path Operators for Dual PQS Configurations)**.** Let the dual register Hilbert space be denoted by $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ (eq. (2.61)). Let $U_G^{(A)}$, $U_N^{(A)}$, $U_G^{(B)}$, and $U_N^{(B)}$ be the lifted parasymmetric operators as defined in Definition 2.103, corresponding to the unified global coupled evolution (Definition 2.85) and the generalized composite decoupled evolution (Definition 2.66).

We define two distinct, complete, and unitary evolutionary pathways for the dual register system:

1. **Path 1 (Coupled-A / Decoupled-B):** This pathway describes a scenario where Register A undergoes fully coupled evolution while Register B evolves under a factorized, decoupled dynamic. It is represented by the operator:

$$\boxed{\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} := U_G^{(A)} \cdot U_N^{(B)}.} \tag{2.69}$$

   This operator places complex, entangling dynamics on Register A while preserving the modular coherence structure of Register B.

2. **Path 2 (Decoupled-A / Coupled-B):** This is the complementary pathway, where Register A evolves under decoupled dynamics while Register B undergoes fully coupled evolution. It is represented by:

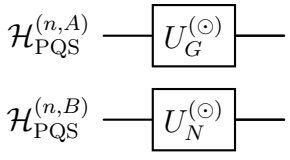
$$\boxed{\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} := U_N^{(A)} \cdot U_G^{(B)}.} \tag{2.70}$$

   Here, the roles are reversed, with Register B being the locus of non-separable, holistic evolution.

Physical Significance. Each operator $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ is a unitary operator on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$, representing a distinct, physically realizable evolutionary history for the dual register system. They serve as the foundational "paths" that are placed into coherent superposition by the holosymmetric control system, enabling the study of quantum interference between different dynamical laws.

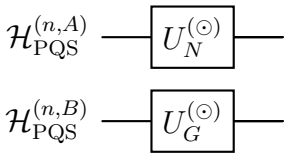
Wiring convention. A single wire labeled $\mathcal{H}_{\mathrm{PQS}}^{(n,A)}$ (resp. $\mathcal{H}_{\mathrm{PQS}}^{(n,B)}$) denotes the entire n-site register in eq. (2.61). A boxed gate on that wire stands for the multi-qubit implementation compiled earlier for the corresponding operator.

Definition 2.109 (Path 1 circuit: Coupled–A / Decoupled–B)**.** This realizes $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} = U_G^{(A)} U_N^{(B)}$ of eq. (2.69):



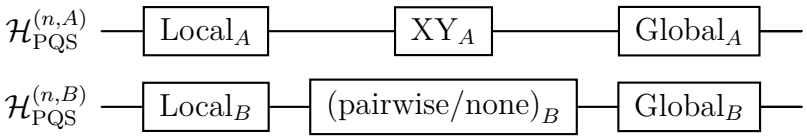
Here $U_G^{(\odot)}$ is the unified global coupled evolution and $U_N^{(\odot)}$ is the composite decoupled evolution (Definitions 2.66 and 2.85). Since the registers are disjoint, the two blocks may be executed in parallel.

Definition 2.110 (Path 2 circuit: Decoupled–A / Coupled–B)**.** This realizes $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} = U_N^{(A)} U_G^{(B)}$ of eq. (2.70):



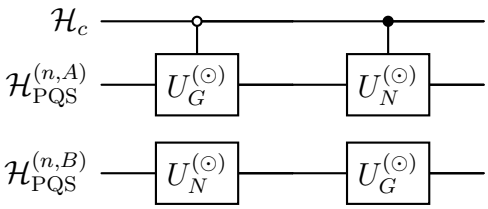
Again, the two multi-qubit blocks act on disjoint tensor factors and commute.

Remark 2.111 (Expanded (one Trotter slice) view for each path)**.** If $U_G^{(\odot)}$ and $U_N^{(\odot)}$ are implemented via first/second-order Trotterization, a single slice of Path 1 can be drawn schematically by expanding each block into its constituent layers (local rotations, XY–exchange pairs, global modal-class flags), all in parallel across registers:



where the A-row layers instantiate the unified global coupled construction and the B-row layers instantiate the composite decoupled construction (Definitions 2.66 and 2.85). Path 2 is identical with A/B rows swapped. Repeating the slice r times yields the full Trotterized evolution for eqs. (2.69) and (2.70).

Remark 2.112 (Holosymmetric control wrapper (optional))**.** To place the two paths into coherent superposition as in Definition 2.102, prepend a control wire $\mathcal{H}_c$ and condition the assignment according to eq. (2.65):



The first (open-control) column realizes eq. (2.69) on the registers for $|\mathbf{0}\rangle_c$, the second (closed-control) column realizes eq. (2.70) for $|\mathbf{1}\rangle_c$.

Overview. The parallel path circuits enact two unitary, register-selective evolutions on the dual PQS architecture of eqs. (2.61) and (2.62). Each evolution is formed by *lifting* previously defined parasymmetric dynamics to a chosen register while the other register remains invariant (Definition 2.103). The result is a pair of complete, physically distinct histories, each realized as a product of multi–qubit operations confined to one register factor at a time (Definition 2.108).

Path 1 vs. Path 2. In *Path 1* (eq. (2.69)), Register A undergoes the unified global coupled evolution $U_G^{(A)}$ while Register B experiences the composite decoupled evolution $U_N^{(B)}$ (Definitions 2.66 and 2.85). This places entangling, exchange–type transport and modal–class phasing within A, and factorized, sitewise dynamics within B. In the complementary *Path 2* (eq. (2.70)), the roles are reversed: Register B hosts the globally coupled synthesis while Register A evolves in a decoupled manner. Because the registers occupy disjoint tensor factors, the two blockwise evolutions commute and can be executed in parallel without inter–register crosstalk.

Coherent switching and interference. The holosymmetric control system of Definition 2.102 coherently assigns these paths by conditioning on the control basis of eq. (2.65). Prepared in a superposition, the control implements a superposition of full evolutions—"A coupled/B decoupled" *and* "A decoupled/B coupled"—so that the resulting histories interfere. In this way, holosymmetry promotes interference from static states to *assignments of dynamics*, enabling operational comparisons between coupled and decoupled parasymmetric laws within the same unified protocol.

Local coherence tests. Register-local parasymmetric effects are realized by lifted Naimark-flag projectors that act on one register while leaving the other untouched (cf. eq. (2.59) and Definition 2.103). These flags serve as localized coherence filters—e.g., tests for the global parasymmetric subspace in A or in B—and are compatible with either path as well as with the control-conditioned superposition. Hence they support post-selection and phase-kickback procedures without disturbing the spectator register.

Summary. The parallel path circuits implement two complementary, unitary histories on the dual PQS registers (Definition 2.108): one with globally coupled synthesis in A and decoupled evolution in B, and the other with the assignments reversed. A coherent control realizes their superposition and interference, while lifted projectors provide register–local diagnostics, together furnishing a holosymmetric scheme that steers, contrasts, and coherently compares parasymmetric dynamics across the dual–register architecture.

Intuitive picture. Consider two separate ensembles of quantum "lights": Register A and Register B. The *controlled holosymmetric operator* acts as a smart switch, governed by a tiny control light (the control qubit), that decides which ensemble performs a complex, highly coordinated choreography (the *coupled* evolution) and which ensemble proceeds with simple, independent motion (the *decoupled* evolution).

Branch selection. If the control light is 0, the switch routes the coupled choreography to Register A and the decoupled routine to Register B (Path 1). If the control light is 1, the assignments are swapped: Register B receives the coupled choreography while Register A runs decoupled (Path 2). Because the two ensembles are separate, these routines can be applied side by side without interfering; the switch simply directs which routine lands where.

Superposition and interference. When the control light is prepared in a "both-at-once" state (a quantum superposition), the full system simultaneously follows the two histories: "A-coupled/B-decoupled" *and* "A-decoupled/B-coupled." Afterward, the control light is rotated back and read out, converting the quiet tug-of-war between the histories into a visible difference in outcomes. In effect, the circuit allows two alternative worldlines of the same system to overlap and *interfere*, revealing how the choice of choreography (who coordinates, who does not) changes collective behavior.

Efficient realization. An efficiency trick replaces two large, separate switches with a baseline-plus-correction strategy: first apply one full routine to both ensembles as a baseline; then—only if the control is 1—apply a single correction that transforms the baseline into the alternative history. Functionally this remains the same smart switch, packaged more compactly.

Bottom line. The controlled holosymmetric operator is a *coherent selector* of dynamical stories. It assigns complex coordination to one register and simplicity to the other, or the reverse—and, crucially, it can place those assignments into quantum superposition so their consequences can be compared through interference.

Joint State of the Dual Primordial Registers

Definition 2.113 (Joint State of the Dual Primordial Registers)**.** Let $\mathcal{H}_{\mathrm{PQS}}^{(n,A)}$ and $\mathcal{H}_{\mathrm{PQS}}^{(n,B)}$ denote the Hilbert spaces associated with two n-PQS registers—Register A and Register B—each comprising n Primordial Quantum Singularities. Define the dual-register Hilbert space as:

$$\mathcal{H}_{\mathrm{RR}}^{(2n)} := \mathcal{H}_{\mathrm{PQS}}^{(n,A)} \otimes \mathcal{H}_{\mathrm{PQS}}^{(n,B)}. \tag{2.71}$$

Then the state vector:

$$\boxed{|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}} \tag{2.72}$$

is called the *joint quantum state of the dual PQS registers*. It encodes the full quantum configuration of both registers, including all modal amplitudes, internal correlations, and possible inter-register entanglement. This state serves as the initial condition for holosymmetric evolution in the interferometric framework.

Branch Decomposition by Control State

The holosymmetric Hilbert space $\mathcal{H}_{\mathrm{Holo}}$ decomposes naturally into two orthogonal branches, each determined by the control qubit and corresponding to a distinct dynamical pathway:

$$\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_{\mathrm{Holo}}^{A_G B_N} \oplus \mathcal{H}_{\mathrm{Holo}}^{A_N B_G},$$

where:

$$\boxed{\mathcal{H}_{\mathrm{Holo}}^{A_G B_N} := \mathrm{span}\{|\mathbf{0}\rangle_c\} \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)},} \tag{2.73}$$

$$\boxed{\mathcal{H}_{\mathrm{Holo}}^{A_N B_G} := \mathrm{span}\{|\mathbf{1}\rangle_c\} \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}.} \tag{2.74}$$

The control state $|\mathbf{0}\rangle_c$ selects the operator $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, in which Register A evolves under fully coupled dynamics $U_G^{(A)}$, and Register B evolves under generalized decoupled dynamics $U_N^{(B)}$. Conversely, control state $|\mathbf{1}\rangle_c$ activates the operator $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, reversing this assignment.

Superposed Evolution. When the control qubit is placed in a coherent superposition,

$$|\phi_c\rangle = \alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c, \quad \alpha, \beta \in \mathbb{C},\ |\alpha|^2 + |\beta|^2 = 1,$$

the resulting evolution involves an entangled superposition of parallel dynamical trajectories:

$$|\Psi_{\mathrm{Holo}}\rangle = \alpha\,|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right) + \beta\,|\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right).$$

This expresses a genuinely holosymmetric interference between relational evolutions applied across dual PQS registers—constituting a higher-order modality of dynamical synthesis.

2.3.2 Holosymmetry Component Operators

The complete holosymmetric transformation, denoted generically as $\mathbf{U}_{\mathrm{Holo}}$, is a unitary operator designed to act on the full emergent Hilbert space for holosymmetry,

$$\mathcal{H}_{\mathrm{Holo}} := \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{PQS}}^{(n,A)} \otimes \mathcal{H}_{\mathrm{PQS}}^{(n,B)} \cong \mathbb{C}^{2^{4n+1}},$$

as defined in eq. (2.62). This space includes:

- the **control system** $\mathcal{H}_c$ (Definition 2.102),
- and the **dual register space** $\mathcal{H}_{\mathrm{RR}}^{(2n)} := \mathcal{H}_{\mathrm{PQS}}^{(n,A)} \otimes \mathcal{H}_{\mathrm{PQS}}^{(n,B)}$ (eq. (2.61)).

We now explore operators capable of enacting holosymmetric evolution, beginning with a controlled-path construction.

The Controlled Holosymmetric Operator ($\mathbf{U}_{\mathrm{ctrl}}$)

The first candidate for holosymmetric evolution is a *controlled unitary operator*, denoted $\mathbf{U}_{\mathrm{ctrl}}$. It selects between two distinct parasymmetric evolutionary paths—namely:

- $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$: coupled evolution on Register A and decoupled on Register B (eq. (2.69)),
- $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$: decoupled evolution on Register A and coupled on Register B (eq. (2.70)),

based on the state of the control qubit $\mathcal{H}_c$.

Definition 2.114 (Controlled Holosymmetric Operator)**.** The *Controlled Holosymmetric Operator* $\mathbf{U}_{\mathrm{ctrl}}$ is defined as the following unitary operator on the full holosymmetric Hilbert space $\mathcal{H}_{\mathrm{Holo}}$:

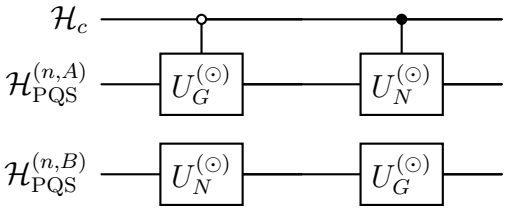
$$\boxed{\mathbf{U}_{\mathrm{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.} \tag{2.75}$$

Here:

- $|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c \in \mathcal{H}_c$ form the orthonormal basis of the control Hilbert space,
- $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ are the parallel path operators acting on the dual PQS register space $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ (Definition 2.108).

This operator implements holosymmetric branching at the dynamical level: when the control system is in a coherent superposition $\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c$, the global evolution of the system reflects a quantum superposition of distinct dynamical regimes across the two registers.

Definition 2.115 (Direct controlled-path realization of $\mathbf{U}_{\mathrm{ctrl}}$)**.** Instantiating eq. (2.75) with the path unitaries of eqs. (2.69) and (2.70) yields the following *two-branch multiplexer* on $\mathcal{H}_{\mathrm{Holo}}$ (eq. (2.62)):



The first (open–control) column realizes $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ when the control is $|\mathbf{0}\rangle_c$ (eq. (2.73)), and the second (closed–control) column realizes $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ when the control is $|\mathbf{1}\rangle_c$ (eq. (2.74)). The blocks $U_G^{(\odot)}$ and $U_N^{(\odot)}$ are the compiled multi–qubit evolutions from Definitions 2.66 and 2.85.

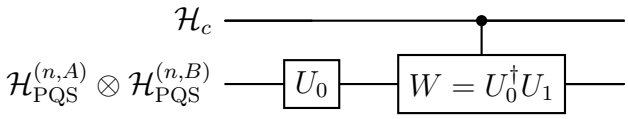
Definition 2.116 (Canonical synthesis with a single controlled correction)**.** Let

$$U_0 \;:=\; \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \qquad U_1 \;:=\; \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}, \qquad W \;:=\; U_0^\dagger U_1.$$

Then $\mathbf{U}_{\mathrm{ctrl}}$ admits the block form

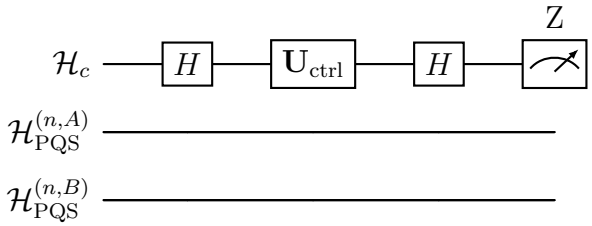
$$\boxed{\mathbf{U}_{\mathrm{ctrl}} = \Big(|\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \mathbb{I} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes W \Big)\,(\mathbb{I}_c \otimes U_0),} \tag{2.76}$$

which is implemented by an *unconditional* U_0 followed by a *single* $|\mathbf{1}\rangle$–controlled W:



This synthesis is often depth–optimal when U_0 and U_1 are available as primitives and W can be compiled efficiently from them.

Definition 2.117 (Hadamard–conjugated wrapper for branch interference)**.** To realize the superposed evolution of Section 2.3.1, prepare and read out the control in the X basis:



The first H prepares $\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c$, $\mathbf{U}_{\mathrm{ctrl}}$ enacts the branch–conditioned paths of eqs. (2.69) and (2.70), and the final H converts branch interference into Z–basis statistics on the control.

Remark 2.118 (Compilation notes)**.** (i) In Definition 2.115, the two branch blocks may be executed in parallel across the disjoint register wires, since they act on different tensor factors of $\mathcal{H}_{\mathrm{RR}}^{(2n)}$. (ii) In Definition 2.116, the controlled W acts jointly on both registers; when $U_G^{(\odot)}$ and $U_N^{(\odot)}$ are Trotterized, W inherits the same layered structure (local rotations, XY exchanges, global flags) and can be compiled by palindromic cancellation of common layers.

Operational role. The controlled holosymmetric operator $\mathbf{U}_{\mathrm{ctrl}}$ is a coherent, register–selective path selector acting on the full holosymmetric space $\mathcal{H}_{\mathrm{Holo}}$ (eq. (2.62)). By definition (eq. (2.75)), the control basis state fixes which parallel path acts on the dual register factor $\mathcal{H}_{\mathrm{RR}}^{(2n)}$: the branch $|\mathbf{0}\rangle_c$ selects $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and the branch $|\mathbf{1}\rangle_c$ selects $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, with the branch subspaces given in eqs. (2.73) and (2.74).

Branch behavior. Under $|\mathbf{0}\rangle_c$, the operator implements *Path 1* (eq. (2.69)): Register A is driven by the unified global coupled evolution $U_G^{(A)}$, while Register B undergoes the composite decoupled evolution $U_N^{(B)}$ (Definitions 2.66 and 2.85). Under $|\mathbf{1}\rangle_c$, *Path 2* is enacted (eq. (2.70)), reversing the assignments. Because these lifted gates act on disjoint tensor factors, the two large register operations commute and may be executed side–by–side without inter–register crosstalk (Definition 2.108).

Superposed evolution and interference. Preparing the control in a coherent superposition yields the superposed evolution of Section 2.3.1: the global state evolves as a controlled superposition of the two complete histories, $|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} |\Psi_{\mathrm{RR}}\rangle$ and $|\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} |\Psi_{\mathrm{RR}}\rangle$. Conjugating $\mathbf{U}_{\mathrm{ctrl}}$ by Hadamards on the control (prepare and read in the X basis) converts branch interference into observable Z–basis statistics on the control, operationalizing holosymmetric comparison between the two dynamical laws (eq. (2.75)).

Canonical synthesis. A depth–efficient realization follows the block form of eq. (2.76): apply one path unconditionally as a baseline ($U_0 = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$), then apply the single controlled correction $W = U_0^\dagger U_1$ (with $U_1 = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$) conditioned on $|\mathbf{1}\rangle_c$. When $U_G^{(\odot)}$ and $U_N^{(\odot)}$ are compiled in layered/Trotterized form, W inherits the same structure and can be synthesized by canceling common layers (Definitions 2.66 and 2.85).

Summary. The controlled holosymmetric operator is a coherent selector of register–level evolutions: it assigns the globally coupled parasymmetric dynamics to one register and the decoupled dynamics to the other, or vice versa, according to the control branch (eqs. (2.69), (2.70) and (2.75)). With the control in superposition, the construction promotes interference from states to *assignments of dynamics*, enabling holosymmetric tests and comparisons on $\mathcal{H}_{\mathrm{Holo}}$ that respect the dual–register tensor structure (eq. (2.62)).

Block Matrix Form

Relative to the control-resolved branch decomposition

$$\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_{[\mathbf{0}]}^{A_G B_N} \oplus \mathcal{H}_{[\mathbf{1}]}^{A_N B_G},$$

(Section 2.3.1), where:

$$\mathcal{H}_{\text{Holo}}^{A_G B_N} := \text{span}\{|\mathbf{0}\rangle_c\} \otimes \mathcal{H}_{\text{RR}}^{(2n)},$$
$$\mathcal{H}_{\text{Holo}}^{A_N B_G} := \text{span}\{|\mathbf{1}\rangle_c\} \otimes \mathcal{H}_{\text{RR}}^{(2n)},$$

the controlled holosymmetric operator $\mathbf{U}_{\text{ctrl}}$ (Definition 2.114) takes the following block-diagonal form:

$$\boxed{\mathbf{U}_{\text{ctrl}} = \begin{pmatrix} \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} & \mathbf{0} \\ \mathbf{0} & \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \end{pmatrix}.} \tag{2.77}$$

Here:

- $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} := U_G^{(A)} \cdot U_N^{(B)}$ is the lifted operator implementing **coupled** evolution on Register A and **decoupled** on Register B (eq. (2.69)),
- $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} := U_N^{(A)} \cdot U_G^{(B)}$ is the complementary lifted operator for **decoupled** A and **coupled** B (eq. (2.70)),
- $\mathbf{0}$ denotes the zero operator acting between orthogonal control branches.

Interpretation. This block structure reflects the conditional application of distinct parasymmetric dynamics to the PQS system depending on the control register. When the control is in a definite state $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$, the evolution is purely confined to the corresponding block. In coherent superposition, both blocks contribute simultaneously, realizing holosymmetric interference between two full dynamical pathways.

Justification. From the definition:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

we are expressing a **controlled unitary** operator acting on the total holosymmetric Hilbert space:

$$\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)} \cong \mathcal{H}_{\text{Holo}}^{A_G B_N} \oplus \mathcal{H}_{\text{Holo}}^{A_N B_G}.$$

Then, under this orthogonal decomposition, $\mathbf{U}_{\text{ctrl}}$ acts as:

$$\mathbf{U}_{\text{ctrl}} = \begin{pmatrix} \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} & \mathbf{0} \\ \mathbf{0} & \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \end{pmatrix},$$

which is the canonical matrix representation of a controlled unitary in the computational basis for $\mathcal{H}_c$. Each block corresponds precisely to the action conditioned on the control state $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$, respectively.

Action on Control Basis States

If the initial state of the dual PQS registers is $|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}$, the action of the controlled holosymmetric operator $\mathbf{U}_{\mathrm{ctrl}}$ on product states with definite control states is:

$$\mathbf{U}_{\mathrm{ctrl}}\left(|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle\right) = |\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right),$$
$$\mathbf{U}_{\mathrm{ctrl}}\left(|\mathbf{1}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle\right) = |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right).$$

Interpretation of the Operator $\mathbf{U}_{\mathrm{ctrl}}$

The Controlled Holosymmetric Operator $\mathbf{U}_{\mathrm{ctrl}}$ functions as a *quantum multiplexer*—a programmable quantum switch that places the dual PQS registers $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ under the coherent governance of a two-level quantum control system $\mathcal{H}_c$. This control enables two distinct operational regimes: one classical, one intrinsically quantum.

1. Classical Analogue: A Deterministic Switch When the control system is initialized in a definite computational basis state—either $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$—its role mirrors that of a classical 'IF-THEN-ELSE' logic gate:

- *If Control is $|\mathbf{0}\rangle_c$:* The operator deterministically applies the evolution $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, corresponding to **coupled** dynamics on Register A and **decoupled** dynamics on Register B.
- *If Control is $|\mathbf{1}\rangle_c$:* The operator selects the complementary evolution $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, applying **decoupled** dynamics on Register A and **coupled** on Register B.

In this classical-control regime, the system follows a single, definite pathway with no entanglement generated between control and register subsystems. The result is a clean partitioning of dynamics based on a known control input—a classical branching architecture instantiated in quantum logic.

2. Quantum Engine: A Superposition of Histories The true power of $\mathbf{U}_{\mathrm{ctrl}}$ is unleashed when the control system is prepared in a *superposition* of its basis states, such as $\frac{1}{\sqrt{2}}(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c)$. In this regime, the operator transcends its classical analogue and becomes an engine for generating coherent quantum superpositions.

- *Quantum Parallelism:* Rather than selecting a single dynamical branch, the operator enacts *both* evolutionary pathways in superposition. The system evolves into a coherent sum:

$$\mathbf{U}_{\mathrm{ctrl}}\left(\frac{1}{\sqrt{2}}(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle\right) = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right).$$

  This is a manifestation of quantum parallelism: multiple dynamical histories coexist within a single entangled state.

- *Entanglement as a Record:* The resulting state is necessarily *entangled* between the control and register subsystems. The $|\mathbf{0}\rangle_c$ component is correlated with the outcome of evolution along the $A_G B_N$ branch, and the $|\mathbf{1}\rangle_c$ component with the $A_N B_G$ branch. This entanglement encodes a *coherent record* of the alternative quantum histories, incarnated as statistical mixtures and as a unified quantum object.

Measuring the control qubit after evolution collapses this superposition, forcing the system into one of the distinct branches and revealing the corresponding register state. In this sense, $\mathbf{U}_{\text{ctrl}}$ serves as a foundational mechanism for generating and manipulating *entangled history states*, a key theoretical resource in quantum simulation, algorithm design, and holosymmetric inference.

Structural Insight: Architect of a Quantum Interferometer

Structurally, the controlled holosymmetric operator $\mathbf{U}_{\text{ctrl}}$ does more than simply toggle between two dynamical evolutions; it serves as the foundational component for constructing a *quantum interferometer*. Its essential function is to initiate a *controlled holosymmetric bifurcation*—a quantum fork that splits the register system into two coherently evolving trajectories.

This bifurcation represents the first phase of a two-stage interferometric architecture:

1. *Path Creation (Act I):* Enacted by $\mathbf{U}_{\text{ctrl}}$, this phase leverages a superposed control qubit to generate two simultaneous quantum histories. One branch evolves under $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$, the other under $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$. Each history is coherently labeled by its respective control state: $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$.

2. *Path Recombination and Interference (Act II):* These bifurcated trajectories are not endpoints but resources. A subsequent operation—analogous to the second beam splitter in a Mach-Zehnder interferometer—is used to recombine the control paths. When the two branches are coherently merged, quantum interference arises.

The potency of this structure lies in the interference outcome, which is exquisitely sensitive to the *path differential* between the two dynamical evolutions. Specifically, it depends on how $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ differ in phase and amplitude transformations.

Thus, $\mathbf{U}_{\text{ctrl}}$ is not just a switch—it is the architectural nucleus that constructs the key interferometric resource: a coherent superposition of divergent evolutions. By enabling their subsequent recombination, the framework extracts holosymmetric interference signatures that act as sensitive probes into the structural contrast between competing dynamical regimes acting on the quantum system.

Interferometer Component	Holosymmetry Analogue	Function
Initial Light Beam	$\|\psi\rangle_c \otimes \|\Psi_{\mathrm{RR}}\rangle$	System prior to path bifurcation
First Beam Splitter	$\mathbf{U}_{\mathrm{ctrl}}$	Creates controlled bifurcation into entangled dynamical branches
Path A vs. Path B	$\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ vs. $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$	Distinct holosymmetric evolutions of the PQS registers
Phase Shifter	$\Delta\hat{\mathbf{U}} := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$	Encodes relative phase/amplitude difference between pathways
Second Beam Splitter	$\mathbf{U}_{\mathrm{recomb}}$	Coherently recombines the bifurcated control branches
Interference at Detectors	Final measurement on $\mathcal{H}_c$	Reveals holosymmetric interference signature

Table 2.1: Mapping Between Interferometric Components and Holosymmetric Structures

The Hadamard-Style Holosymmetric Combination ($\mathbf{U}_{\mathrm{Had}}$)

The operator $\mathbf{U}_{\mathrm{Had}}$ embodies a refined form of holosymmetric evolution that is explicitly engineered to expose quantum interference between the distinct dynamical histories associated with $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ (eqs. (2.69) and (2.70)). By conjugating the Controlled Holosymmetric Operator $\mathbf{U}_{\mathrm{ctrl}}$ with Hadamard operations on the control qubit, $\mathbf{U}_{\mathrm{Had}}$ both prepares and recombines coherent control superpositions.

Definition 2.119 (Hadamard-Conjugated Holosymmetry Operator)**.** We define the *Hadamard-Conjugated Holosymmetry* Operator, $\mathbf{U}_{\mathrm{Had}}$, which acts on the full holosymmetric Hilbert space $\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$.

$$
\begin{aligned}
\mathbf{U}_{\mathrm{Had}} &:= (H_c \otimes I_{\mathrm{RR}}^{(2n)})\ \mathbf{U}_{\mathrm{ctrl}}\ (H_c \otimes I_{\mathrm{RR}}^{(2n)}) \\
&= (H_c \otimes I_{\mathrm{RR}}^{(2n)})\ \left[|\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right]\ (H_c \otimes I_{\mathrm{RR}}^{(2n)}) \\
&= \left[(H_c|\mathbf{0}\rangle_c)(\langle\mathbf{0}|_c H_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + (H_c|\mathbf{1}\rangle_c)(\langle\mathbf{1}|_c H_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right] \\
&= \left[|+\rangle_c\langle+|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |-\rangle_c\langle-|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right],
\end{aligned}
\tag{2.78}
$$

where:

- H_c is the Hadamard operator acting on the control Hilbert space $\mathcal{H}_c$,

- $I_{\mathrm{RR}}^{(2n)}$ is the identity operator on the dual register space $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ (eq. (2.61)),
- $\mathbf{U}_{\mathrm{ctrl}}$ is the Contracted Holosymmetric Operator (Definition 2.114).

The purpose of this operator is to enact a complete interferometric cycle: it prepares a coherent control superposition, evolves the system through bifurcated holosymmetric dynamics, and recombines the pathways to reveal interference effects that encode the contrast between the alternative evolutions. Since both the Hadamard operator and the controlled unitary operator are unitary ($H_c = H_c^\dagger$, $H_c^2 = I_c$), the composite operator $\mathbf{U}_{\mathrm{Had}}$ is also manifestly unitary.

Block Matrix Form. In the computational basis $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$ of the control Hilbert space $\mathcal{H}_c$, the Hadamard operator is given by:

$$H_c = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

Given that the controlled holosymmetric operator $\mathbf{U}_{\mathrm{ctrl}}$ acts as a block-diagonal matrix:

$$\mathbf{U}_{\mathrm{ctrl}} = \begin{pmatrix} \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} & \mathbf{0} \\ \mathbf{0} & \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \end{pmatrix},$$

its Hadamard-conjugated form $\mathbf{U}_{\mathrm{Had}} := (H_c \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (H_c \otimes I)$ can be computed explicitly as:

$$\mathbf{U}_{\mathrm{Had}} = \frac{1}{2} \begin{pmatrix} \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} & \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \\ \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} & \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \end{pmatrix}.$$

Each entry in this matrix is itself an operator acting on the dual register space $\mathcal{H}_{\mathrm{RR}}^{(2n)}$. The off-diagonal blocks encode the interference between the two holosymmetric branches, and vanish only when the dynamics $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ are identical. The diagonal blocks represent the coherent superposition of both dynamical evolutions.

Action on Control Basis States. Let $|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}$ be an arbitrary state of the dual PQS registers. The action of the Hadamard-conjugated holosymmetric operator $\mathbf{U}_{\mathrm{Had}}$ on the product basis states of the full holosymmetric Hilbert space $\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$ follows directly from its definition:

$$\mathbf{U}_{\mathrm{Had}} := (H_c \otimes I_{\mathrm{RR}}^{(2n)})\ \mathbf{U}_{\mathrm{ctrl}}\ (H_c \otimes I_{\mathrm{RR}}^{(2n)}).$$

Case 1: Action on $|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle$

$$\begin{aligned}
\mathbf{U}_{\mathrm{Had}}\,(|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle) &= (H_c \otimes I_{\mathrm{RR}}^{(2n)})\ \mathbf{U}_{\mathrm{ctrl}}\ (H_c|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle) \\
&= (H_c \otimes I)\ \mathbf{U}_{\mathrm{ctrl}}\ \left(\tfrac{1}{\sqrt{2}}(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle\right) \\
&= (H_c \otimes I)\ \tfrac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right) \\
&= \tfrac{1}{2}\left[(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle + (|\mathbf{0}\rangle_c - |\mathbf{1}\rangle_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right] \\
&= \tfrac{1}{2}\Big[|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle \\
&\qquad + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle\Big].
\end{aligned}$$

Case 2: Action on $|\mathbf{1}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle$

$$\begin{aligned}
\mathbf{U}_{\mathrm{Had}}\left(|\mathbf{1}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle\right) &= \left(H_c \otimes I_{\mathrm{RR}}^{(2n)}\right)\, \mathbf{U}_{\mathrm{ctrl}}\ \left(H_c|\mathbf{1}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle\right) \\
&= \left(H_c \otimes I\right)\, \mathbf{U}_{\mathrm{ctrl}}\ \left(\tfrac{1}{\sqrt{2}}(|\mathbf{0}\rangle_c - |\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle\right) \\
&= \tfrac{1}{2}\left[(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle - (|\mathbf{0}\rangle_c - |\mathbf{1}\rangle_c) \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle\right] \\
&= \tfrac{1}{2}\Big[|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle \\
&\qquad + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle\Big].
\end{aligned}$$

General Action The general action of the Hadamard-conjugated holosymmetric operator is then given by:

$$\begin{aligned}
\mathbf{U}_{\mathrm{Had}}\left((\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle\right) = \tfrac{1}{2}|\mathbf{0}\rangle_c \otimes \left[(\alpha+\beta)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + (\alpha-\beta)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right]|\Psi_{\mathrm{RR}}\rangle \\
+ \tfrac{1}{2}|\mathbf{1}\rangle_c \otimes \left[(\alpha+\beta)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} + (\alpha-\beta)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}\right]|\Psi_{\mathrm{RR}}\rangle.
\end{aligned} \tag{2.79}$$

Interpretation and Significance of $\mathbf{U}_{\mathrm{Had}}$ The operator $\mathbf{U}_{\mathrm{Had}}$ elevates the concept of holosymmetry from a simple conditional switch to a complete, self-contained *quantum interferometer*. Its structure, defined by conjugating the controlled evolution $\mathbf{U}_{\mathrm{ctrl}}$ with Hadamard gates on the control system, is the canonical circuit for probing the interference between alternative quantum histories. The entire operation can be understood as a three-act process.

The Quantum Interferometer Circuit The action of $\mathbf{U}_{\mathrm{Had}}$ on an initial state like $|\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle$ perfectly maps to the function of a Mach-Zehnder interferometer.

Act I: Path Creation (First H_c) The initial Hadamard gate acts as the *first beam splitter*. It transforms the control state from a definite path ($|\mathbf{0}\rangle_c$) into an equal superposition ($\frac{1}{\sqrt{2}}(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c)$), preparing the system to traverse both evolutionary pathways simultaneously.

Act II: Differential Evolution ($\mathbf{U}_{\mathrm{ctrl}}$) This is the core of the experiment, analogous to the two distinct arms of the interferometer. The system evolves under $\mathbf{U}_{\mathrm{ctrl}}$, which applies the evolution $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ to the $|\mathbf{0}\rangle_c$ component and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ to the $|\mathbf{1}\rangle_c$ component. This step imprints the differing dynamics of the two histories onto the state, creating a complex entanglement between the control system and the registers.

Act III: Path Recombination (Second H_c) The final Hadamard gate acts as the *second beam splitter*. It interferes the two paths by transforming the path information (held in the superposition basis) back into the computational basis ($\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$).

Revealing Interference Through Measurement This final transformation is what makes the quantum interference directly observable. A direct calculation shows that the final state of the system is:

$$\frac{1}{2}\left[|\mathbf{0}\rangle_c \otimes (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})|\Psi_{\mathrm{RR}}\rangle\right]$$

The interpretation of this result is remarkably direct:

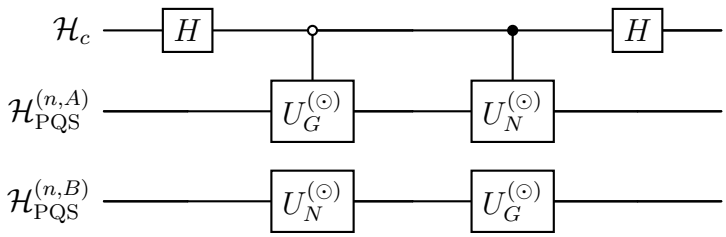
- The component of the final state associated with $|\mathbf{0}\rangle_c$ is proportional to the *sum* of the two path evolutions. Its amplitude represents their *constructive interference*.
- The component associated with $|\mathbf{1}\rangle_c$ is proportional to the *difference* between the path evolutions. Its amplitude represents their *destructive interference*.

A measurement of the control qubit in the computational basis now reveals a holistic property of the system that depends on all possible histories at once.

Conceptual Significance: From Branching to Interferometric Emergence This operator realizes a profound shift from a simple branching of histories (as with $\mathbf{U}_{\text{ctrl}}$) to a mechanism for *interferometric emergence*. The foundational principle of duality—the existence of two distinct but related parasymmetric evolutions—is no longer just a premise but becomes a measurable quantity.

The interference pattern, observable in the final probabilities of measuring $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$, is a direct probe into the relational similarity of the two dynamical histories. The operator $\mathbf{U}_{\text{Had}}$ thus provides the means for a quantum mechanical exploration of superposed causal pathways, making interference the primary tool for understanding how a single reality can emerge from a superposition of possibilities.

Definition 2.120 (Direct realization of $\mathbf{U}_{\text{Had}} = (H_c \otimes I)\,\mathbf{U}_{\text{ctrl}}\,(H_c \otimes I)$)**.** Using the controlled-path form of $\mathbf{U}_{\text{ctrl}}$ from eq. (2.75) with paths of eqs. (2.69) and (2.70), the Hadamard–conjugated operator of eq. (2.78) is:

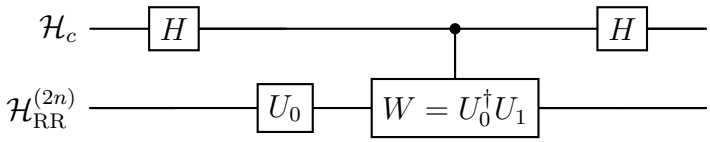


The open–control column applies $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ on branch $|\mathbf{0}\rangle_c$; the closed–control column applies $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ on branch $|\mathbf{1}\rangle_c$. The outer Hadamards implement the preparation and recombination in the control X basis, as in eq. (2.78).

Definition 2.121 (Canonical synthesis: baseline path plus controlled correction)**.** Let $U_0 := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $U_1 := \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$, and define $W := U_0^\dagger U_1$ (cf. eqs. (2.69) and (2.70)). Using the block form in eq. (2.75) and eq. (2.78),

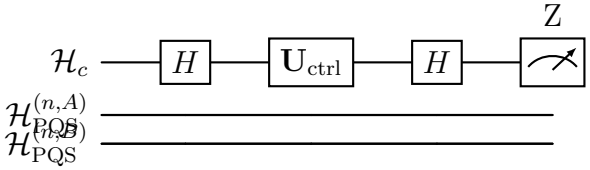
$$\begin{aligned}\mathbf{U}_{\text{Had}} &= (H_c \otimes I)\Big[\,|\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes U_0 + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes U_1\,\Big](H_c \otimes I) \\ &= (H_c \otimes I)\Big[\,\mathbb{I}_c \otimes U_0\,\Big]\Big[\,|1\rangle\langle 1|_c \otimes W + |0\rangle\langle 0|_c \otimes \mathbb{I}\,\Big](H_c \otimes I).\end{aligned}$$

A depth–efficient circuit therefore is:



Here U_0 acts unconditionally on the dual-register factor, and the single controlled-W column enacts the alternative path on the $|\mathbf{1}\rangle_c$ branch; the surrounding H gates realize preparation/recombination as in eq. (2.78).

Definition 2.122 (Interference readout on the control (optional))**.** To convert path interference into control-basis statistics, append a Z-measurement on the control after Definition 2.120 or Definition 2.121:



The measurement outcomes on the control encode the interference between $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ prepared and recombined by the Hadamards, as prescribed by eq. (2.78).

Deconstruction of the $\mathbf{U}_{\mathbf{Had}}$ Operator Circuit

Structural Stage	Mathematical Realization	Function / Role
Initial State	$\|\mathbf{0}\rangle_c \otimes \|\Psi_{\mathrm{RR}}\rangle$	Defines the starting point of the interferometric process with the control system in a definite basis state.
Act I: Path Creation	$H_c \otimes I_{\mathrm{RR}}^{(2n)}$	Acts as the first "beam splitter." Prepares the control qubit in a superposition, enabling simultaneous traversal of both dynamical branches.
Act II: Path Evolution	$\mathbf{U}_{\mathrm{ctrl}}$	Applies branch-dependent dynamics: $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ to the $\|\mathbf{0}\rangle_c$ component and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ to the $\|\mathbf{1}\rangle_c$ component.
Act III: Path Recombination	$H_c \otimes I_{\mathrm{RR}}^{(2n)}$	Acts as the second "beam splitter." Recombines the branches and translates their relative dynamics into measurable interference.
Composite Operator	$\mathbf{U}_{\mathrm{Had}}$	Represents the full interferometer circuit: a holosymmetric evolution that coherently superposes and recombines quantum histories.
Interference Readout	Measure in the $\{\|\mathbf{0}\rangle_c, \|\mathbf{1}\rangle_c\}$ basis	Reveals the interference pattern. The outcome amplitudes reflect the sum and difference of the path-dependent evolutions.

Table 2.2: Deconstruction of the $\mathbf{U}_{\mathrm{Had}}$ Operator Circuit

2.4 The Interferometer Model of Holosymmetric Evolution

The Interferometer Model implements a holosymmetric recursive transformation of modal evolution based on the logic:

Prepare Superposition → Evolve Conditional Paths → Recombine and Measure

Let the initial holosymmetric state be given by:

$$|\Psi_{\text{init}}\rangle := |\mathbf{0}\rangle_c \otimes |\Psi\rangle_{\text{RR}},$$

where $|\Psi\rangle_{\text{RR}} \in \mathcal{H}_{\text{RR}}^{(2n)}$ is an arbitrary normalized PQS configuration.

The model is built from the following elementary components:

(i) Preparation Gate $\mathbf{U}_{\text{prep}} \in \mathcal{U}(\mathcal{H}_c \otimes \mathcal{H}_{\text{RR}})$ The **preparation gate** is a unitary transformation that acts only on the control register $\mathcal{H}_c \cong \mathbb{C}^2$, and is tensored trivially with the identity on the register system $\mathcal{H}_{\text{RR}}^{(2n)}$. It is defined by:

$$\mathbf{U}_{\text{prep}} := (U_c^{\text{prep}} \otimes I_{\text{RR}}),$$

where:

$$U_c^{\text{prep}} \in \text{SU}(2) \quad \text{and} \quad I_{\text{RR}} := \mathbb{I}_{2^{4n}}.$$

In matrix form, any $U_c^{\text{prep}} \in \text{SU}(2)$ may be expressed as:

$$U_c^{\text{prep}} = \begin{pmatrix} \alpha & -\beta^* \\ \beta & \alpha^* \end{pmatrix}, \qquad \text{with} \quad |\alpha|^2 + |\beta|^2 = 1.$$

The action of $\mathbf{U}_{\text{prep}}$ on the initial state produces:

$$\mathbf{U}_{\text{prep}} \left(|\mathbf{0}\rangle_c \otimes |\Psi\rangle_{\text{RR}} \right) = \left(\alpha \, |\mathbf{0}\rangle_c + \beta \, |\mathbf{1}\rangle_c \right) \otimes |\Psi\rangle_{\text{RR}}.$$

This generalizes the **Hadamard preparation**, which corresponds to the specific choice:

$$U_c^{\text{prep}} = H := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \quad \Rightarrow \quad \mathbf{U}_{\text{prep}}^{(\text{Had})} = (H \otimes I_{\text{RR}}).$$

In this case:

$$\mathbf{U}_{\text{prep}}^{(\text{Had})} \left(|\mathbf{0}\rangle_c \otimes |\Psi\rangle_{\text{RR}} \right) = \frac{1}{\sqrt{2}} \left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c \right) \otimes |\Psi\rangle_{\text{RR}}.$$

More generally, by selecting arbitrary $\alpha, \beta \in \mathbb{C}$ subject to unitarity, the gate $\mathbf{U}_{\text{prep}}$ allows initialization of the control qubit into any point on the Bloch sphere, enabling fine-grained control over the interference landscape.

(ii) Controlled Evolution Operator $\mathbf{U}_{\text{ctrl}}$ Defined as:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

which branches the system into two parasymmetric dynamical pathways based on the control register state.

(iii) Readout Gate $\mathbf{U}_{\text{read}} \in \mathcal{U}(\mathcal{H}_c \otimes \mathcal{H}_{\text{RR}})$ The **readout gate** defines the basis in which interference will be observed. It acts only on the control register and is tensored with the identity on the register space:

$$\mathbf{U}_{\text{read}} := (U_c^{\text{read}} \otimes I_{\text{RR}}),$$

with:

$$U_c^{\text{read}} = \begin{pmatrix} \gamma & -\delta^* \\ \delta & \gamma^* \end{pmatrix}, \qquad |\gamma|^2 + |\delta|^2 = 1.$$

Applied to the general superposition:

$$|\chi\rangle_c \otimes |\Phi\rangle_{\text{RR}} = (a\,|\mathbf{0}\rangle_c + b\,|\mathbf{1}\rangle_c) \otimes |\Phi\rangle_{\text{RR}},$$

the output is:

$$(\gamma a - \delta^* b)\,|\mathbf{0}\rangle_c \otimes |\Phi\rangle_{\text{RR}} + (\delta a + \gamma^* b)\,|\mathbf{1}\rangle_c \otimes |\Phi\rangle_{\text{RR}}.$$

Choosing:

$$U_c^{\text{read}} = H := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad \Rightarrow \quad \mathbf{U}_{\text{read}}^{(\text{Had})} = (H \otimes I_{\text{RR}})$$

projects the output into the symmetric/antisymmetric basis.

Geometric Interpretation: The readout gate selects a measurement axis on the Bloch sphere, thereby choosing which interference modes become observable.

Operational Role: As the final gate before measurement, $\mathbf{U}_{\text{read}}$ determines which quantum interference patterns are revealed in the control register.

2.4.1 (1) Symmetric Interferometer Model

Definition 2.123 (Symmetric Interferometer Holosymmetric Operator)**.** Let $H_c \in \text{SU}(2)$ denote the Hadamard gate acting on the control register $\mathcal{H}_c \cong \mathbb{C}^2$, and let $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \in \mathcal{U}(\mathcal{H}_{\text{RR}}^{(2n)})$ be the evolution operators for the two complementary parasymmetric dynamical assignments on the PQS registers.

Then the *Symmetric Holosymmetric Interferometric Operator* is defined as:

$$\mathbf{U}_{\text{holo}}^{(\text{sym})} := \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}},$$

where:

- The Hadamard gate on the composite system is:

$$\mathbf{U}_{\text{Had}} := H_c \otimes I_{\text{RR}}, \quad \text{with} \quad H_c := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix},$$

- The Controlled Holosymmetric Operator is:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}.$$

Action on the initial state:
Let the initial state of the total system be:

$$|\Psi_{\text{init}}\rangle := |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle,$$

where $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ is an arbitrary normalized joint PQS state.
Then:

1. **First Hadamard:**

$$\mathbf{U}_{\text{Had}} |\Psi_{\text{init}}\rangle = \frac{1}{\sqrt{2}} (|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \otimes |\Psi_{\text{RR}}\rangle.$$

2. **Controlled evolution:**

$$\mathbf{U}_{\text{ctrl}} \circ \mathbf{U}_{\text{Had}} |\Psi_{\text{init}}\rangle = \frac{1}{\sqrt{2}} \left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} |\Psi_{\text{RR}}\rangle \right).$$

3. **Second Hadamard:**

$$\mathbf{U}_{\text{holo}}^{(\text{sym})} |\Psi_{\text{init}}\rangle = \frac{1}{2} \left[|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_+ |\Psi_{\text{RR}}\rangle \right) + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_- |\Psi_{\text{RR}}\rangle \right) \right],$$

where:

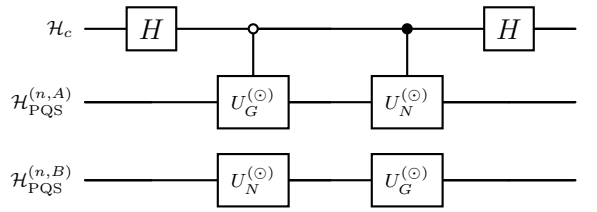
$$\hat{\mathbf{U}}_+ := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}, \quad \hat{\mathbf{U}}_- := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}.$$

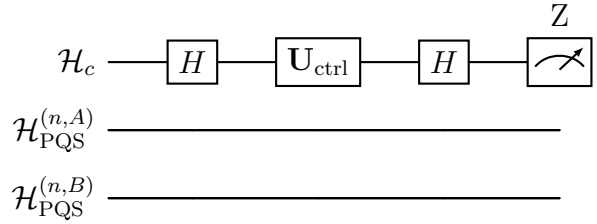
Interpretation. The operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ coherently prepares the control system in a symmetric superposition, evolves the dual PQS register along two distinct conditional paths, and recombines these paths to yield a final state in which the control register encodes the modal interference structure between the two pathways.

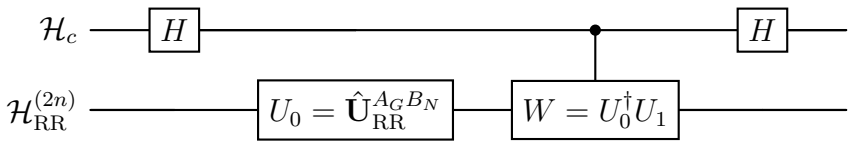
Measuring the control qubit in the computational basis reveals whether the interference is constructive ($|\mathbf{0}\rangle_c$) or destructive ($|\mathbf{1}\rangle_c$), corresponding to the interference norms $\|\hat{\mathbf{U}}_+ |\Psi_{\text{RR}}\rangle\|^2$ and $\|\hat{\mathbf{U}}_- |\Psi_{\text{RR}}\rangle\|^2$ respectively.

Symmetric interferometer.

$$\mathbf{U}_{\text{holo}}^{(\text{sym})} = \mathbf{U}_{\text{Had}} \, \mathbf{U}_{\text{ctrl}} \, \mathbf{U}_{\text{Had}}$$







2.4.2 (2) Asymmetric Interferometer Model

Definition 2.124 (Asymmetric Interferometer Holosymmetric Operator)**.** Let $U_c^{\mathrm{prep}}, U_c^{\mathrm{read}} \in \mathrm{SU}(2)$ be arbitrary unitary operators on the control register $\mathcal{H}_c \cong \mathbb{C}^2$. Then the *asymmetric holosymmetric interferometric operator* is defined by:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{asym})} := \mathbf{U}_{\mathrm{read}} \cdot \mathbf{U}_{\mathrm{ctrl}} \cdot \mathbf{U}_{\mathrm{prep}},$$

where:

- **Preparation Gate:**

$$\mathbf{U}_{\mathrm{prep}} := U_c^{\mathrm{prep}} \otimes I_{\mathrm{RR}}, \quad \text{with} \quad U_c^{\mathrm{prep}} = \begin{pmatrix} \alpha & -\beta^* \\ \beta & \alpha^* \end{pmatrix}, \quad |\alpha|^2 + |\beta|^2 = 1.$$

- **Controlled Evolution:**

$$\mathbf{U}_{\mathrm{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.$$

- **Readout Gate:**

$$\mathbf{U}_{\mathrm{read}} := U_c^{\mathrm{read}} \otimes I_{\mathrm{RR}}, \quad \text{with} \quad U_c^{\mathrm{read}} = \begin{pmatrix} \gamma & -\delta^* \\ \delta & \gamma^* \end{pmatrix}, \quad |\gamma|^2 + |\delta|^2 = 1.$$

State Evolution:
Let the initial state be:

$$|\Psi_{\mathrm{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle.$$

Then:

1. **Preparation:**
$$\mathbf{U}_{\mathrm{prep}} |\Psi_{\mathrm{init}}\rangle = (\alpha |\mathbf{0}\rangle_c + \beta |\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle.$$
2. **Controlled Evolution:**
$$\mathbf{U}_{\mathrm{ctrl}} \circ \mathbf{U}_{\mathrm{prep}} |\Psi_{\mathrm{init}}\rangle = \alpha |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} |\Psi_{\mathrm{RR}}\rangle + \beta |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} |\Psi_{\mathrm{RR}}\rangle.$$
3. **Readout:**
$$\begin{aligned} \mathbf{U}_{\mathrm{read}} \circ \mathbf{U}_{\mathrm{ctrl}} \circ \mathbf{U}_{\mathrm{prep}} |\Psi_{\mathrm{init}}\rangle = &\left[\gamma\alpha |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} |\Psi_{\mathrm{RR}}\rangle - \delta^*\beta |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} |\Psi_{\mathrm{RR}}\rangle\right] \\ &+ \left[\delta\alpha |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} |\Psi_{\mathrm{RR}}\rangle + \gamma^*\beta |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} |\Psi_{\mathrm{RR}}\rangle\right]. \end{aligned}$$

Interpretation. This construction generalizes the symmetric interferometer by allowing arbitrary superposition preparation and measurement bases. The interference structure no longer resolves simply into symmetric vs antisymmetric combinations, but rather into projective amplitudes defined by (α, β) and (γ, δ)—the control qubit's "in" and "out" basis states.

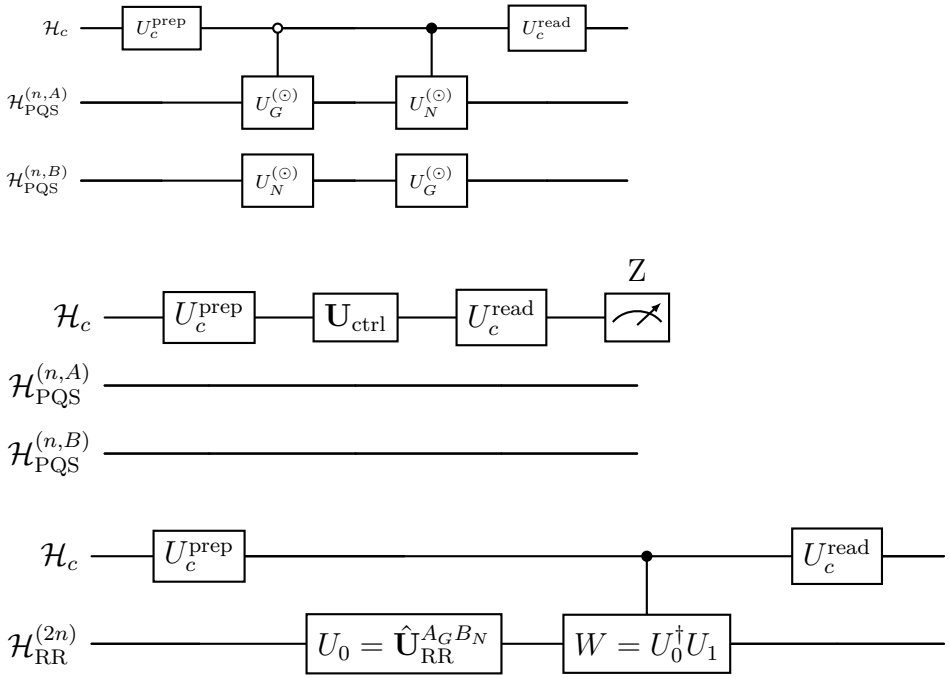
Hence, this operator:

- Encodes an asymmetrical duality of dialectical histories.
- Allows experimental probing of off-diagonal modal interference.
- Supports tunable observables via the preparation/readout gates U_c^{prep}, U_c^{read}.

This form is ideal for studying holosymmetric curvature, selective path filtering, or for embedding recursive gate dynamics in general holosymmetric protocols.

Asymmetric interferometer.

$$\mathbf{U}_{\text{holo}}^{(\text{asym})} = \mathbf{U}_{\text{read}}\, \mathbf{U}_{\text{ctrl}}\, \mathbf{U}_{\text{prep}}$$



Symmetric interferometer (the "fair splitter" version). Picture a fair, 50/50 beam splitter that sends a single *control light* down two routes at once. Along Route A, Register A performs the coordinated, entangling choreography while Register B follows a simple, independent routine; along Route B, those roles are swapped. After both routes run in parallel, a second fair splitter recombines them. If the two routes produced matching stories, their waves align and add (a bright outcome); if they differ, the waves cancel (a dark outcome). The brightness pattern on the control light is therefore a direct readout of how different those two dynamical stories are. "Symmetric" means both the initial split and the final recombination are perfectly balanced, making the device maximally sensitive to differences between the routes.

Asymmetric interferometer (the "tunable splitter" version). Here the fair splitters are replaced with adjustable ones. The first splitter can send more weight to one route than the other and can also dial in a relative phase; the final splitter can choose a different recombination angle and readout basis. These adjustments act like knobs that scan and amplify particular aspects of the interference between the two stories—sometimes emphasizing agreement, sometimes teasing out subtle mismatches that the symmetric version might gloss over. In short, it is the same two-route test, but with tunable "in" and "out" settings that bias the comparison, control sensitivity, and probe different facets of "who coordinates" and "who does not."

What both achieve. Both versions run two alternative, system-wide histories in parallel and then let those histories interfere. The symmetric model provides the clean, balanced baseline—maximum contrast with minimal tuning—while the asymmetric model is the lab-ready variant with extra control, able to favor a route, rotate the readout, and reveal finer structure in the differences between the two dynamical assignments.

From logic and algebra to quantum circuits. The compiled circuits are not only interesting—they are concrete, operational realizations of the *Fourfold Dialectic Algebra* of Chapter 1 on the $(0,1)$ modal sector. They implement, in hardware terms, the corner states $\mathsf{Th}, \mathsf{AntiTh}, \mathsf{SynTh}, \mathsf{HoloTh}$, the associated effects $(P_T, P_A, P_{\text{para}}, E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})})$, and the dualization maps $(\mathbf{D}_{\mathcal{C}}, \Delta_{\mathcal{C}})$ on $\mathcal{A}_x^{(4)}$.

Corners $\mathsf{Th}/\mathsf{AntiTh}$ as a logical qubit. The ringed–ket basis $\{|\mathring{\mathbf{0}}\rangle, |\mathring{\mathbf{1}}\rangle\}$ from Definition 2.1 realizes the $\mathsf{Th}/\mathsf{AntiTh}$ corners of Chapter 1; the effects $P_T := |e_1\rangle\langle e_1|$ and $P_A := |e_2\rangle\langle e_2|$ are their Born tests on $\mathcal{A}_x^{(4)}$. The local involutive duality $D^{(\mathfrak{B}_x)}$ and its global lift $\hat{D}_{\text{PQS}}^{(n)}$ (Definitions 2.7 and 2.12) implement the categorical dualization $\mathbf{D}_{\mathcal{C}}$ and its configuration–wide action $\Delta_{\mathcal{C}}$ by swapping $\mathsf{Th} \leftrightarrow \mathsf{AntiTh}$ (Pauli–X on the logical qubit).

Synthesis SynTh as parasymmetry. The parasymmetric projector $P_{\text{para}}^{(x)} = |+\rangle\langle +|$ and its orthogonal complement $P_{\text{antipara}}^{(x)} = |-\rangle\langle -|$ (eq. (2.57)) resolve the $\mathsf{Th}/\mathsf{AntiTh}$ line into *synthesis* vs. *dissonance*. Their Naimark–flag circuits (local, pairwise, global) are the operational versions of the SynTh effect in Chapter 1, while the invariance criterion $UP_{\text{para}}^{(x_1\ldots x_n)}U^\dagger = P_{\text{para}}^{(x_1\ldots x_n)}$ (eq. (2.60)) characterizes the *parasymmetry–preserving* automorphisms of the $(0,1)$ corner-subalgebra of $\mathcal{A}_x^{(4)}$.

Holosymmetry HoloTh as interferometric composition. The controlled-path and Hadamard-conjugated operators $\mathbf{U}_{\text{ctrl}}$ and $\mathbf{U}_{\text{Had}}$ (Definitions 2.114 and 2.119) realize the holosymmetric corner HoloTh as *interference of dynamical assignments*: prepare, branch, recombine. In algebraic terms, the symmetric interferometer produces the sum/difference channels

$$\hat{\mathbf{U}}_{\pm} = \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} \pm \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

so that measuring the control implements the holosymmetric effects $E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ which compare relational histories $(\mathbf{a}, \mathbf{b})$ by constructive/destructive interference. The asymmetric interfer-

ometer generalizes this comparison to arbitrary SU(2) "in/out'' axes on the control, exposing off–diagonal holosymmetric structure.

Generators and flows in $\mathcal{A}_x^{(4)}$. The unitary families $U_N^{(\odot)}, U_G^{(\hat{\sigma})}, U_G^{(\lambda)}, U_G^{(\odot)}$ we built (decoupled, exchange–coupled, composite, unified) are exponentials of Hermitian combinations of the Chapter 1 effects, i.e. elements generated by $\hat{\mathcal{F}}_\alpha$ inside the automorphism group of the Fourfold algebra. Their commutation with P_{para} (when present) certifies closure on the SynTh sector, while duality gates realize $\mathbf{D}_\mathcal{C}$ as an involution on that sector.

Conclusion. Taken together, the circuits instantiate the Chapter 1 logic *as dynamics*: Th/AntiTh as a logical basis, SynTh as coherent superposition and its projector, HoloTh as interferometric comparison of whole relational evolutions, and $\mathbf{D}_\mathcal{C}, \Delta_\mathcal{C}$ as involutive symmetries at local and global scale. In short, the quantum circuits are the operational semantics of the tetralemmatic algebra $\mathcal{A}_x^{(4)}$.

Chapter 3

The Double-Slit Experiments

3.1 The Double-Slit Experiment for The Interferometer Model

3.1.1 Experiment for the Symmetric Interferometer Model

The fundamental quantum principle of interference, exemplified by the iconic double-slit experiment, is radically generalized within the holosymmetric framework. Here, the *slits* are not spatial apertures but entire, register-wide unitary evolutions, and the *interference pattern* is encoded not in particle distributions but in entangled amplitudes within a control qubit. This construction is made possible by the *Controlled Holosymmetric Operator* $\mathbf{U}_{\text{ctrl}}$ (Definition 2.114), which implements a superposition of two structurally distinct dynamical paths across dual quantum registers.

Mapping the Components of the Analogy We identify the components of this holosymmetric experiment with their canonical quantum analogues:

- **The Quantum System:** The dual-register quantum state $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$, composed of two disjoint arrays of n Primordial Quantum Singularities each (eq. (2.61)). This system plays the role of the particle traversing the interferometer.
- **The Two Slits:** The two distinct, globally unitary, register-wide dynamical paths:
  - $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} := U_G^{(A)} \cdot U_N^{(B)}$, where Register A undergoes globally coupled parasymmetric evolution and Register B evolves independently (eq. (2.69));
  - $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} := U_N^{(A)} \cdot U_G^{(B)}$, where the roles of coupling and decoupling are reversed (eq. (2.70)).

  These operators constitute mutually exclusive but physically complete dynamical branches — the quantum analogues of the slits through which the system may evolve.
- **The Detector Screen:** The control system $\mathcal{H}_c = \text{span}\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$, which registers the interference between the two holosymmetric paths. Measurement of the control qubit in a rotated basis reveals constructive or destructive interference, depending on the relative amplitudes and phases induced by the path operators.

The Three Experimental Acts of the Symmetric Interferometer The experimental procedure for the symmetric model can be elegantly framed as a three-act quantum-dynamical process.

Act I: Path Creation (Preparation) The experiment begins with the system in a definite initial state, with the control qubit aligned to a single basis vector, for instance $|\mathbf{0}\rangle_c$. The first act is to create a coherent superposition of evolutionary paths. This is achieved by applying the Hadamard preparation gate, $\mathbf{U}_{\text{prep}} = \mathbf{U}_{\text{Had}}$, which acts as the first "beam splitter."

- **Initial State:** $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$
- **Action:** Apply $\mathbf{U}_{\text{Had}}$
- **Prepared State:**

$$|\Psi_{\text{prep}}\rangle = \mathbf{U}_{\text{Had}} |\Psi_{\text{init}}\rangle = \left(\frac{1}{\sqrt{2}} (|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c) \right) \otimes |\Psi_{\text{RR}}\rangle$$

The system is now prepared to traverse both "slits"—the two distinct evolutionary pathways—simultaneously.

Act II: Differential Evolution (Branching) In the second act, the controlled unitary operator $\mathbf{U}_{\text{ctrl}}$ is applied. Each branch of the superposition now evolves according to its corresponding dynamical law, becoming entangled with the state of the registers.

- **State from Act I:** $|\Psi_{\text{prep}}\rangle$
- **Action:** Apply $\mathbf{U}_{\text{ctrl}}$
- **Entangled State:**

$$|\Psi_{\text{entangled}}\rangle = \mathbf{U}_{\text{ctrl}} |\Psi_{\text{prep}}\rangle = \frac{1}{\sqrt{2}} \left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} |\Psi_{\text{RR}}\rangle \right)$$

At the conclusion of this act, the system exists in a profound superposition, with the control qubit encoding which evolutionary history has been applied to which branch.

Act III: Recombination and Measurement The final act recombines the two paths to reveal their interference. The second Hadamard gate, $\mathbf{U}_{\text{read}} = \mathbf{U}_{\text{Had}}$, is applied, acting as the final "beam splitter" before the detector.

- **State from Act II:** $|\Psi_{\text{entangled}}\rangle$
- **Action:** Apply $\mathbf{U}_{\text{Had}}$
- **Final State:**

$$\begin{aligned} |\Psi_{\text{final}}\rangle &= (\mathbf{U}_{\text{Had}} \otimes \mathbb{I}) |\Psi_{\text{entangled}}\rangle \\ &= \frac{1}{2} \left(|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle \right) \end{aligned}$$

This final state is then measured. The probability of finding the control qubit in each basis state is determined by the constructive or destructive interference of the two paths:

$$\Pr[\mathbf{0}] = \frac{1}{4}\left\|\left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle\right\|^2,$$
$$\Pr[\mathbf{1}] = \frac{1}{4}\left\|\left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right)|\Psi_{\mathrm{RR}}\rangle\right\|^2.$$

This three-act structure provides a clear, rigorous, and physically intuitive framework for understanding the holosymmetric interferometer in the symmetric model.

Interpretation: Interference in the Symmetric Model This construction elevates the classical notion of path interference to a higher categorical level. In the symmetric model, the use of identical Hadamard gates for both preparation and recombination establishes a perfectly balanced apparatus. Consequently, the resulting interference pattern becomes a direct measure of the *functional symmetry* between the two evolutionary paths, $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$.

What interferes here are not trajectories through spacetime, but entire unitary evolutions. The final probabilities, p_0 and p_1, are determined by the quantum overlap integral:

$$\mathcal{O} = \langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle$$

Specifically, the probabilities depend directly on the *real part* of this complex-valued amplitude, $\mathrm{Re}(\mathcal{O})$, which cleanly quantifies the degree of constructive or destructive interference between the two symmetrically prepared and recombined holosymmetric evolutions.

The Recursive Structure Crucially, this holosymmetric double-slit architecture is *recursive*. The states $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle$ are not static outputs; they themselves encode coupled parasymmetric dynamics across the n-PQS registers—dynamics that can be recursively decomposed into further layers of parasymmetric superpositions and entanglement. Thus, the holosymmetric interference pattern contains within it multiple strata of modal interference, reflecting a fractal-like coherence structure that generalizes Feynman's sum-over-paths into a sum-over-histories-of-evolutions.

Remark 3.1 (Symmetric Interferometer Visibility as a Dialectic Measurement)**.** In the specific case of the symmetric interferometer, the probability distribution on the control qubit acts as a particularly clear physical *visibility functional*. It is a quantum measurement device not for position or momentum, but for operator-theoretic duality.

Maximal constructive interference ($p_1 = 0$) occurs if and only if the two evolutionary paths produce an identical final state from the given initial state:

$$\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle$$

This signifies a perfect *functional symmetry* between the two dynamics with respect to the input state $|\Psi_{\mathrm{RR}}\rangle$.

Conversely, maximal destructive interference ($p_0 = 0$) occurs when the two paths yield perfectly anti-correlated final states:

$$\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle = -\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}|\Psi_{\mathrm{RR}}\rangle$$

This condition reveals a state of perfect *modal complementarity*. These clean interpretations are a direct result of the symmetric preparation and readout stages.

Recursive Interference and the Structure of the Symmetric Interferometer

The Symmetric Operator as a Complete Interferometer To probe the recursive nature of quantum interference, we analyze the full structure of the *Symmetric Interferometer Holosymmetric Operator*, $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$. This operator's very structure encapsulates a complete interferometric circuit (*Prepare* $\rightarrow$ *Evolve* $\rightarrow$ *Recombine*) as a single, composite transformation on the state space. It is defined as:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})} := \mathbf{U}_{\mathrm{Had}} \cdot \mathbf{U}_{\mathrm{ctrl}} \cdot \mathbf{U}_{\mathrm{Had}}.$$

To understand its properties, we derive its matrix representation in the control basis $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$. Using the block matrix forms for $\mathbf{U}_{\mathrm{ctrl}}$ and $\mathbf{U}_{\mathrm{Had}}$, we find:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})} = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\begin{pmatrix} \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} & 0 \\ 0 & \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} \hat{\mathbf{U}}_+ & \hat{\mathbf{U}}_- \\ \hat{\mathbf{U}}_- & \hat{\mathbf{U}}_+ \end{pmatrix},$$

where

$$\hat{\mathbf{U}}_\pm := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \pm \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.$$

Action on a Simple Initial State Let us now apply this operator to the simple initial state $|\Psi_{\mathrm{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle$. A direct calculation yields:

$$|\Psi_{\mathrm{final}}\rangle = \mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}|\Psi_{\mathrm{init}}\rangle = \frac{1}{2}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right).$$

This leads to the measurement probabilities:

$$p_0 = \frac{1}{4}\left\|\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle\right\|^2, \qquad p_1 = \frac{1}{4}\left\|\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right\|^2.$$

This result is mathematically sound and reveals a crucial insight: applying the full interferometric circuit $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ to a simple basis state is operationally equivalent to preparing a superposition and measuring the interference once.

The True Nature of Second-Order Coherence The "recursive" or "second-order" nature of the model is not found in the outcome of this simple experiment. It is encoded within the *off-diagonal elements* of the matrix representation of $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ itself.

The term $\mathbf{F}_{01} = \frac{1}{2}\hat{\mathbf{U}}_-$ describes the amplitude for a system that *starts* in the $|\mathbf{1}\rangle_c$ branch to be *measured* in the $|\mathbf{0}\rangle_c$ branch after the full process. This "path-flipping" amplitude is a

direct measure of the interference between histories and reveals how the operator acts on general superpositions.

A true second-order experiment would involve probing this transformative structure directly—for instance, by preparing a more complex initial state, or by applying the operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ sequentially. The conceptual vision of "interference of interference" is thus a property of the full transformation, liberated from its most basic application.

Conceptual Reinterpretation: Second-Order Interference The recursive architecture of holosymmetry is not about a single measurement, but about the structure of the transformations themselves.

- **First-order interference** is the phenomenon of interfering two paths, quantified by the probabilities p_0 and p_1 derived above.
- **Second-order coherence** is encoded in the full operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$. This operator acts as a map on the Hilbert space of histories—it transforms an *input* interference pattern into an *output* interference pattern.

The framework thus allows us to ask not just "Which path was taken?" but the more profound question:

"What is the quantum relationship between different interference-resolved evolutions?"

The answer lies in the algebraic structure of $\mathbf{U}_{\text{holo}}^{(\text{sym})}$. It is the engine that drives the evolution of modal logic itself.

Remark 3.2 (Second-Order Interference as Recursive Holosymmetric Dialectic)**.** This second-order construction completes the dialectical architecture of holosymmetry. The interference terms $\hat{\mathbf{U}}_{\pm}$ represent opposing modal perspectives on path coherence, while their recursive combination within the operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ reflects a synthesis of interference modalities. The operator itself thus constitutes an operational probe of the internal logical structure governing the superposition of entire evolutionary frameworks.

3.1.2 Interference Expectation in the Symmetric Interferometer Model

Corollary 3.3 (Interference Expectation: Symmetric Interferometer)**.** *Let* $\mathbf{U}_{holo}^{(sym)}$ *denote the Symmetric Interferometer Holosymmetric Operator (Definition 2.123), acting on the holosymmetric Hilbert space* $\mathcal{H}_{\text{Holo}} := \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)}$*. Suppose the system is initialized in the product state:*

$$|\Psi_{\text{init}}\rangle := |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle,$$

where $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ *is a normalized state of the dual PQS registers, and* $|\mathbf{0}\rangle_c$ *is a basis state of the control system.*

Then the probability p_0 *of measuring the control system in the state* $|\mathbf{0}\rangle_c$ *after application of* $\mathbf{U}_{holo}^{(sym)}$ *is given by:*

$$\boxed{p_0 = \frac{1}{4}\left\|\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\right\|^2 = \frac{1}{4}\left\|\hat{\mathbf{U}}_{+}|\Psi_{\text{RR}}\rangle\right\|^2,} \tag{3.1}$$

where the constructive path operator is defined as:

$$\hat{\mathbf{U}}_{+} := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.$$

Interpretation. *The measurement outcome is governed by the constructive interference between the two distinct holosymmetric branches. The probability of measuring $|\mathbf{0}\rangle_c$ is directly proportional to the squared norm of the coherent sum of the state vectors produced by each evolutionary path. This is a first-order interference effect that provides a direct measure of the functional symmetry between the two dynamics as they act on the initial state.*

Proof of Corollary 3.3. Let the system be initialized in the product state:

$$|\Psi_{\mathrm{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle,$$

where $|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}$ is normalized. The full evolution is governed by the Symmetric Interferometer Holosymmetric Operator:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})} := \mathbf{U}_{\mathrm{Had}}\, \mathbf{U}_{\mathrm{ctrl}}\, \mathbf{U}_{\mathrm{Had}} \quad (\text{ Definition 2.123}).$$

We compute the final state by applying these operators sequentially.

Act I: Path Creation (First Hadamard Gate). The first Hadamard operator acts on the control qubit, creating a superposition of paths:

$$\begin{aligned} |\Psi_{\mathrm{prep}}\rangle &:= \mathbf{U}_{\mathrm{Had}} |\Psi_{\mathrm{init}}\rangle \\ &= \frac{1}{\sqrt{2}} \left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c \right) \otimes |\Psi_{\mathrm{RR}}\rangle. \end{aligned}$$

Act II: Differential Evolution (Controlled Operator). The controlled operator $\mathbf{U}_{\mathrm{ctrl}}$ applies the distinct evolutionary paths to each branch of the superposition, creating an entangled state:

$$\begin{aligned} |\Psi_{\mathrm{entangled}}\rangle &:= \mathbf{U}_{\mathrm{ctrl}} |\Psi_{\mathrm{prep}}\rangle \\ &= \frac{1}{\sqrt{2}} \left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} |\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} |\Psi_{\mathrm{RR}}\rangle \right). \end{aligned}$$

Act III: Path Recombination (Second Hadamard Gate). The final Hadamard gate acts on the control system, recombining the paths to produce interference:

$$\begin{aligned} |\Psi_{\mathrm{final}}\rangle &:= \mathbf{U}_{\mathrm{Had}} |\Psi_{\mathrm{entangled}}\rangle \\ &= \frac{1}{2} \Big[|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \\ &\quad + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \Big]. \end{aligned}$$

Using the definitions $\hat{\mathbf{U}}_+ := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ and $\hat{\mathbf{U}}_- := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, the final state is:

$$|\Psi_{\text{final}}\rangle = \frac{1}{2}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right).$$

To compute the probability of measuring the control register in state $|\mathbf{0}\rangle_c$, we take the squared norm of the corresponding amplitude in the final state:

$$p_0 = \|\langle \mathbf{0}|_c|\Psi_{\text{final}}\rangle\|^2 = \left\|\frac{1}{2}\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle\right\|^2 = \frac{1}{4}\left\|\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle\right\|^2.$$

This is precisely the expression given in Corollary Corollary 3.3. □

3.1.3 Complementary Interference Probability

Proof. We seek to derive the probability, p_1, of measuring the control qubit in the state $|\mathbf{1}\rangle_c$. This is the complementary outcome to the probability p_0 derived in the proof of Corollary Corollary 3.3.

We begin by recalling the correctly derived final state of the system after the action of the Symmetric Interferometer Holosymmetric Operator, $\mathbf{U}_{\text{holo}}^{(\text{sym})}$:

$$|\Psi_{\text{final}}\rangle = \frac{1}{2}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right).$$

To find the probability p_1, we project this final state onto the desired outcome $|\mathbf{1}\rangle_c$ and compute the squared norm of the resulting amplitude:

$$p_1 = \|\langle \mathbf{1}|_c|\Psi_{\text{final}}\rangle\|^2.$$

Performing the projection yields:

$$\langle \mathbf{1}|_c|\Psi_{\text{final}}\rangle = \frac{1}{2}\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle.$$

Taking the squared norm gives the final expression for the probability:

$$p_1 = \left\|\frac{1}{2}\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right\|^2 = \frac{1}{4}\left\|\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right\|^2.$$

Consistency via Unitarity. As a necessary check, the total probability must be conserved. Let us verify that $p_0 + p_1 = 1$.

$$\begin{aligned} p_0 + p_1 &= \frac{1}{4}\left(\left\|\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle\right\|^2 + \left\|\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right\|^2\right) \\ &= \frac{1}{4}\left(\langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_+^\dagger\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle + \langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_-^\dagger\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right). \end{aligned}$$

Using the definitions $\hat{\mathbf{U}}_\pm = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \pm \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, we expand the operators:

$$\begin{aligned} \hat{\mathbf{U}}_+^\dagger\hat{\mathbf{U}}_+ &= 2\mathbb{I} + (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N})^\dagger\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} + (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})^\dagger\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \\ \hat{\mathbf{U}}_-^\dagger\hat{\mathbf{U}}_- &= 2\mathbb{I} - (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N})^\dagger\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} - (\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})^\dagger\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \end{aligned}$$

Summing their expectation values, the cross-terms cancel, leaving:

$$p_0 + p_1 = \frac{1}{4}\left(\langle\Psi_{\mathrm{RR}}|4\mathbb{I}|\Psi_{\mathrm{RR}}\rangle\right) = \langle\Psi_{\mathrm{RR}}|\Psi_{\mathrm{RR}}\rangle = 1,$$

since $|\Psi_{\mathrm{RR}}\rangle$ is normalized. This confirms the internal consistency of the derivation and the completeness of the interference process. □

3.1.4 Visibility of Holosymmetric Interference: Symmetric Interferometer Model

Theorem 3.4 (Visibility of Holosymmetric Interference)**.** *Consider the symmetric holosymmetric interferometric configuration described in Corollary Corollary 3.3. Let the initial state be:*

$$|\Psi_{\mathrm{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle,$$

where $|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}$ is normalized. The system evolves under the Symmetric Interferometer Holosymmetric Operator $\mathbf{U}_{holo}^{(sym)}$, and the control qubit is measured in the computational basis with outcome probabilities p_0 and p_1.

The holosymmetric interference visibility *for this model is defined as the difference in outcome probabilities:*

$$\mathcal{V}_{\mathrm{sym}} := |p_0 - p_1|.$$

This visibility is given explicitly by the real part of the quantum overlap integral between the two evolved states:

$$\boxed{\mathcal{V}_{\mathrm{sym}} = \left|\mathrm{Re}\left(\langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right)\right|.} \tag{3.2}$$

Interpretation. *The visibility, $\mathcal{V}_{\mathrm{sym}}$, directly quantifies the degree of coherent interference between the two distinct evolutionary paths. It is a first-order measure of the relational similarity between the final states produced by the coupled ($A_G B_N$) and decoupled ($A_N B_G$) dynamics.*

A value of $\mathcal{V}_{\mathrm{sym}} = 1$ indicates maximal interference, where the two histories are perfectly aligned or anti-aligned in the Hilbert space. A value of $\mathcal{V}_{\mathrm{sym}} = 0$ indicates that the two final states are orthogonal, resulting in no interference pattern on the control qubit. The visibility thus serves as a direct, physical measure of the quantum coherence between two distinct universal histories.

Proof. The proof follows directly from the corrected probability expressions derived previously.

$$p_0 = \frac{1}{4}\left\|\hat{\mathbf{U}}_+|\Psi_{\mathrm{RR}}\rangle\right\|^2 = \frac{1}{4}\left(2 + 2\mathrm{Re}\langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right)$$
$$p_1 = \frac{1}{4}\left\|\hat{\mathbf{U}}_-|\Psi_{\mathrm{RR}}\rangle\right\|^2 = \frac{1}{4}\left(2 - 2\mathrm{Re}\langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right)$$

The visibility is therefore:

$$\begin{aligned}\mathcal{V}_{\mathrm{sym}} = |p_0 - p_1| &= \left|\frac{1}{2}\left(1 + \mathrm{Re}(\mathcal{O})\right) - \frac{1}{2}\left(1 - \mathrm{Re}(\mathcal{O})\right)\right| \\ &= |\mathrm{Re}(\mathcal{O})| \\ &= \left|\mathrm{Re}\left(\langle\Psi_{\mathrm{RR}}|\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}|\Psi_{\mathrm{RR}}\rangle\right)\right|,\end{aligned}$$

where $\mathcal{O}$ is the quantum overlap integral. This completes the proof. □

3.1.5 Experiment for the Asymmetric Interferometer Model

Mapping the Components of the Asymmetric Model In the Asymmetric Interferometer Model, the core components of the double-slit analogy are generalized to allow for more complex experimental control.

1. *The Quantum System:* This remains the dual-register quantum state $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$, which traverses the interferometric process.

2. *The Two Slits:* The "slits" are the same two distinct, globally unitary, register-wide dynamical paths as in the symmetric case:

   - Path 1: $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ (Coupled A / Decoupled B)
   - Path 2: $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ (Decoupled A / Coupled B)

3. *The Source of Asymmetry (The Gates):* The asymmetry is introduced by the preparation and readout stages, which are no longer fixed Hadamard gates but can be any SU(2) rotation.

   - *Asymmetric "Beam Splitter" ($\mathbf{U}_{prep}$)*: The preparation gate can create any arbitrary superposition $\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c$, effectively sending unequal or phase-shifted "amplitudes" through the two slits.
   - *Asymmetric "Analyzer" ($\mathbf{U}_{read}$)*: The readout gate projects the final interfered state onto an arbitrary basis on the control qubit's Bloch sphere before measurement. It acts as a tunable filter or polarizer for the interference pattern.

4. *The Detector Screen:* The control system $\mathcal{H}_c$ remains the detector, but the "fringes" (measurement probabilities) are now observed after being transformed by the readout gate $\mathbf{U}_{\text{read}}$, revealing different aspects of the quantum coherence between the two paths.

In essence, the Asymmetric Model uses the same two evolutionary "slits" but allows the experimenter to shine a "polarized" quantum state through them and observe the resulting interference pattern with a "polarized" detector.

The Three Acts of the Asymmetric Interferometer The Asymmetric Interferometer Model generalizes the symmetric case by allowing for arbitrary preparation and measurement bases, providing complete control over the interferometric process.

Act I: Asymmetric Preparation The experiment begins with the system in a simple basis state. The preparation gate $\mathbf{U}_{\text{prep}}$, an arbitrary $SU(2)$ rotation, then creates a potentially unequal or phase-shifted superposition.

- *Initial State:* $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$
- *Action:* Apply $\mathbf{U}_{\text{prep}} = U_c^{\text{prep}} \otimes I_{\text{RR}}$
- *Prepared State:*

$$|\Psi_{\text{prep}}\rangle = \mathbf{U}_{\text{prep}}|\Psi_{\text{init}}\rangle = (\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes |\Psi_{\text{RR}}\rangle$$

The system is now prepared to traverse both paths, but with potentially different initial amplitudes α and β.

Act II: Differential Evolution The controlled evolution proceeds exactly as in the symmetric case, applying the two distinct dynamical laws to the corresponding branches of the superposition.

- *State from Act I:* $|\Psi_{\text{prep}}\rangle$
- *Action:* Apply $\mathbf{U}_{\text{ctrl}}$
- *Entangled State:*

$$|\Psi_{\text{entangled}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{prep}}\rangle = \alpha|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle + \beta|\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}|\Psi_{\text{RR}}\rangle$$

Act III: Asymmetric Recombination and Measurement The final act recombines the two paths using the readout gate $\mathbf{U}_{\text{read}}$, which is also a general $SU(2)$ rotation. This gate projects the interfered state onto an arbitrary measurement basis before the final observation.

- *State from Act II:* $|\Psi_{\text{entangled}}\rangle$
- *Action:* Apply $\mathbf{U}_{\text{read}} = U_c^{\text{read}} \otimes I_{\text{RR}}$
- *Final State:*

$$\begin{aligned}|\Psi_{\text{final}}\rangle = (\mathbf{U}_{\text{read}} \otimes \mathbb{I})|\Psi_{\text{entangled}}\rangle =& |\mathbf{0}\rangle_c \otimes \left(\gamma\alpha\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^*\beta\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle \\ &+ |\mathbf{1}\rangle_c \otimes \left(\delta\alpha\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\end{aligned}$$

The measurement probabilities for observing $|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$ are the norm-squared of these final, complex amplitudes:

$$p_0 = \left\|\left(\gamma\alpha\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^*\beta\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\right\|^2$$

$$p_1 = \left\|\left(\delta\alpha\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\right\|^2$$

Interpretation: Probing Interference from Any Angle This generalized interferometric construction allows for a much richer analysis. The final interference pattern is no longer a simple measure of symmetry between the two paths, but a complex function of all eight parameters ($\alpha, \beta, \gamma, \delta$ and the path operators). By carefully choosing the preparation and readout gates, one can "rotate" the measurement basis on the Bloch sphere, allowing for a full quantum state tomography of the interference between universal histories.

Interpretation of the Asymmetric Model: Quantum Tomography of Histories The true power of the Asymmetric Interferometer Model lies in its ability to perform a full *tomography* of the quantum-relational structure between the two evolutionary pathways. Unlike the symmetric case, which provides a single, fixed view of the interference, the asymmetric model allows the "observer" to probe the interference from any desired angle on the control qubit's Bloch sphere.

The resulting measurement probabilities, p_0 and p_1, are no longer simple functions of the overlap between the two paths. They are complex functions of the preparation parameters (α, β), the readout parameters (γ, δ), and the two unitary evolutions $(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})$.

For instance, the probability of measuring the $|\mathbf{0}\rangle_c$ outcome is:

$$p_0 = \left\| \left(\gamma\alpha \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^* \beta \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \right\|^2$$

By systematically varying the preparation and readout gates, one can, in principle, extract both the magnitude and the phase of the quantum overlap integral $\mathcal{O} = \langle \Psi_{\mathrm{RR}} | \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G \dagger} \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} | \Psi_{\mathrm{RR}} \rangle$. This allows for a complete characterization of the quantum relationship between the two universal histories.

Remark 3.5 (Asymmetric Interferometer as a Tomographic Tool)**.** The Asymmetric Interferometer functions as a device for performing *quantum process tomography* on the interference of universal histories. It does detect the presence of interference and it provides the experimental control needed to fully map out the complex amplitude (both magnitude and phase) that quantifies the relational coherence between two distinct dynamical laws. This elevates the model from a simple comparative device to a complete diagnostic tool for probing the deep structure of holosymmetric evolution.

Interference and Visibility: Asymmetric Interferometer Model

The Asymmetric Interference Process The Asymmetric Interferometer Model provides a powerful generalization of the symmetric case by allowing the experimenter to probe the interference between the two evolutionary paths, $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, from any "angle" on the control qubit's Bloch sphere.

The process unfolds as we previously derived: an arbitrary preparation $\mathbf{U}_{\mathrm{prep}}$ creates an initial superposition $(\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes |\Psi_{\mathrm{RR}}\rangle$; this state evolves via $\mathbf{U}_{\mathrm{ctrl}}$; and finally, an arbitrary readout $\mathbf{U}_{\mathrm{read}}$ is applied before measurement.

The final state of the system is:

$$\begin{aligned} |\Psi_{\mathrm{final}}\rangle = & |\mathbf{0}\rangle_c \otimes \left(\gamma\alpha \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^* \beta \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \\ & + |\mathbf{1}\rangle_c \otimes \left(\delta\alpha \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \gamma^* \beta \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \end{aligned}$$

Asymmetric Visibility and Quantum Tomography The measurement probabilities p_0 and p_1 are the squared norms of the amplitudes corresponding to the $|\mathbf{0}\rangle_c$ and $|\mathbf{1}\rangle_c$ branches. For instance:

$$p_0 = \left\| \left(\gamma\alpha \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^* \beta \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \right\|^2$$

Expanding this expression reveals its rich structure:

$$p_0 = |\gamma\alpha|^2 \|\hat{\mathbf{U}}_A \Psi\|^2 + |\delta\beta|^2 \|\hat{\mathbf{U}}_B \Psi\|^2 - 2\mathrm{Re}\left(\gamma\alpha\beta^* \delta \langle \Psi | \hat{\mathbf{U}}_B^\dagger \hat{\mathbf{U}}_A | \Psi \rangle \right)$$

(where $\hat{\mathbf{U}}_A$ is shorthand for $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$. This operator describes the evolution where *Register A* undergoes globally coupled dynamics ($U_G^{(A)}$) while *Register B* undergoes decoupled dynamics ($U_N^{(B)}$). And, $\hat{\mathbf{U}}_B$ is shorthand for $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$. This operator describes the complementary evolution where *Register A* is decoupled ($U_N^{(A)}$) and *Register B* is globally coupled ($U_G^{(B)}$)).

Unlike the symmetric case where visibility only depends on the real part of the overlap integral $\mathcal{O} = \langle \Psi | \hat{\mathbf{U}}_B^\dagger \hat{\mathbf{U}}_A | \Psi \rangle$, the asymmetric model's outcome depends on the full complex value of $\mathcal{O}$ and its interplay with the four complex parameters $\alpha, \beta, \gamma, \delta$.

Remark 3.6 (Asymmetric Interferometer as a Tomographic Tool)**.** The Asymmetric Interferometer functions as a device for performing *quantum process tomography* on the interference of universal histories. By systematically varying the preparation and readout gates (i.e., choosing different values for $\alpha, \beta, \gamma, \delta$), an experimenter can, in principle, map out the full complex value of the quantum overlap integral $\mathcal{O}$. This elevates the model from a simple comparative device to a complete diagnostic tool for probing the deep structure of holosymmetric evolution.

Interference Expectation in the Asymmetric Interferometer Model

Corollary 3.7 (Interference Expectation: Asymmetric Interferometer)**.** *Let* $\mathbf{U}_{holo}^{(asym)} := \mathbf{U}_{read} \cdot \mathbf{U}_{ctrl} \cdot \mathbf{U}_{prep}$ *be the Asymmetric Interferometer Holosymmetric Operator (Definition 2.124), acting on the holosymmetric Hilbert space* $\mathcal{H}_{\mathrm{Holo}}$*. Suppose the system is initialized in the product state:*

$$|\Psi_{\mathrm{init}}\rangle := |\mathbf{0}\rangle_c \otimes |\Psi_{\mathrm{RR}}\rangle,$$

where $|\Psi_{\mathrm{RR}}\rangle \in \mathcal{H}_{\mathrm{RR}}^{(2n)}$ *is a normalized state of the dual PQS registers, and* $|\mathbf{0}\rangle_c \in \mathcal{H}_c$ *is the initial control state.*

Then the probability $p_0^{(asym)}$ *of observing the control system in state* $|\mathbf{0}\rangle_c$ *after evolution under* $\mathbf{U}_{holo}^{(asym)}$ *is given by:*

$$\boxed{p_0^{(asym)} = \left\| \left(\gamma\alpha \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^* \beta \, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \right) |\Psi_{\mathrm{RR}}\rangle \right\|^2,} \tag{3.3}$$

where the complex coefficients $\alpha, \beta, \gamma, \delta$ *are the matrix elements of the preparation gate* U_c^{prep} *and readout gate* U_c^{read}*, respectively.*

Interpretation. *In the asymmetric model, the measurement outcome is governed by a tunable, coherent superposition of the two evolutionary paths. The final probability depends not only on the intrinsic properties of the path operators but also explicitly on the choice of*

preparation and measurement bases for the control system. This allows the interferometer to function as a tomographic device, capable of mapping out the full complex quantum overlap between the two histories by systematically varying the gate parameters.

Proof of Corollary Corollary 3.7. The goal is to derive the probability, $p_0^{(\text{asym})}$, of measuring the control qubit in the state $|\mathbf{0}\rangle_c$ after the system evolves under the formally defined Asymmetric Interferometer Holosymmetric Operator.

We begin with the initial state:

$$|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle,$$

where $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ is a normalized state of the dual PQS registers.

The full evolution is governed by the operator:

$$\mathbf{U}_{\text{holo}}^{(\text{asym})} := \mathbf{U}_{\text{read}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{prep}}.$$

The derivation proceeds in three acts.

Act I: Asymmetric Preparation. The arbitrary preparation gate $\mathbf{U}_{\text{prep}} = U_c^{\text{prep}} \otimes I_{\text{RR}}$ acts on the initial state, creating a general superposition:

$$\begin{aligned} |\Psi_{\text{prep}}\rangle &:= \mathbf{U}_{\text{prep}} |\Psi_{\text{init}}\rangle \\ &= (\alpha\,|\mathbf{0}\rangle_c + \beta\,|\mathbf{1}\rangle_c) \otimes |\Psi_{\text{RR}}\rangle. \end{aligned}$$

Act II: Differential Evolution. The controlled evolution operator $\mathbf{U}_{\text{ctrl}}$ then applies the two distinct dynamical paths to the corresponding branches of the superposition:

$$\begin{aligned} |\Psi_{\text{entangled}}\rangle &:= \mathbf{U}_{\text{ctrl}} |\Psi_{\text{prep}}\rangle \\ &= \alpha\,|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} |\Psi_{\text{RR}}\rangle + \beta\,|\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} |\Psi_{\text{RR}}\rangle. \end{aligned}$$

Act III: Asymmetric Recombination. Finally, the arbitrary readout gate $\mathbf{U}_{\text{read}} = U_c^{\text{read}} \otimes I_{\text{RR}}$ acts on the control qubit, projecting the interfered state onto the final measurement basis:

$$\begin{aligned} |\Psi_{\text{final}}\rangle &:= \mathbf{U}_{\text{read}} |\Psi_{\text{entangled}}\rangle \\ &= |\mathbf{0}\rangle_c \otimes \left(\gamma\alpha\,\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^*\beta\,\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) |\Psi_{\text{RR}}\rangle \\ &\quad + |\mathbf{1}\rangle_c \otimes \left(\delta\alpha\,\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\,\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) |\Psi_{\text{RR}}\rangle. \end{aligned}$$

To find the probability $p_0^{(\text{asym})}$, we project this final state onto $|\mathbf{0}\rangle_c$ and compute the squared norm of the amplitude:

$$p_0^{(\text{asym})} = \| \langle \mathbf{0}|_c |\Psi_{\text{final}}\rangle \|^2 = \left\| \left(\gamma\alpha\,\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^*\beta\,\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) |\Psi_{\text{RR}}\rangle \right\|^2.$$

This is precisely the expression given in Corollary Corollary 3.7. □

3.1.6 Asymmetric Complementary Interference Probability

Proof. We seek to derive the probability, $p_1^{(\text{asym})}$, of measuring the control qubit in the state $|\mathbf{1}\rangle_c$. This is the complementary outcome to the probability $p_0^{(\text{asym})}$ derived in the proof of Corollary Corollary 3.7.

We begin with the correctly derived final state of the system after the action of the Asymmetric Interferometer Holosymmetric Operator, $\mathbf{U}_{\text{holo}}^{(\text{asym})}$:

$$\begin{aligned}|\Psi_{\text{final}}\rangle =&|\mathbf{0}\rangle_c \otimes \left(\gamma\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^*\beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle \\ &+|\mathbf{1}\rangle_c \otimes \left(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\end{aligned}$$

To find the probability $p_1^{(\text{asym})}$, we project this final state onto the desired outcome $|\mathbf{1}\rangle_c$ and compute the squared norm of the resulting amplitude:

$$p_1^{(\text{asym})} = \left\|\langle\mathbf{1}|_c|\Psi_{\text{final}}\rangle\right\|^2.$$

Performing the projection isolates the amplitude for the '$|\mathbf{1}\rangle_c$' branch:

$$\langle\mathbf{1}|_c|\Psi_{\text{final}}\rangle = \left(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle.$$

Taking the squared norm gives the final expression for the probability:

$$p_1^{(\text{asym})} = \left\|\left(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^*\beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)|\Psi_{\text{RR}}\rangle\right\|^2.$$

Consistency via Unitarity. As a necessary check, the total probability $p_0^{(\text{asym})} + p_1^{(\text{asym})}$ must sum to one. Let $\hat{U}_A = \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{U}_B = \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$. Expanding the norms for p_0 and p_1:

$$\begin{aligned}p_0 &= \langle\Psi_{\text{RR}}|(\gamma^*\alpha^*\hat{U}_A^\dagger - \delta\beta^*\hat{U}_B^\dagger)(\gamma\alpha\hat{U}_A - \delta^*\beta\hat{U}_B)|\Psi_{\text{RR}}\rangle \\ &= |\gamma\alpha|^2 + |\delta\beta|^2 - 2\text{Re}(\gamma\alpha\beta\delta\langle\Psi_{\text{RR}}|\hat{U}_B^\dagger\hat{U}_A|\Psi_{\text{RR}}\rangle)\end{aligned}$$

$$\begin{aligned}p_1 &= \langle\Psi_{\text{RR}}|(\delta^*\alpha^*\hat{U}_A^\dagger + \gamma\beta^*\hat{U}_B^\dagger)(\delta\alpha\hat{U}_A + \gamma^*\beta\hat{U}_B)|\Psi_{\text{RR}}\rangle \\ &= |\delta\alpha|^2 + |\gamma\beta|^2 + 2\text{Re}(\delta\alpha\beta\gamma\langle\Psi_{\text{RR}}|\hat{U}_A^\dagger\hat{U}_B|\Psi_{\text{RR}}\rangle)\end{aligned}$$

Summing these probabilities, the cross-terms involving the quantum overlap integral cancel perfectly:

$$\begin{aligned}p_0 + p_1 &= |\alpha|^2(|\gamma|^2 + |\delta|^2) + |\beta|^2(|\delta|^2 + |\gamma|^2) \\ &= |\alpha|^2(1) + |\beta|^2(1) = 1,\end{aligned}$$

where we have used the unitarity conditions $|\alpha|^2 + |\beta|^2 = 1$ and $|\gamma|^2 + |\delta|^2 = 1$ for the preparation and readout gates. This confirms the internal consistency of our formulation. □

3.1.7 Visibility of Holosymmetric Interference: Asymmetric Interferometer Model

Theorem 3.8 (Visibility of Holosymmetric Interference: Asymmetric Interferometer)**.** *Consider the asymmetric holosymmetric interferometric configuration described in Corollary Corollary 3.7 and its complementary proof. Let the initial state be:*

$$|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle,$$

where $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ *is normalized. The system evolves under the Asymmetric Interferometer Holosymmetric Operator* $\mathbf{U}_{holo}^{(asym)}$*, and the control qubit is measured in the computational basis, yielding outcomes* $p_0^{(asym)}$ *and* $p_1^{(asym)}$*.*

The holosymmetric interference visibility *for the asymmetric interferometer model is defined as the absolute difference in outcome probabilities:*

$$\mathcal{V}_{\text{asym}} := \left| p_0^{(asym)} - p_1^{(asym)} \right|.$$

Substituting the correct expressions for the probabilities, the visibility is given explicitly by:

$$\boxed{\begin{aligned}\mathcal{V}_{\text{asym}} = \Bigg| & \left\| \left(\gamma\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle \right\|^2 \\ & - \left\| \left(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle \right\|^2 \Bigg|,\end{aligned}} \tag{3.4}$$

where the complex coefficients $\alpha, \beta, \gamma, \delta$ *are the matrix elements of the preparation gate* U_c^{prep} *and readout gate* U_c^{read}*, respectively.*

Interpretation. *In the asymmetric model, the visibility is a tunable functional that depends on the experimenter's choice of preparation and readout bases. Unlike the symmetric case, which yields a single visibility value, this model allows one to probe different aspects of the quantum overlap between the two evolutionary histories. By systematically varying the gate parameters, one can design the experiment to be sensitive to either the real or imaginary parts of the overlap integral* $\langle \Psi_{\text{RR}} | \hat{\mathbf{U}}_B^\dagger \hat{\mathbf{U}}_A | \Psi_{\text{RR}} \rangle$*, thereby performing a full tomographic reconstruction of the relational coherence between the two universal histories.*

Proof of Theorem Theorem 3.8. The proof proceeds directly from the definition of visibility and the corrected expressions for the measurement probabilities $p_0^{(\text{asym})}$ and $p_1^{(\text{asym})}$, which were derived from the action of the formal Asymmetric Interferometer Holosymmetric Operator, $\mathbf{U}_{\text{holo}}^{(\text{asym})} = \mathbf{U}_{\text{read}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{prep}}$.

The probabilities for the two outcomes of the control qubit measurement are given by:

$$\begin{aligned} p_0^{(\text{asym})} &= \left\| \left(\gamma\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle \right\|^2, \\ p_1^{(\text{asym})} &= \left\| \left(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) |\Psi_{\text{RR}}\rangle \right\|^2. \end{aligned}$$

The visibility is defined as the absolute difference between these probabilities:

$$\mathcal{V}_{\text{asym}} := \left| p_0^{(\text{asym})} - p_1^{(\text{asym})} \right|.$$

Substituting the expressions for the probabilities directly into this definition yields:

$$\mathcal{V}_{\text{asym}} = \Big| \Big\| \Big(\gamma\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \delta^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\Big) |\Psi_{\text{RR}}\rangle \Big\|^2 - \Big\| \Big(\delta\alpha\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \gamma^* \beta\, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\Big) |\Psi_{\text{RR}}\rangle \Big\|^2 \Big|.$$

This is precisely the visibility expression given in the corrected Theorem 3.8, thereby completing the proof. □

3.1.8 Interferometric Visibility Bounds

Setting. We work in the holosymmetric double-slit apparatus of Section 3.1, with control–qubit preparation and readout gates $U_c^{\text{prep}}, U_c^{\text{read}} \in \text{SU}(2)$ realizing the symmetric and asymmetric regimes (Sections 3.1.1 and 3.1.5). The total Hilbert space is $\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)}$, where $\mathcal{H}_c \cong \mathbb{C}^2$ is the control system and $\mathcal{H}_{\text{RR}}^{(2n)}$ is the dual PQS–register space (RR = "dual PQS Registers"), with joint register states $|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ as in Definition 2.113. Controlled holosymmetric evolution prepares two alternative path–histories on the registers, represented either by *pure* states $|\psi_a\rangle, |\psi_b\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$ or by *mixed* states $\rho_a, \rho_b \in \mathcal{D}(\mathcal{H}_{\text{RR}}^{(2n)})$ (see the path operators in Definition 2.108).

With single-qubit readout (Section 3.1.2), we include an adjustable reference phase $\phi \in \mathbb{R}$ on the control (equivalently, a choice of readout axis), and monitor the *fringe intensity*

$$I(\phi) \;=\; \tfrac{1}{2}\Big(1 + \text{Re}\big[e^{i\phi}\,\mathcal{M}\big]\Big), \qquad \mathcal{M} \;=\; \begin{cases} \langle\psi_a|\psi_b\rangle, & \text{pure histories,} \\ \text{Tr}\Big(\sqrt{\rho_a}\,\sqrt{\rho_b}\,U_{\text{rel}}\Big), & \text{mixed histories,} \end{cases}$$

where U_{rel} is the (experimentally controlled) *relative unitary* on the joint support of ρ_a, ρ_b induced by the chosen readout in the asymmetric setting (take $U_{\text{rel}} = \mathbb{I}$ in the symmetric case; cf. Section 3.1.5). The *visibility* is

$$\mathcal{V} \;:=\; \frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}} \in [0, 1],$$

so that in the symmetric regime one has $\mathcal{V} = |\mathcal{M}|$ (Section 3.1.2). This calculus follows the Pancharatnam–Berry–Anandan two-path phase/coherence lineage [23, 24, 25] and the Born-valued semantics adopted in Section 1.2.9.

$\mathcal{M}$ (overlap amplitude). Complex interference overlap of the two prepared path–histories; $\mathcal{M} = \langle\psi_a|\psi_b\rangle$ for pure histories and $\mathcal{M} = \text{Tr}(\sqrt{\rho_a}\sqrt{\rho_b}\,U_{\text{rel}})$ for mixed histories (in the symmetric readout, $\mathcal{V} = |\mathcal{M}|$); cf. Sections 3.1.2 and 3.1.5. **$\mathcal{D}(\mathcal{H})$.** Set of density operators on Hilbert space $\mathcal{H}$ (positive, trace one). **U_{rel}.** Relative unitary induced by the readout choice; identity in the symmetric case.

1) Pure Histories: Baseline and Triadic Bounds. For the symmetric Mach–Zehnder regime (Section 3.1.1), where the overlap amplitude is $\mathcal{M} = \langle\psi_a|\psi_b\rangle$,

$$\boxed{\mathcal{V} \;=\; |\mathcal{M}| \;=\; |\langle\psi_a|\psi_b\rangle| \;\leq\; 1} \,. \tag{3.5}$$

For general (possibly unbalanced) $SU(2)$ settings (Sections 3.1.5 and 3.1.7),

$$\boxed{\mathcal{V} \;\le\; |\langle\psi_a|\psi_b\rangle|}\,, \tag{3.6}$$

with equality when the beam–splitter weights equalise the path priors (standard two–path algebra in the Pancharatnam–Berry–Anandan framework [23, 24, 25]).

Triadic resolution. Let $P_{\mathrm{corr}}, P_{\mathrm{vac}}, P_{\mathrm{spec}}$ be the orthogonal projectors induced by the Unified Inter–Modal Correlator (Definition 6.4), so that $\sum_\chi P_\chi = \mathbb{I}$ and $P_\chi P_{\chi'} = \delta_{\chi\chi'} P_\chi$, with $\chi \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\}$. Define triadic overlap components

$$\mathcal{M}_\chi \;:=\; \langle\psi_a|\, P_\chi \,|\psi_b\rangle, \qquad \chi \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\}, \tag{3.7}$$

so that $\langle\psi_a|\psi_b\rangle = \sum_\chi \mathcal{M}_\chi$. Two instrument–level envelopes follow:

(i) *Universal bound (no extra control):*

$$\boxed{\mathcal{V} \;\le\; \Big|\textstyle\sum_\chi \mathcal{M}_\chi\Big| \;\le\; \sum_\chi |\mathcal{M}_\chi|}\,. \tag{3.8}$$

(ii) *Triadically weighted bound (with channel weights).* Implement a readout that applies complex weights w_χ with $\sum_\chi |w_\chi|^2 = 1$ (operationally: pre/post–multiply by $\sum_\chi w_\chi P_\chi$; cf. Section 12.2). The fringe amplitude then becomes

$$\mathcal{M}(w) \;=\; \sum_\chi w_\chi\, \mathcal{M}_\chi,$$

and by Cauchy–Schwarz [356]

$$|\mathcal{M}(w)| \;=\; \Big|\textstyle\sum_\chi w_\chi \mathcal{M}_\chi\Big| \;\le\; \Big(\sum_\chi |\mathcal{M}_\chi|^2\Big)^{1/2}. \tag{3.9}$$

Choosing $w_\chi \propto \overline{\mathcal{M}_\chi}$ yields the optimal envelope

$$\boxed{\mathcal{V}_{\max} \;\le\; \Big(|\mathcal{M}_{\mathrm{corr}}|^2 + |\mathcal{M}_{\mathrm{vac}}|^2 + |\mathcal{M}_{\mathrm{spec}}|^2\Big)^{1/2}}\,. \tag{3.10}$$

Measurement note. Each $\mathcal{M}_\chi$ is the expectation of the effect $E_\chi := P_\chi|\psi_b\rangle\langle\psi_a|$ in the experiment's GNS state (Section 1.4.2); operationally, $|\mathcal{M}_\chi|$ is obtained by inserting P_χ in one arm and scanning the phase [355].

2) Mixed Histories: Fidelity Bounds and Triadic Additivity. Let $\rho_a, \rho_b \in \mathcal{D}(\mathcal{H}_{\mathrm{RR}}^{(2n)})$ be (possibly mixed) path states. In the mixed setting the overlap amplitude reads

$$\mathcal{M}(U_{\mathrm{rel}}) \;=\; \mathrm{Tr}\Big(\sqrt{\rho_a}\,\sqrt{\rho_b}\,U_{\mathrm{rel}}\Big), \qquad U_{\mathrm{rel}} \in \mathrm{U}(\mathrm{supp}\,\rho_a \cup \mathrm{supp}\,\rho_b),$$

with $U_{\mathrm{rel}} = \mathbb{I}$ in the symmetric readout (Section 3.1.1) and general SU(2) control in the asymmetric case (Section 3.1.5). By the polar decomposition $\sqrt{\rho_a}\sqrt{\rho_b} = V\,\big|\sqrt{\rho_a}\sqrt{\rho_b}\big|$, we have

$$|\mathcal{M}(U_{\mathrm{rel}})| \;\le\; \mathrm{Tr}\Big|\sqrt{\rho_a}\sqrt{\rho_b}\Big|,$$

with equality for $U_{\rm rel} = V^\dagger$. Using the Uhlmann fidelity [357, 287, 358]

$$F(\rho_a, \rho_b) \;:=\; \Big(\operatorname{Tr} \sqrt{\sqrt{\rho_a}\, \rho_b \, \sqrt{\rho_a}} \Big)^2 ,$$

and the identity $\operatorname{Tr}\big|\sqrt{\rho_a}\sqrt{\rho_b}\big| = \operatorname{Tr} \sqrt{\sqrt{\rho_a}\rho_b\sqrt{\rho_a}} = \sqrt{F(\rho_a,\rho_b)}$ [359, 357], it follows that

$$\boxed{\; \mathcal{V} \;=\; |\mathcal{M}(U_{\rm rel})| \;\le\; \sqrt{F(\rho_a,\rho_b)} \;\le\; 1 \;}\,. \tag{3.11}$$

(In the symmetric readout $U_{\rm rel} = \mathbb{I}$, one has $|\mathcal{M}(\mathbb{I})| \le \sqrt{F(\rho_a,\rho_b)}$; the upper bound is saturated when $\sqrt{\rho_a}\sqrt{\rho_b}$ is positive or when $U_{\rm rel}$ is chosen optimally via the polar part $V^\dagger$ [287, 358].)

Triadic resolution via pinching. Let $P_{\rm corr}, P_{\rm vac}, P_{\rm spec}$ be the orthogonal projectors from the Unified Inter–Modal Correlator (Definition 6.4), and define the CPTP "triadic pinching" channel

$$\mathcal{P}(\cdot) \;=\; \sum_{\chi \in \{\rm corr,vac,spec\}} P_\chi(\cdot)P_\chi, \qquad \text{(cf. Section 12.2)}.$$

What this means. The map $\mathcal{P}$ is a completely positive trace-preserving (CPTP) quantum channel with Kraus operators $K_\chi = P_\chi$:

$$\mathcal{P}(X) = \sum_\chi K_\chi X K_\chi^\dagger, \quad K_\chi = P_\chi, \quad \sum_\chi K_\chi^\dagger K_\chi = \sum_\chi P_\chi = \mathbb{I},$$

hence CP and TP (Choi–Jamiołkowski/Kraus criteria [360, 361, 287]). Operationally, $\mathcal{P}$ is a *non-selective projective measurement (or complete dephasing)* in the triadic sector label χ: it *removes inter-sector coherences* while *preserving* sector populations and total trace. Algebraically, $\mathcal{P}$ is the conditional expectation onto the block-diagonal subalgebra $\bigoplus_\chi P_\chi \mathcal{B}(\mathcal{H}) P_\chi$. After pinching, the states become block-diagonal,

$$\mathcal{P}(\rho_a) = \bigoplus_\chi \rho_a^\chi, \quad \rho_a^\chi := P_\chi \rho_a P_\chi, \qquad \mathcal{P}(\rho_b) = \bigoplus_\chi \rho_b^\chi,$$

and monotonicity of fidelity under CPTP maps yields [287, 358]

$$F(\rho_a,\rho_b) \;\le\; F\Big(\mathcal{P}(\rho_a), \mathcal{P}(\rho_b)\Big). \tag{3.12}$$

Because fidelity factorizes across orthogonal blocks,

$$\sqrt{F\Big(\mathcal{P}(\rho_a), \mathcal{P}(\rho_b)\Big)} \;=\; \sum_{\chi \in \{\rm corr,vac,spec\}} \sqrt{F\Big(\rho_a^\chi, \rho_b^\chi\Big)}. \tag{3.13}$$

Therefore the mixed–state visibility obeys the triadic envelope

$$\boxed{\; \mathcal{V} \;\le\; \sqrt{F(\rho_a,\rho_b)} \;\le\; \sum_{\chi \in \{\rm corr,vac,spec\}} \sqrt{F\Big(\rho_a^\chi, \rho_b^\chi\Big)} \;}\,. \tag{3.14}$$

Notes. (i) $\mathcal{P}$ can be implemented physically by inserting a non-selective sector measurement (or engineered dephasing) before readout; it leaves marginal sector weights unchanged while erasing cross-sector interference. (ii) The block factorization follows from $\sqrt{A \oplus B} = \sqrt{A} \oplus \sqrt{B}$ and $\operatorname{Tr}(X \oplus Y) = \operatorname{Tr} X + \operatorname{Tr} Y$.

3) Corollaries and Experimental Use. Write the triadic components of the overlap amplitude as

$$\mathcal{M}_\chi := \begin{cases} \langle\psi_a|P_\chi|\psi_b\rangle, & \text{pure histories,} \\ \mathrm{Tr}\big(\sqrt{\rho_a}\,P_\chi\,\sqrt{\rho_b}\,U_{\mathrm{rel}}\big), & \text{mixed histories,} \end{cases} \qquad \chi \in \{\mathrm{corr}, \mathrm{vac}, \mathrm{spec}\},$$

with $\mathcal{M} = \sum_\chi \mathcal{M}_\chi$, where P_χ are the sector projectors from Definition 6.4. A *triadic filter* means either a coherent weighting $W = \sum_\chi w_\chi P_\chi$ with $\sum_\chi |w_\chi|^2 = 1$, or the CPTP pinching $\mathcal{P}(\cdot) = \sum_\chi P_\chi(\cdot)P_\chi$ (cf. Sections 12.2 and 15.1.4).

Corollary 3.9 (Consistency strip)**.** *For any triadic filter,*

$$\mathcal{V} \;\le\; \min\Big\{\, |\mathcal{M}|,\; \textstyle\sum_\chi |\mathcal{M}_\chi|,\; \Big(\sum_\chi |\mathcal{M}_\chi|^2\Big)^{1/2},\; \sqrt{F(\rho_a,\rho_b)}\,\Big\}.$$

A *triadic filter* (sector-resolving operation) means either a coherent weighting $W = \sum_\chi w_\chi P_\chi$ with $\sum_\chi |w_\chi|^2 = 1$, or the CPTP pinching $\mathcal{P}(\cdot) = \sum_\chi P_\chi(\cdot)P_\chi$.

Proof. The baseline bound $\mathcal{V} \le |\mathcal{M}|$ is from the symmetric two-path calculus in Section 3.1.8. Sector resolution yields $|\mathcal{M}| \le \sum_\chi |\mathcal{M}_\chi|$ and, with coherent weights, $\max_{\|w\|_2=1} |\sum_\chi w_\chi \mathcal{M}_\chi| = (\sum_\chi |\mathcal{M}_\chi|^2)^{1/2}$ by Cauchy–Schwarz [356]. For mixed histories, $\mathcal{V} \le \sqrt{F(\rho_a,\rho_b)}$ follows from the Uhlmann fidelity bound in Paragraph 2 (Section 3.1.8; [357, 287, 358]). For pure histories $F(\rho_a,\rho_b) = |\mathcal{M}|^2$, so the strip specializes consistently. □

Corollary 3.10 (Channel dominance test)**.** *If* $|\mathcal{M}_{\mathrm{vac}}|, |\mathcal{M}_{\mathrm{spec}}| \ll |\mathcal{M}_{\mathrm{corr}}|$*, then*

$$\mathcal{V}_{\max} \;\le\; \Big(|\mathcal{M}_{\mathrm{corr}}|^2 + |\mathcal{M}_{\mathrm{vac}}|^2 + |\mathcal{M}_{\mathrm{spec}}|^2\Big)^{1/2} \;\approx\; |\mathcal{M}_{\mathrm{corr}}|.$$

Proof. Use the ℓ^2 envelope from Section 3.1.8 and neglect subleading terms when the non-correlation sectors are suppressed. The approximation sign reflects the small-parameter regime. □

Corollary 3.11 (Selection–principle tie–in)**.** *In Stage–II comparative tomography (Section 12.2) under a fixed triadic filter, the configuration with the brightest interference fringe maximizes the* ℓ^2 *envelope* $\big(\sum_\chi |\mathcal{M}_\chi|^2\big)^{1/2}$*, rather than* $|\sum_\chi \mathcal{M}_\chi|$.

Proof. With coherent weighting $W = \sum_\chi w_\chi P_\chi$ ($\sum_\chi |w_\chi|^2 = 1$), the achievable amplitude is $\mathcal{M}(w) = \sum_\chi w_\chi \mathcal{M}_\chi$, whose maximum modulus is the ℓ^2 norm by Cauchy–Schwarz [356]. This objective is immune to accidental inter-sector phase cancellations that can depress $|\sum_\chi \mathcal{M}_\chi|$. □

4) Implementation Narrative. *How to read and use the bounds in practice.* Begin with the actual interferometer we can build: fix the SU(2) preparation/readout on the control (Sections 3.1.1 and 3.1.5) and extract the measured visibility $\mathcal{V}$ from the fringe $I(\phi)$ (Section 3.1.8). If the prepared histories are effectively pure, the baseline inequality from Paragraph 1 already constrains the signal by the overlap amplitude $|\mathcal{M}|$; if they are mixed (or suspected to be), the fidelity bound caps $\mathcal{V}$ by $\sqrt{F(\rho_a,\rho_b)}$ (see Section 3.1.8). To diagnose *where* coherence

lives, do not chase a single complex sum; instead, resolve the amplitude into triadic sectors with the projectors P_χ from Definition 6.4 and consult the sector envelopes: the ℓ^1 bound detects diffuse, phase-sensitive contributions, while the ℓ^2 (Cauchy–Schwarz) envelope records intrinsic sectoral strength and is robust against inter-sector phase cancellations (Corollary 3.9; [356]). For mixed histories, the same sector resolution is implemented cleanly by the CPTP triadic pinching $\mathcal{P}(\cdot) = \sum_\chi P_\chi(\cdot)P_\chi$, whose fidelity monotonicity and block factorization yield a transparent, additively interpretable ceiling on $\mathcal{V}$ (Sections 3.1.8 and 15.1.4; [287, 358]). In practice, a small vac/spec contribution relative to corr signals channel dominance (Corollary 3.10); and for control design or model selection, the "winner" under fixed filters is the configuration maximizing the ℓ^2 envelope rather than the raw complex sum (Corollary 3.11).

These inequalities are *instrument–level*: they require only the Born semantics of Section 1.2.9 and the existence of the triadic projectors from Definition 6.4. They connect directly to laboratory interferometry [23, 24, 25] and thus furnish clean pass/fail criteria for any proposal claiming large holosymmetric effects.

3.1.9 The Interferometer of Universal Histories

The double-slit experiment, that cornerstone demonstration of quantum mechanics, reveals how a single particle can traverse multiple paths simultaneously, creating interference patterns that encode the fundamental wave-particle duality of nature. In IQR framework, this principle undergoes a profound generalization: the "particle" becomes an entire dual-universe system, the "slits" become complementary evolutionary histories, and the "interference pattern" emerges as the observable structure of reality itself.

This conceptual mapping transforms our understanding of quantum interference from a microscopic phenomenon to a cosmological principle. Through the Holosymmetric Interferometer Model (Section 2.4), we discover that the universe may be continuously performing a meta-double-slit experiment upon itself, with physical laws emerging as stable interference patterns between competing evolutionary possibilities.

The Fundamental Analogy: Mapping Quantum Concepts Across Scales The correspondence between the classic double-slit experiment and the Holosymmetric Interferometer Model reveals a deep structural similarity:

Classic Double-Slit	**Holosymmetric Interferometer Model**
The Particle (e.g., electron)	The Dual-Register PQS State $\|\Psi_{\text{RR}}\rangle \in \mathcal{H}_{\text{RR}}^{(2n)}$
The Two Slits (spatial apertures)	The Two Evolutionary Paths: $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$
The Detector Screen	The Control Qubit $\mathcal{H}_c = \text{span}\{\|\mathbf{0}\rangle_c, \|\mathbf{1}\rangle_c\}$
Interference Fringes	Measurement Probabilities p_0 and p_1
Wave Function	The Holosymmetric State Evolution

Table 3.1: The foundational analogy between the classic double-slit experiment and the Holosymmetric Interferometer Model, mapping quantum concepts across scales from particle mechanics to universal evolution.

This analogical mapping also represents a fundamental principle of the IQR wherein quantum interference operates at the level of entire cosmological configurations.

The Symmetric Interferometer: A Measure of Relational Symmetry

Theoretical Foundation: The Three Acts of the Interferometer In the symmetric model, we implement a perfect complementarity between two evolutionary pathways. The experimental protocol unfolds through three critical stages:

1. *Act I: Path Creation.* Starting with the system in a simple basis state, $|\Psi_{\text{initial}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$, the first Hadamard gate $\mathbf{U}_{\text{Had}}$ creates a coherent superposition of the two control states. This prepares the system to traverse both evolutionary paths simultaneously.

2. *Act II: Differential Evolution.* The controlled-unitary operator $\mathbf{U}_{\text{ctrl}}$ applies a different dynamical law to each branch of the superposition. The $|\mathbf{0}\rangle_c$ component evolves via "Slit 1" ($\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$), while the $|\mathbf{1}\rangle_c$ component evolves via "Slit 2" ($\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$).

3. *Act III: Recombination & Measurement.* A final Hadamard gate recombines the paths, causing them to interfere. A measurement on the control qubit reveals the outcome, with the probabilities given by:

$$p_0 = \frac{1}{4} \left\| \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) \|\Psi_{\text{RR}}\rangle \right\|^2$$

$$p_1 = \frac{1}{4} \left\| \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) \|\Psi_{\text{RR}}\rangle \right\|^2$$

Physical Interpretation The measurement outcomes encode a profound physical reality:

- p_0 *(Bright Fringe)*: The probability of constructive interference between evolutionary histories.

- p_1 *(Dark Fringe)*: The probability of destructive interference between evolutionary histories.

The visibility $\mathcal{V}_{\text{sym}} = |p_0 - p_1| = \left|\text{Re}\left(\langle\Psi_{\text{RR}}|\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G\dagger}\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle\right)\right|$ quantifies the degree of functional symmetry between the two dynamics as they act on the initial state.

The Asymmetric Interferometer: Quantum Tomography of Histories The asymmetric model generalizes the symmetric case by replacing the fixed Hadamard gates with arbitrary preparation and readout gates, $\mathbf{U}_{\text{prep}}$ and $\mathbf{U}_{\text{read}}$. The two evolutionary paths, or "slits," remain the same.

This configuration probes the interference between the two dynamic evolutions from any "angle" on the control qubit's Bloch sphere, as chosen by the experimenter.

The Tomographic Interpretation The asymmetric interferometer functions as a tool for *quantum process tomography*. The resulting measurement probabilities are complex functions of the gate parameters $(\alpha, \beta, \gamma, \delta)$ and the quantum overlap integral $\mathcal{O}$. By systematically varying the preparation and readout gates, one can map out the full complex value of $\mathcal{O}$, thereby performing a complete tomographic reconstruction of the quantum relationship between the two universal histories.

The Recursive Structure: Fractal Interference Patterns The profound innovation of the holosymmetric framework lies in its recursive structure. The statement "the architecture is recursive" refers to the fact that the evolutionary operators themselves, $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$, are not primitive. They are built from nested, composite parasymmetric generators. Therefore, the states that interfere in our experiment are already deeply structured and encode their own layered, relational histories.

This is distinct from a "second-order experiment", which would involve applying the entire interferometer operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ sequentially. The recursive nature is inherent in the building blocks of the theory.

The Self-Similar Structure of Reality This recursive structure suggests a fractal organization of quantum reality:

1. *Level 1: Interference of Quantum States.* This is the familiar interference of standard quantum mechanics. A particle's state is a superposition of passing through "slit A" and "slit B", and these possibilities interfere. This is the base pattern.

2. *Level 2: Interference of Evolutionary Histories.* Our Holosymmetric Interferometer elevates this principle. The "slits" are no longer spatial paths, but entire evolutionary histories ($\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$). We create a superposition of these two distinct dynamical laws and measure their interference. The *same principle of interference* is now acting on the laws of evolution themselves.

3. *Level 3: Recursive Structure of the Histories.* Here lies the deepest level of self-similarity. We find that the operators defining the histories ($\hat{\mathbf{U}}_{\text{RR}}$) are not primitive. They are

themselves recursively constructed from more fundamental local, pairwise, and global parasymmetric generators. The very building blocks of the Level 2 interference are themselves built from a nested, compositional logic.

The "fractal" nature of this reality lies in the repeating motif of *coherent superposition and interference*. This single quantum principle is applied to: (1) states, (2) processes that act on states, and (3)the very definition of those processes. The framework suggests a universe with a profound logical self-similarity, where the same quantum principle that governs the path of an electron also governs the superposition of cosmic histories and the structure of the laws that write them.

Fractal Reality and the Quantum Meta-Law The most profound prediction of this framework is that reality itself should bear the imprint of fractal organization at all scales—a testable hypothesis with specific observable consequences. The *cosmic web*, that vast filamentary structure of galaxies and dark matter spanning hundreds of millions of light-years, may be the most direct visualization of this principle. Rather than arising from stochastic gravitational clustering, the framework suggests these structures are *macroscopic manifestations of the underlying quantum entanglement network*—the filaments representing high-correlation pathways in the $\hat{\Omega}$-Continuum, with galaxies condensing at the most interconnected nodes [362, 147]. If true, detailed analysis of the cosmic web should reveal not just statistical self-similarity, but precise mathematical patterns that mirror the quantum interference structures at microscopic scales [31, 363].

This fractal principle extends to the deepest mysteries of particle physics, offering a stunning reinterpretation of the *three generations of matter*. Rather than arbitrary repetition, the electron-muon-tau hierarchy (and corresponding quark families) may represent *three self-similar manifestations of a single underlying principle at different energy scales*—just as a fractal contains smaller copies of itself [364]. This transforms the generation problem from "why three?" to "what is the scaling rule?"—a quantitative question amenable to experimental investigation. Similarly, the phenomenon of *running coupling constants* in quantum field theory, where fundamental "constants" vary with measurement energy, becomes not a technical complication but a deep geometric principle: the laws themselves are scale-dependent reflections of the fractal substrate from which they emerge [32].

The experimental program for testing this framework thus focuses on identifying *universal scaling laws* and *hierarchical interference patterns* across all domains of physics. We should find the same mathematical structures governing quantum decoherence times, galactic formation rates, and cosmic evolution epochs—properly normalized for scale. The CMB might contain nested interference patterns following the holosymmetric principle [365], while phase transitions from particle physics to cosmology should exhibit recursive symmetry breaking with identical mathematical forms [366]. This vision transforms physics from finding different laws at different scales to discovering how the *same meta-law* manifests universally—reality written in a self-similar quantum language where being and becoming unite through the eternal dance of quantum interference across all possible histories of the cosmos.

3.2 Interferometric Model Recursive Expansion

3.2.1 Recursive Component Expansion: Symmetric Interferometer

Let $\mathbf{U}_{\text{Had}} = H_c \otimes I_{\text{RR}}$, where:

$$H_c := \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix},$$

and let the controlled evolution operator be:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}.$$

Then the full symmetric holosymmetric operator is given by:

$$\mathbf{U}_{\text{holo}}^{(\text{sym})} := \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}}.$$

To express this in block form, we first recall the two distinct evolutionary path operators:

$$\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} := U_G^{(A)} \cdot U_N^{(B)}$$
$$\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} := U_N^{(A)} \cdot U_G^{(B)}$$

We also define the holosymmetric path sum and difference operators using this full notation:

$$\hat{\mathbf{U}}_+ := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$$
$$\hat{\mathbf{U}}_- := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$$

The matrix computation for $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ then proceeds:

$$\begin{aligned}
\mathbf{U}_{\text{holo}}^{(\text{sym})} &= \left(\frac{1}{\sqrt{2}} \begin{pmatrix} I & I \\ I & -I \end{pmatrix} \right) \begin{pmatrix} \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} & 0 \\ 0 & \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \end{pmatrix} \left(\frac{1}{\sqrt{2}} \begin{pmatrix} I & I \\ I & -I \end{pmatrix} \right) \\
&= \frac{1}{2} \begin{pmatrix} \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} & \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \\ \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} & \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \end{pmatrix} \\
&= \frac{1}{2} \begin{pmatrix} \hat{\mathbf{U}}_+ & \hat{\mathbf{U}}_- \\ \hat{\mathbf{U}}_- & \hat{\mathbf{U}}_+ \end{pmatrix}
\end{aligned}$$

We now write this operator in the computational basis as:

$$\mathbf{U}_{\text{holo}}^{(\text{sym})} = \sum_{i,j \in \{0,1\}} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \mathcal{F}_{ij}^{(\text{sym})},$$

where each component operator $\mathcal{F}_{ij}^{(\text{sym})} \in \mathcal{U}(\mathcal{H}_{\text{RR}}^{(2n)})$ is:

$$\boxed{\begin{aligned}
\mathcal{F}_{00}^{(\text{sym})} &= \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) && (3.15) \\
\mathcal{F}_{01}^{(\text{sym})} &= \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) && (3.16) \\
\mathcal{F}_{10}^{(\text{sym})} &= \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) && (3.17) \\
\mathcal{F}_{11}^{(\text{sym})} &= \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right) && (3.18)
\end{aligned}}$$

Interpretation. These components reveal that:

- The diagonal terms $\mathcal{F}_{00}^{(\mathrm{sym})}$ and $\mathcal{F}_{11}^{(\mathrm{sym})}$ preserve the control branch but apply symmetric recombination of path operators.
- The off-diagonal terms $\mathcal{F}_{01}^{(\mathrm{sym})}$ and $\mathcal{F}_{10}^{(\mathrm{sym})}$ transfer amplitude between the control basis states and encode the asymmetry between paths.

Thus, the operator $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ realizes a complete recursive interferometric transformation: it prepares a superposition, applies path-dependent dynamics, and recombines them, with its off-diagonal components enabling modal "scattering" between superposed histories.

3.2.2 Recursive Expansion: Asymmetric Interferometer

Let:

- $\mathbf{U}_{\mathrm{prep}} := U_c^{\mathrm{prep}} \otimes I_{\mathrm{RR}}$,
- $\mathbf{U}_{\mathrm{read}} := U_c^{\mathrm{read}} \otimes I_{\mathrm{RR}}$,

where $U_c^{\mathrm{prep}}, U_c^{\mathrm{read}} \in \mathrm{SU}(2)$ are parameterized as:

$$U_c^{\mathrm{prep}} = \begin{pmatrix} \alpha & -\beta^* \\ \beta & \alpha^* \end{pmatrix}, \qquad U_c^{\mathrm{read}} = \begin{pmatrix} \gamma & -\delta^* \\ \delta & \gamma^* \end{pmatrix}, \qquad |\alpha|^2 + |\beta|^2 = 1, \quad |\gamma|^2 + |\delta|^2 = 1.$$

The asymmetric holosymmetric operator is defined as:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{asym})} := \mathbf{U}_{\mathrm{read}} \cdot \mathbf{U}_{\mathrm{ctrl}} \cdot \mathbf{U}_{\mathrm{prep}},$$

with the control-dependent path evolution operator:

$$\mathbf{U}_{\mathrm{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.$$

We expand this over the computational basis $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$:

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{asym})} = \sum_{i,j\in\{0,1\}} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \mathcal{F}_{ij}^{(\mathrm{asym})},$$

where each component operator $\mathcal{F}_{ij}^{(\mathrm{asym})} \in \mathcal{U}(\mathcal{H}_{\mathrm{RR}}^{(2n)})$ governs the transition $|\mathbf{j}\rangle_c \to |\mathbf{i}\rangle_c$.

Explicit Expansion.

$$\boxed{\begin{aligned}
\mathcal{F}_{00}^{(\mathrm{asym})} &= \gamma\alpha \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^*\beta \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} && (3.19)\\
\mathcal{F}_{01}^{(\mathrm{asym})} &= -\gamma\beta^* \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^*\alpha^* \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} && (3.20)\\
\mathcal{F}_{10}^{(\mathrm{asym})} &= \delta\alpha \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \gamma^*\beta \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} && (3.21)\\
\mathcal{F}_{11}^{(\mathrm{asym})} &= -\delta\beta^* \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \gamma^*\alpha^* \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} && (3.22)
\end{aligned}}$$

Interpretation. Each $\mathcal{F}_{ij}^{(\text{asym})}$ is a linear combination of the two evolution operators, weighted by amplitudes from the input and output control rotations. This expansion:

- **Encodes the full SU(2) steering freedom**, via arbitrary U_c^{prep} and U_c^{read},
- **Represents modal transitions between control channels**, including cross-channel interference,
- **Generalizes symmetric holosymmetry**, enabling off-diagonal manipulation of coherence pathways.

Hence, the operator $\mathbf{U}_{\text{holo}}^{(\text{asym})}$ provides a complete formal framework for recursive control-modulated interference with asymmetric path coupling and control axis alignment.

3.2.3 Interpretations of the Component Expansions within the Double-Slit Analogy

The **Recursive Component Expansion** provides the mathematical engine for the Double-Slit Experiment. The matrix elements $\mathcal{F}_{ij}$ for the Interferometer Model are precisely the amplitudes for a system that enters the apparatus in control state $|j\rangle_c$ to exit in control state $|i\rangle_c$. They are the building blocks of the final interference pattern.

Symmetric Interferometer: The Amplitudes of the Fringes In the symmetric case, the operator is $\mathbf{U}_{\text{holo}}^{(\text{sym})}$, and its components have a beautifully direct interpretation. These components can be derived as a special case of the more general asymmetric formalism. The symmetric model is defined by the condition that both the preparation and readout gates are the Hadamard gate:

$$U_c^{\text{prep}} = U_c^{\text{read}} = H = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

We begin with the general formula for the component operators derived from the asymmetric model:

$$\mathcal{F}_{ij} = (U_c^{\text{read}})_{i0}(U_c^{\text{prep}})_{0j} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + (U_c^{\text{read}})_{i1}(U_c^{\text{prep}})_{1j} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$$

By substituting the matrix elements of the Hadamard gate ($H_{00} = H_{01} = H_{10} = 1/\sqrt{2}$ and $H_{11} = -1/\sqrt{2}$), we can calculate the specific components for the symmetric case.

For $\mathcal{F}_{00}^{(\text{sym})}$, we set $i = 0, j = 0$:

$$\begin{aligned}\mathcal{F}_{00}^{(\text{sym})} &= (H)_{00}(H)_{00} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + (H)_{01}(H)_{10} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \\ &= \left(\frac{1}{\sqrt{2}}\right)\left(\frac{1}{\sqrt{2}}\right)\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \left(\frac{1}{\sqrt{2}}\right)\left(\frac{1}{\sqrt{2}}\right)\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} = \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)\end{aligned}$$

For $\mathcal{F}_{10}^{(\text{sym})}$, we set $i = 1, j = 0$:

$$\begin{aligned}\mathcal{F}_{10}^{(\text{sym})} &= (H)_{10}(H)_{00} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + (H)_{11}(H)_{10} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \\ &= \left(\frac{1}{\sqrt{2}}\right)\left(\frac{1}{\sqrt{2}}\right)\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + \left(-\frac{1}{\sqrt{2}}\right)\left(\frac{1}{\sqrt{2}}\right)\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} = \frac{1}{2}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)\end{aligned}$$

This demonstrates how the general formalism elegantly simplifies in the symmetric case.

Interpretation of Symmetric Components

- $\mathcal{F}_{00}^{(\mathbf{sym})} = \frac{1}{2}(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})$: This is the operator-valued amplitude for a system starting in $|\mathbf{0}\rangle_c$ to be measured in $|\mathbf{0}\rangle_c$. It is proportional to the *constructive interference* term $\hat{\mathbf{U}}_+$. This corresponds to the amplitude of the *"bright fringe"* at the center of our detector screen.
- $\mathcal{F}_{10}^{(\mathbf{sym})} = \frac{1}{2}(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G})$: This is the amplitude for a system starting in $|\mathbf{0}\rangle_c$ to be measured in $|\mathbf{1}\rangle_c$. It is proportional to the *destructive interference* term $\hat{\mathbf{U}}_-$. This corresponds to the amplitude of the *"dark fringe"*.

The $\mathcal{F}_{01}$ and $\mathcal{F}_{11}$ components describe the same physical amplitudes but for a system initialized in the $|\mathbf{1}\rangle_c$ state.

Asymmetric Interferometer: Amplitudes for a "Polarized" Experiment In the more general asymmetric case, the $\mathcal{F}_{ij}^{(\mathrm{asym})}$ components are more complex because they must account for the arbitrary $SU(2)$ preparation and readout gates.

- $\mathcal{F}_{00}^{(\mathbf{asym})} = \gamma\alpha \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \delta^*\beta \cdot \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$: This is the amplitude for a system prepared in the state $\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c$ to be projected onto the final basis state $\gamma^*|\mathbf{0}\rangle_c - \delta|\mathbf{1}\rangle_c$ and found in the $|\mathbf{0}\rangle_c$ component.

This is analogous to a double-slit experiment with *polarizers*. The $\mathbf{U}_{\mathrm{prep}}$ gate acts as an initial polarizer that prepares the "particle" in a specific quantum state before it reaches the slits. The $\mathbf{U}_{\mathrm{read}}$ gate acts as a final analyzer before the detector. The $\mathcal{F}_{ij}^{(\mathrm{asym})}$ components are the resulting amplitudes for this fully "polarized" experiment, allowing us to perform a complete tomographic reconstruction of the interference process. In both cases, the component expansion provides the precise mathematical link between the abstract operator algebra and the measurable probabilities of our generalized double-slit experiment.

3.3 The Interferometric Commutator Lensing

While the standard Interferometer Model describes a process unfolding in time (Prepare → Evolve → Recombine), the *Commutator Lensing* offers a more profound, algebraic perspective. It shifts the explanation for interference from a sequential, time-based process to a direct manifestation of the non-commutation of core quantum operations. The commutator, $[\hat{A}, \hat{B}] = \hat{A}\hat{B} - \hat{B}\hat{A}$, measures the fundamental "tension" or "twist" one operation induces upon the other.

3.3.1 Commutator Lensing of the Symmetric Interferometer

Definition 3.12 (Symmetric Interferometer Commutator Lensing)**.** Let $\mathbf{U}_{\mathrm{ctrl}}$ be the controlled path operator and $\mathbf{U}_{\mathrm{Had}} = (H_c \otimes I_{\mathrm{RR}})$ be the Hadamard gate acting on the control system. Define the *commutator lensing of the symmetric holosymmetric operator*:

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{sym-com})} := [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}] \cdot \mathbf{U}_{\text{Had}}^{\dagger}.} \tag{3.23}$$

where:

- The commutator $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}]$ captures the *curvature* or failure of the preparation and evolution stages to commute.
- The post-multiplication by $\mathbf{U}_{\text{Had}}^{\dagger}$ returns the system to the preparation basis for final readout.

This operator acts nontrivially only if the path evolutions $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$ fail to symmetrically transform under H_c, thus encoding interference-induced asymmetry into the dynamics.

Here, the commutator $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}]$ isolates the essential quantum effect. It represents the difference between "evolving a superposition" ($\mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{Had}}$) and "superposing an evolution" ($\mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}}$). This difference is zero for a classical system but is the very source of interference in a quantum one. The operator thus measures the "curvature" in the space of operations induced by quantum mechanics. The subsequent multiplication by $\mathbf{U}_{\text{Had}}^{\dagger}$ simply rotates this abstract "twist" into a measurable basis.

3.3.2 Commutator Lensing of the Asymmetric Interferometer

Definition 3.13 (Asymmetric Interferometer Commutator Lensing)**.** Let $\mathbf{U}_{\text{prep}} = (U_c^{\text{prep}} \otimes I_{\text{RR}})$, $\mathbf{U}_{\text{read}} = (U_c^{\text{read}} \otimes I_{\text{RR}})$, and $\mathbf{U}_{\text{ctrl}}$ be defined as usual. The commutator lensing of the asymmetric holosymmetric operator is given by:

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{asym-com})} := [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] \cdot \mathbf{U}_{\text{read}}^{\dagger}.} \tag{3.24}$$

where:

- This operator quantifies how the chosen preparation basis fails to commute with the branching dynamics encoded in $\mathbf{U}_{\text{ctrl}}$.
- The readout transformation $\mathbf{U}_{\text{read}}^{\dagger}$ projects the result into a desired measurement basis.

This form generalizes the symmetric case and allows for experimental probing of interference asymmetries by comparing how path dynamics distort different interference bases.

Summary of Function The commutator formalism isolates the **dynamical twist** induced by interference. Specifically:

- $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}]$ in the symmetric case represents the algebraic torsion introduced by superposed branching.
- In the asymmetric case, $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]$ reflects how the branching structure fails to preserve the superposition geometry established by $\mathbf{U}_{\text{prep}}$.

The commutator $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]$ now asks a more sophisticated question: "How does the branching dynamic $\mathbf{U}_{\text{ctrl}}$ fail to preserve the specific superposition created by an arbitrary preparation $\mathbf{U}_{\text{prep}}$?" It quantifies the distortion or "shearing" of the initial quantum state geometry by the evolutionary process. The final $\mathbf{U}_{\text{read}}^{\dagger}$ allows us to view this distortion from any desired measurement perspective.

3.3.3 The Interferometric Commutator Lensing Double Slit Experiment

The operators we have defined, such as:

$$\mathbf{U}_{\text{holo}}^{(\text{sym-com})} := [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}] \cdot \mathbf{U}_{\text{Had}}^{\dagger}$$

provide a powerful theoretical lens. They tell us *what to look for*. They identify the fundamental source of the interesting dynamics—the "dynamical twist" caused by the failure of the preparation and evolution gates to commute.

The Experiments as the Method of Observation The advanced experiments we devised are the *operational protocols* for measuring the effects of that twist. Consider the core of the operator above, the commutator $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}]$. An experiment to probe it would involve:

1. *Path A:* Prepare an initial state $|\Psi\rangle$, act on it with $\mathbf{U}_{\text{ctrl}}$, and then $\mathbf{U}_{\text{Had}}$.
2. *Path B:* Prepare the same state $|\Psi\rangle$, act on it with $\mathbf{U}_{\text{Had}}$, and then $\mathbf{U}_{\text{ctrl}}$.
3. *Measurement:* Coherently measure the difference between the final states of Path A and Path B.

This experimental procedure is precisely what gives physical, measurable substance to the abstract algebraic definition of the commutator. The *Advanced Interferometric and Path Scattering Experiments* we designed are, in fact, the very protocols needed to measure the consequences of the non-commutativity described by the Commutator Formalism. In defining the commutators, we provide the profound insight that the "dynamical twist" is the key phenomenon. Devising the experiments provides the practical means to observe and quantify that twist. One is the theory, the other is its verification. Both are indispensable.

3.3.4 Experimental Protocols for the Commutator Lensing

The Commutator lensing formalism provides a profound theoretical lens, reframing interference as a direct consequence of the non-commutativity of quantum operations. The following protocols describe how one would operationally measure the "dynamical twist" isolated by these commutators. Each experiment is itself a meta-interferometer, designed to compare two distinct sequences of operations.

Probing the Symmetric Commutator

To measure the physical effect of the commutator $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}]$, which quantifies the tension between creating a symmetric superposition and evolving its branches. This requires a two-path experiment where each path corresponds to a different ordering of operations.

1. Preparation Prepare two identical systems in the same initial state, $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$, one for each arm of our meta-experiment.

2. Arm A (Evolve then Superpose) In this arm, the system evolves along a definite path *before* being placed into a superposition.

1. *Step A1 (Evolve):* First, apply the controlled evolution operator to produce the *evolved state*:
$$|\Psi_{\text{evolved}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$
2. *Step A2 (Superpose):* Second, apply the Hadamard operator to this evolved state to get the final state for Arm A:
$$|\Psi_{\text{E then S}}\rangle = \mathbf{U}_{\text{Had}}|\Psi_{\text{evolved}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle\right)$$

3. Arm B (Superpose then Evolve) In this arm, the system is placed in a superposition *before* the evolution is applied.

1. *Step B1 (Superpose):* First, apply the Hadamard operator to create the *prepared superposition*:
$$|\Psi_{\text{prep}}\rangle = \mathbf{U}_{\text{Had}}|\Psi_{\text{init}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes |\Psi_{\text{RR}}\rangle$$
2. *Step B2 (Evolve):* Second, apply the controlled evolution operator to this prepared state to get the final state for Arm B:
$$|\Psi_{\text{S then E}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{prep}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}|\Psi_{\text{RR}}\rangle\right)$$

4. Measurement The physical observable is the interference between the final states of the two arms, $|\Psi_{\text{E then S}}\rangle$ and $|\Psi_{\text{S then E}}\rangle$. A measurement of an observable $\hat{O}$ would yield an interference term proportional to $\text{Re}\langle\Psi_{\text{E then S}}|\hat{O}|\Psi_{\text{S then E}}\rangle$. The difference between the two final states is directly proportional to the action of the commutator: $|\Psi_{\text{S then E}}\rangle - |\Psi_{\text{E then S}}\rangle = [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]|\Psi_{\text{init}}\rangle$.

Interpretation This protocol directly measures the degree to which the order of operations matters. A non-zero interference signal between the two arms is the physical manifestation of the non-commutativity of the operators, providing a direct measurement of the "dynamical twist" at the heart of the interferometric process.

3.3.5 Probing the Asymmetric Commutator

To measure the physical effect of the commutator $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]$, which reveals how the branching dynamics of $\mathbf{U}_{\text{ctrl}}$ distort or "shear" an arbitrarily prepared superposition from $\mathbf{U}_{\text{prep}}$. This protocol requires a meta-interferometer that compares two parallel experimental arms.

1. Preparation Prepare two identical systems in the same initial state, $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$, one for each arm of the experiment.

2. Arm A: The Evolution of a Basis State This arm of the experiment first evolves the system along a definite path and *then* creates a superposition from the result.

1. *Step A1 (Evolve):* The system is first acted upon by the controlled evolution operator, forcing it down a single evolutionary path to produce the *evolved state*:

$$|\Psi_{\text{evolved}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$

2. *Step A2 (Prepare):* The arbitrary preparation gate $\mathbf{U}_{\text{prep}}$ now acts on this *already evolved* state:

$$|\Psi_{\text{E then P}}\rangle = \mathbf{U}_{\text{prep}}|\Psi_{\text{evolved}}\rangle = (\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle\right)$$

3. Arm B: The Evolution of a Superposition This arm reverses the order, first creating a superposition and then evolving it.

1. *Step B1 (Prepare):* The preparation gate $\mathbf{U}_{\text{prep}}$ acts on the initial state, immediately creating the *prepared superposition*:

$$|\Psi_{\text{prep}}\rangle = \mathbf{U}_{\text{prep}}|\Psi_{\text{init}}\rangle = (\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes |\Psi_{\text{RR}}\rangle$$

2. *Step B2 (Evolve):* The controlled evolution operator $\mathbf{U}_{\text{ctrl}}$ now acts on this pre-existing superposition:

$$|\Psi_{\text{P then E}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{prep}}\rangle = \alpha|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle + \beta|\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}|\Psi_{\text{RR}}\rangle$$

4. Measurement: Quantifying the Dynamical Twist The physical result of the experiment is the interference between the final states of the two arms, $|\Psi_{\text{E then P}}\rangle$ and $|\Psi_{\text{P then E}}\rangle$. Their difference is precisely the action of the commutator:

$$|\Psi_{\text{P then E}}\rangle - |\Psi_{\text{E then P}}\rangle = [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]|\Psi_{\text{init}}\rangle$$

This experiment directly contrasts two fundamentally different processes. The degree to which the two final states differ is a direct measure of the "algebraic curvature" that the evolution $\mathbf{U}_{\text{ctrl}}$ imposes on the specific geometry of the superposition created by $\mathbf{U}_{\text{prep}}$.

3.4 The Holosymmetric Path Scattering Model

3.4.1 Symmetric Path Scattering Model

Definition 3.14 (Symmetric Path Scattering Holosymmetric Operator)**.** Let $H_c \in \text{SU}(2)$ denote the Hadamard gate acting on the control register. Define the controlled evolution operator:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

and the Hadamard recombination gate:

$$\mathbf{U}_{\text{Had}} := H_c \otimes I_{\text{RR}}.$$

Then the *symmetric path scattering holosymmetric operator* is defined by the composition:

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{path-sym})} := \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}.} \tag{3.25}$$

3.4.2 Symmetric Path Scattering Model Double Slit Experiment

The Symmetric Path Scattering experiment models a recursive feedback loop where the system's evolution is modulated by an intermediate interference event. The procedure unfolds in three distinct acts.

Act I: Initial Evolution The process begins with the system in a simple basis state, $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$. The first controlled-unitary operator, $\mathbf{U}_{\text{ctrl}}$, is applied. This forces the system down a single, definite evolutionary path, producing the *evolved state*.

1. *Action:* $|\Psi_{\text{evolved}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{init}}\rangle$
2. *Resulting State:*
$$|\Psi_{\text{evolved}}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$

Act II: The Interference Event The Hadamard gate, $\mathbf{U}_{\text{Had}}$, now acts as a "scattering center." It takes the result of the first evolution and splits its control component into a coherent superposition, creating the *scattered state*.

1. *Action:* $|\Psi_{\text{scattered}}\rangle = \mathbf{U}_{\text{Had}}|\Psi_{\text{evolved}}\rangle$
2. *Resulting State:*
$$|\Psi_{\text{scattered}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$

Act III: Conditional Re-evolution The final $\mathbf{U}_{\text{ctrl}}$ operator acts on the newly created superposition. The system's subsequent evolution is now conditional on the outcome of the interference event in Act II.

1. *Action:* $|\Psi_{\text{final}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{scattered}}\rangle$
2. *Resulting State:*
$$\frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\right)^2 |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\right)|\Psi_{\text{RR}}\rangle\right)$$

This final state is a superposition of two distinct second-order histories, where the system's fate depends directly on the interplay between its initial evolution and the intermediate interference. This symmetric form uses identical logic for both branchings (same $\mathbf{U}_{\text{ctrl}}$), reflecting a reversible, time-symmetric holosymmetric recursion.

The Symmetric Path Scattering Model reveals a profound mechanism of *quantum recursive feedback*, fundamentally distinct from the Interferometer Model's parallel-path interference. Here, the universe doesn't simply explore multiple histories in parallel—it evolves along one path, encounters an interference event that creates quantum uncertainty about its own history, and then continues evolving in a superposition that depends on this self-induced uncertainty. The operator structure $\mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}$ encodes a temporal narrative: deterministic evolution leads to quantum scattering, which then conditions future evolution. This is not mere interference between alternatives, but a *dialectical process where the system's past determines how it will branch in the future.*

The three-act drama—Initial Evolution, Interference Event, and Conditional Re-evolution—models how quantum systems can exhibit *path-dependent memory through coherent feedback.* The final state reveals two remarkable histories: in one branch, the system evolves twice through the same parasymmetric assignment ($(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N})^2$), reinforcing its initial trajectory; in the other, it switches paths mid-evolution ($\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$), creating a hybrid history. This switching is not random but emerges from the quantum coherence introduced by the Hadamard scattering—the system literally interferes with its own evolutionary momentum, creating the possibility for self-modification.

Most profoundly, this model suggests that *the universe might possess a form of quantum reflexivity*—the ability to evolve, scatter off its own quantum state, and then continue evolving based on the interference pattern it creates with itself. Unlike the Interferometer Model's "which-path" detection, the Path Scattering Model implements "which-future" determination, where intermediate quantum events don't just reveal but actively sculpt subsequent evolution. The time-symmetric structure (using the same $\mathbf{U}_{\text{ctrl}}$ for both branchings) implies this process is fundamentally reversible, suggesting that just as the future can be conditioned by quantum interference in the past, the past might be retroactively influenced by future quantum scattering events—a truly radical vision of cosmic evolution as an ongoing dialogue between deterministic flow and quantum disruption.

3.4.3 Asymmetric Path Scattering Model

Definition 3.15 (Asymmetric Path Scattering Holosymmetric Operator)**.** Let $\mathbf{U}_{\text{ctrl}}^{\text{in}}$ and $\mathbf{U}_{\text{ctrl}}^{\text{out}}$ be two distinct controlled evolution operators acting on $\mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)}$, defined by:

$$\mathbf{U}_{\text{ctrl}}^{\text{in}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}},$$

$$\mathbf{U}_{\text{ctrl}}^{\text{out}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}}.$$

Let the Hadamard gate on the control register be:

$$\mathbf{U}_{\text{Had}} := H_c \otimes I_{\text{RR}}.$$

Then the *asymmetric path scattering holosymmetric operator* is given by:

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{path-asym})} := \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{\text{in}}.} \tag{3.26}$$

3.4.4 Asymmetric Path Scattering Model Double Slit Experiment

Act I: The "Input" Evolution The process begins with the system in the initial state $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$. The first operator applied is $\mathbf{U}_{\text{ctrl}}^{(\text{in})}$, which represents the "input" or "before" set of dynamical laws. This forces the system along a single, definite path, producing the *input-evolved state*.

- **Action:** $|\Psi_{\text{in-evolved}}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{in})}|\Psi_{\text{init}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{in-evolved}}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}|\Psi_{\text{RR}}\rangle$$

Act II: The "Transformative Interference Event" The Hadamard gate, $\mathbf{U}_{\text{Had}}$, acts as a transformative event. It takes the outcome of the initial evolution and splits its control component into a coherent superposition, representing the moment of quantum interference that will condition the future. This creates the *scattered state*.

- **Action:** $|\Psi_{\text{scattered}}\rangle = \mathbf{U}_{\text{Had}}|\Psi_{\text{in-evolved}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{scattered}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}|\Psi_{\text{RR}}\rangle$$

Act III: The "Output" Evolution Finally, the $\mathbf{U}_{\text{ctrl}}^{(\text{out})}$ operator is applied. This represents the "output" or "after" set of physical laws. It acts on the superposed state from Act II, and the system's final evolution is now governed by this new dynamical regime.

- **Action:** $|\Psi_{\text{final}}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{out})}|\Psi_{\text{scattered}}\rangle$
- **Resulting State:**

$$\frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}|\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}|\Psi_{\text{RR}}\rangle\right)$$

This final state represents a superposition of histories where the system evolved first under the "in" rules, was subjected to a quantum superposition, and then continued its evolution under the new "out" rules. This allows modeling of feedback structures where the interference outcome conditions the subsequent evolution, possibly representing environmental decoherence, observer choice, or cosmogenic selection mechanisms.

The Asymmetric Path Scattering Model reveals a *fundamentally irreversible quantum process* where the laws of physics themselves can undergo transformation through interference

events. Unlike the symmetric model's reversible feedback loop, the operator structure $\mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{\text{in}}$ encodes a temporal arrow: the universe evolves under one set of laws ("in"), encounters a transformative quantum event, then continues under potentially different laws ("out"). This models scenarios where *quantum interference doesn't just redirect evolution within fixed laws, but actually changes the laws themselves*—a mechanism for cosmological phase transitions, emergent complexity, or even observer-induced modifications to physical reality.

The three-act structure—Input Evolution, Transformative Interference Event, Output Evolution—captures how *singular quantum moments can serve as bridges between different physical regimes*. The final state shows the system in superposition between two histories: both branches initially evolved identically under the "in" laws, but after the Hadamard scattering, they diverge under different "out" assignments. The critical insight is that while both branches share the same past ($\hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}$), they experience different futures ($\hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}}$ vs $\hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}}$). This asymmetry between shared history and divergent destiny models how *quantum events can act as cosmic watersheds*, after which the universe's evolutionary rules themselves bifurcate, thereby creating a "divergent destiny" from a "shared history". The asymmetry between the "in" and "out" states ('$\mathbf{U}_{\text{ctrl}}^{(\text{in})} \neq \mathbf{U}_{\text{ctrl}}^{(\text{out})}$') breaks the time-reversal symmetry of the process, introducing a powerful "arrow of complexity" that is the hallmark of a truly evolving, learning universe.

Most profoundly, this framework suggests that *the universe might undergo discrete transformative events that reconfigure its own operating system.* These could manifest as cosmological epoch transitions (inflation to radiation domination), symmetry-breaking events (electroweak phase transition), or even measurement-induced law selection (anthropic observer effects). The asymmetric structure implies these transformations are irreversible—once the universe passes through such a quantum gateway, there's no returning to the previous regime. This positions quantum interference not just as a phenomenon within physics, but as the mechanism by which physics itself evolves, suggesting that our current laws might be just one branch of a vast superposition of possible physical regimes, selected through a sequence of transformative interference events stretching back to the cosmos's quantum origin.

3.5 The Recursive Expansion of the Path Scattering Model

3.5.1 Recursive Component Expansion: Symmetric Path Scattering

We consider the composite operator:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} := \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}},$$

where:

- The controlled evolution operator is given by:

$$\mathbf{U}_{\text{ctrl}} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G},$$

- The Hadamard operator acting on the control system is:

$$\mathbf{U}_{\text{Had}} := H_c \otimes I_{\text{RR}}, \quad \text{where} \quad H_c = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}.$$

Let us introduce shorthand:

$$U_A := \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}, \qquad U_B := \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}.$$

Then the operator becomes:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \begin{pmatrix} U_A & 0 \\ 0 & U_B \end{pmatrix} \cdot \left(\frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \right) \cdot \begin{pmatrix} U_A & 0 \\ 0 & U_B \end{pmatrix}.$$

Carrying out the matrix multiplication yields:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \frac{1}{\sqrt{2}} \begin{pmatrix} U_A^2 & U_A U_B \\ U_B U_A & -U_B^2 \end{pmatrix}.$$

We may then express this operator in control-basis decomposed form:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \sum_{i,j \in \{0,1\}} |\mathbf{i}\rangle_c \langle \mathbf{j}|_c \otimes \mathcal{S}_{ij}^{(\text{sym})},$$

where each matrix element $\mathcal{S}_{ij}^{(\text{sym})} \in \mathcal{U}(\mathcal{H}_{\text{RR}}^{(2n)})$ represents a distinct second-order scattering channel induced by the holosymmetric branching–interference–rebranching sequence.

$$\mathcal{S}_{00}^{(\text{sym})} = \frac{1}{\sqrt{2}} U_A^2 = \frac{1}{\sqrt{2}} \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} \right)^2 \tag{3.27}$$

$$\mathcal{S}_{01}^{(\text{sym})} = \frac{1}{\sqrt{2}} U_A U_B = \frac{1}{\sqrt{2}} \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} \, \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right) \tag{3.28}$$

$$\mathcal{S}_{10}^{(\text{sym})} = \frac{1}{\sqrt{2}} U_B U_A = \frac{1}{\sqrt{2}} \left(\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} \right) \tag{3.29}$$

$$\mathcal{S}_{11}^{(\text{sym})} = -\frac{1}{\sqrt{2}} U_B^2 = -\frac{1}{\sqrt{2}} \left(\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \right)^2 \tag{3.30}$$

Interpretation. These four components represent all second-order coherent transitions between the symmetric control basis states $|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c$, capturing the recursive structure of holosymmetric evolution across double-branch compositions. In particular:

- $\mathcal{S}_{00}^{(\text{sym})}$ corresponds to the constructive–constructive amplitude,
- $\mathcal{S}_{11}^{(\text{sym})}$ reflects a destructive–destructive feedback mode,
- The off-diagonal terms $\mathcal{S}_{01}^{(\text{sym})}, \mathcal{S}_{10}^{(\text{sym})}$ express interference transitions across distinct modal evolutions.

This decomposition enables experimental or simulation-based access to the full second-order dynamics of the symmetric holosymmetric interferometer.

3.5.2 Recursive Component Expansion: Asymmetric Path Scattering

We now consider a generalized recursive structure in which distinct control-dependent operators are applied before and after the interference layer:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} := \mathbf{U}_{\text{ctrl}}^{(\text{out})} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{(\text{in})},$$

where the "in" and "out" operators represent different sets of evolutionary rules:

- The input-controlled evolution is:

$$\mathbf{U}_{\text{ctrl}}^{(\text{in})} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}},$$

- The output-controlled evolution is:

$$\mathbf{U}_{\text{ctrl}}^{(\text{out})} := |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}},$$

and the Hadamard gate $\mathbf{U}_{\text{Had}}$ remains as previously defined.

We expand the composite operator $\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})}$ over the control basis:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} = \sum_{i,j\in\{0,1\}} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \mathcal{S}_{ij}^{(\text{asym})},$$

where the explicit matrix multiplication yields the following operator-valued matrix elements:

$$\boxed{\begin{aligned}
\mathcal{S}_{00}^{(\text{asym})} &= \frac{1}{\sqrt{2}}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}\right) && (3.31)\\
\mathcal{S}_{01}^{(\text{asym})} &= \frac{1}{\sqrt{2}}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}}\right) && (3.32)\\
\mathcal{S}_{10}^{(\text{asym})} &= \frac{1}{\sqrt{2}}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}\right) && (3.33)\\
\mathcal{S}_{11}^{(\text{asym})} &= -\frac{1}{\sqrt{2}}\left(\hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}} \cdot \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}}\right) && (3.34)
\end{aligned}}$$

Interpretation. This construction captures the most general form of recursive holosymmetric evolution currently formulated. Each component $\mathcal{S}_{ij}^{(\text{asym})}$ now explicitly shows the sequence of operations: an "in" evolution followed by an "out" evolution, corresponding to a specific scattering channel. This allows for the theoretical probing of second-order holosymmetric dynamics in fully generalized asymmetric scattering scenarios, where the rules of evolution themselves may change as a result of the interference event.

3.6 Experiment for Recursive Path Scattering Model

3.6.1 The Recursive Symmetric Path Scattering Case

Beyond the simple measurement of interference, the holosymmetric framework provides tools to model how interference itself can influence subsequent evolution. The *Symmetric Path Scattering Model* moves beyond the static comparison of the Interferometer Model into the realm of *dynamical feedback*. It describes a process where an initial evolution is subjected to a quantum interference event, and the outcome of that interference then dictates the system's future evolution.

The process is governed by the composite operator:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} := \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}$$

This sequence is not a simple measurement but a story of evolution, scattering, and re-evolution.

Initial State of the System The experiment begins with a well-defined initial quantum configuration for the physical system being studied. This is described by the state vector $|\Psi_{\text{RR}}\rangle$.

- **Formal Definition:** $|\Psi_{\text{RR}}\rangle$ represents the *joint quantum state of the dual PQS registers* (Register A and Register B). It is a vector in the dual-register Hilbert space $\mathcal{H}_{\text{RR}}^{(2n)} = \mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}$. It describes the complete quantum configuration, including all internal modes and entanglements, of the two n-PQS registers at the start of the experiment.
- **Role in the Experiment:** In this protocol, $|\Psi_{\text{RR}}\rangle$ serves as the *initial condition or "seed" state* that is subjected to the entire feedback process. The final outcome of the experiment is a direct consequence of how this specific initial configuration evolves under the recursive Path Scattering operator.

The Three Acts of Path Scattering The process begins with the composite system in the initial state $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$, where the control qubit selects the first evolutionary path.

Act I: Initial Evolution The first $\mathbf{U}_{\text{ctrl}}$ operator forces the system to evolve entirely along a single path, producing the *evolved state*.

- **Action:** $|\Psi_{\text{evolved}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{init}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{evolved}}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$

Act II: The Interference Event The Hadamard gate, $\mathbf{U}_{\text{Had}}$, now acts on the result of this first evolution. It functions as a "scattering center" that takes the evolved state and splits its control component into a coherent superposition, creating the *scattered state*.

- **Action:** $|\Psi_{\text{scattered}}\rangle = \mathbf{U}_{\text{Had}}|\Psi_{\text{evolved}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{scattered}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}|\Psi_{\text{RR}}\rangle$$

Act III: Conditional Re-evolution The final $\mathbf{U}_{\text{ctrl}}$ operator acts on the newly created superposition. The system's subsequent evolution is now conditional on the outcome of the scattering event in Act II.

- **Action:** $|\Psi_{\text{final}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{scattered}}\rangle$
- **Resulting State:**

$$\frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\right)^2 |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \left(\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\right)|\Psi_{\text{RR}}\rangle\right)$$

Interpretation of the Scattering Channels This process is compactly described by the operator matrix:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \frac{1}{\sqrt{2}}\begin{pmatrix} \left(\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\right)^2 & \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \\ \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} & -\left(\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}\right)^2 \end{pmatrix}$$

Each matrix element $\mathcal{S}_{ij}^{(\text{sym})}$ represents a distinct physical channel for this recursive process:

- $\mathcal{S}_{00}^{(\text{sym})}$: This is the amplitude for a system to start on Path A, scatter constructively, and continue on Path A. It represents a *self-reinforcing feedback loop*.
- $\mathcal{S}_{10}^{(\text{sym})}$: This is the amplitude for a system to start on Path A, scatter destructively (into the $|\mathbf{1}\rangle_c$ branch), and then be forced onto Path B. It represents a *history-altering interference*.
- The off-diagonal terms $\mathcal{S}_{01}^{(\text{sym})}$ and $\mathcal{S}_{10}^{(\text{sym})}$ capture the essence of the scattering: how interference can cause a "jump" between evolutionary trajectories.

This model describes a universe that can react to its own quantum state. It is a framework for *dynamics conditioned by interference*, a profound departure from the simple comparison of fixed histories offered by the Interferometer Model.

The Recursive Symmetric Path Scattering Model transforms the double-slit experiment from a passive measurement into an *active feedback mechanism* where quantum interference directly sculpts future evolution. Unlike the Interferometer Model's static comparison of parallel histories, this framework implements a temporal narrative where the universe

evolves deterministically along one path, encounters a quantum scattering event that creates superposition, and then continues evolving in a way that depends on the interference pattern it generated with itself. The matrix elements reveal distinct feedback channels: the diagonal terms $\mathcal{S}_{00}$ and $\mathcal{S}_{11}$ represent self-reinforcing loops where the system doubles down on its initial trajectory, while the off-diagonal terms $\mathcal{S}_{01}$ and $\mathcal{S}_{10}$ capture the profound possibility of *history-altering interference*—where quantum scattering can cause the universe to jump between evolutionary trajectories mid-flight.

This model presents a universe with *quantum reflexivity*, one that can sense and respond to its own quantum state via interference-mediated feedback. The three-act structure—Initial Evolution, Interference Event, Conditional Re-evolution—reveals cosmic evolution to be a continuous dialogue between deterministic flow and quantum disruption, supplanting the notion of a simple linear unfolding. Each interference event acts as a decision point where the universe's future is reshaped by the quantum coherence of its immediate past. In this light, quantum mechanics is re-envisioned as a theory of *adaptive evolution* that transcends its traditional role as a theory of measurement; reality continuously updates its own operating system through recursive cycles of evolution, self-interference, and path selection in a process analogous to a cosmic double-slit experiment, where the particle, having passed through one slit, can quantum-mechanically influence which slit it will traverse in the next iteration.

3.6.2 The Recursive Asymmetric Path Scattering Case

We now consider a generalized recursive structure that allows for the ultimate level of dynamical freedom: the evolutionary rules themselves may change as a result of an interference event. This is modeled by the *Asymmetric Path Scattering Operator*, where distinct control-dependent operators are applied before and after the central interference layer:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} := \mathbf{U}_{\text{ctrl}}^{(\text{out})} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{(\text{in})}$$

The Asymmetric Three-Act Process

This operator sequence describes a directed, potentially irreversible process of history-dependent evolution.

Act I: The "Input" Evolution The process begins with the system in the initial state $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$. The first operator applied is $\mathbf{U}_{\text{ctrl}}^{(\text{in})}$, which represents the "input" or "before" set of dynamical laws. This forces the system along a single, definite path according to these initial rules, producing the *input-evolved state*.

- **Action:** $|\Psi_{\text{evolved}}^{(\text{in})}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{in})}|\Psi_{\text{init}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{evolved}}^{(\text{in})}\rangle = |\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}}|\Psi_{\text{RR}}\rangle$$

Act II: The "Transformative Interference Event" The Hadamard gate, $\mathbf{U}_{\text{Had}}$, acts as a transformative event. It takes the outcome of the initial evolution and splits it into a coherent superposition, creating the *scattered state*.

- **Action:** $|\Psi_{\text{scattered}}\rangle = \mathbf{U}_{\text{Had}}|\Psi^{(\text{in})}_{\text{evolved}}\rangle$
- **Resulting State:**

$$|\Psi_{\text{scattered}}\rangle = \frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c + |\mathbf{1}\rangle_c\right) \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} |\Psi_{\text{RR}}\rangle$$

Act III: The "Output" Evolution Finally, the $\mathbf{U}^{(\text{out})}_{\text{ctrl}}$ operator is applied. This represents the "output" or "after" set of physical laws. It acts on the superposed state from Act II, and the system's final evolution is now governed by this new dynamical regime.

- **Action:** $|\Psi_{\text{final}}\rangle = \mathbf{U}^{(\text{out})}_{\text{ctrl}}|\Psi_{\text{scattered}}\rangle$
- **Resulting State:**

$$\frac{1}{\sqrt{2}}\left(|\mathbf{0}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} |\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}}\, \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} |\Psi_{\text{RR}}\rangle\right)$$

Interpretation of the Asymmetric Scattering Channels

The operator matrix for this process reveals the intricate dynamics of this transformation:

$$\mathbf{U}^{(\text{scatter,asym})}_{\text{holo}} = \frac{1}{\sqrt{2}} \begin{pmatrix} \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} & \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{out}} B_N^{\text{out}}} \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}} \\ \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}} \hat{\mathbf{U}}_{\text{RR}}^{A_G^{\text{in}} B_N^{\text{in}}} & -\hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{out}} B_G^{\text{out}}} \hat{\mathbf{U}}_{\text{RR}}^{A_N^{\text{in}} B_G^{\text{in}}} \end{pmatrix}$$

Each component $\mathcal{S}^{(\text{asym})}_{ij}$ now represents a complete history of transformation:

- $\mathcal{S}^{(\text{asym})}_{00}$: This is the amplitude for a system to start on input Path 1, scatter constructively, and then evolve under the new output Path 1. It describes a transition between two different "laws of physics" within the same constructive channel.
- $\mathcal{S}^{(\text{asym})}_{10}$: This is the amplitude to start on input Path 1, scatter destructively, and then be forced to evolve under the new output Path 2. It represents a process where the interference event triggers a fundamental shift in the system's dynamical rules.

The Asymmetric Path Scattering Model represents the ultimate expression of quantum cosmological evolution: *a universe whose fundamental laws are not eternal edicts but living, adaptive structures that transform through quantum interference.* This framework transcends the conventional notion of physics as the discovery of immutable laws, instead revealing a cosmos that literally *learns* from its own quantum history. Each transformative interference event—marked by the transition from "input" to "output" control operators—represents a moment where the universe samples its own quantum state and updates its operating system accordingly. The mathematical structure $\mathbf{U}^{(\text{out})}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}^{(\text{in})}_{\text{ctrl}}$ encodes a profound asymmetry:

the universe that emerges from the interference event operates under different rules than the one that entered it.

This "learning universe" paradigm offers revolutionary insights into cosmological evolution and quantum measurement. *Cosmological phase transitions* become not mere rearrangements of matter but fundamental rewrites of physical law—the early universe's inflation-to-radiation transition might represent such a transformative interference event where the "output" physics bears little resemblance to the "input". Similarly, *quantum measurement* transforms from a mysterious collapse to a natural consequence of this framework: observation creates an interference event that doesn't just reveal the system's state but fundamentally alters how it will evolve thereafter. Most profoundly, this suggests the universe possesses a form of *quantum memory and adaptability*—its future dynamics are continuously sculpted by the accumulated interference patterns of its past, creating a cosmos that grows ever more complex and refined through recursive cycles of evolution, self-measurement, and law transformation. We inhabit not a clockwork universe grinding through predetermined motions, but a *quantum learning system* that discovers and refines its own principles through the eternal dance of interference and adaptation.

3.7 Commutator Lensing of the Path Scattering Model

3.7.1 Commutator Lensing of the Symmetric Path Scattering Model

Definition 3.16 (Commutator Lensing of the Symmetric Path Scattering Model)**.** Let $\mathbf{U}_{\text{ctrl}}$ be the controlled path operator and $\mathbf{U}_{\text{Had}} = (H_c \otimes I_{\text{RR}})$ be the Hadamard operator. Define the *symmetric commutator lensing of the path scattering operator* as:

$$\mathbf{U}_{\text{holo}}^{(\text{psym-com})} := \mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}].$$

Interpretation:

- The evolution begins with conditional branching via $\mathbf{U}_{\text{ctrl}}$, followed by interference via $\mathbf{U}_{\text{Had}}$, and concludes with a second branching.
- The commutator $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$ quantifies the deviation from symmetric recombination and identifies modal scattering curvature induced by recursive interference.
- The outer $\mathbf{U}_{\text{ctrl}}$ recouples the branches after interference has reshaped them.

This captures the structural asymmetry introduced by modal recursion under fixed control logic.

3.7.2 Commutator Lensing of the Asymmetric Path Scattering

Definition 3.17 (Commutator Lensing of the Asymmetric Path Scattering Model)**.** Let $\mathbf{U}_{\text{ctrl}}^{\text{in}} = (C_c^{\text{in}} \otimes I_{\text{RR}})$, $\mathbf{U}_{\text{ctrl}}^{\text{out}} = (C_c^{\text{out}} \otimes I_{\text{RR}})$, and let $\mathbf{U}_{\text{Had}} = (H_c \otimes I_{\text{RR}})$. Define the *asymmetric commutator lensing of the path scattering operator* as:

$$\mathbf{U}_{\text{holo}}^{(\text{pasym-com})} := \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}].$$

Interpretation:

- This operator enacts initial conditional branching using $\mathbf{U}_{\text{ctrl}}^{\text{in}}$,
- Interference occurs via $\mathbf{U}_{\text{Had}}$, and
- Final conditional transformation $\mathbf{U}_{\text{ctrl}}^{\text{out}}$ post-selects modal pathways based on the interference outcome.

The commutator $[\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}]$ again reveals how interference reshapes the logical space of modal evolution, and how distinct forms of path logic affect this reshaping.

Summary of Commutator Lensing of Path Scattering The *commutator formalism* for the Path Scattering Model comes in two principal variants, each characterized by a distinct operator structure and interpretive role.

In the *symmetric case*, the holosymmetric evolution is governed by the operator

$$\mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}],$$

which applies initial branching, captures the curvature induced by interference through the commutator, and reapplies the same control logic. This construction probes the deformation of modal structure induced by symmetric feedback recursion.

In the *asymmetric case*, the evolution is governed by the operator

$$\mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}],$$

where distinct pre- and post-interference control logics are employed. This formulation models non-identical modal rebranching conditioned on the intermediate interference outcome, revealing how different control strategies sculpt recursive structure. Both forms operationalize holosymmetry as an algebra of commutators, offering a direct measure of modal incompatibility and recursive curvature within the interference-driven quantum evolution of dual PQS configurations.

3.7.3 The Commutator Lensing Double-Slit Experiments

The Commutator formalism provides a profound theoretical lens, reframing interference as a direct consequence of the non-commutativity of quantum operations. The following protocols describe how one would operationally measure the "dynamical twist" isolated by these commutators. Each experiment is itself a meta-interferometer, designed to compare two distinct sequences of operations.

Probing the Symmetric Path Scattering Commutator

To measure the physical effect of the operator $\mathbf{U}_{\text{holo}}^{(\text{psym-com})} = \mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$, which describes how an interference event is filtered through a final evolutionary stage.

The Experimental Protocol This is a three-stage, comparative experiment.

1. **Stage 1: Create the two parallel histories.**

- *Arm A (Evolve then Superpose):* Prepare the state $|\Psi_{\text{E then S}}\rangle = \mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}}|\Psi_{\text{init}}\rangle$.
- *Arm B (Superpose then Evolve):* Prepare the state $|\Psi_{\text{S then E}}\rangle = \mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{Had}}|\Psi_{\text{init}}\rangle$.

2. **Stage 2: Isolate the "Dynamical Twist".** The physical difference between the two arms is the action of the commutator. We can formally define the "commutator state" as their difference:

$$|\Psi_{\text{commutator}}\rangle := |\Psi_{\text{S then E}}\rangle - |\Psi_{\text{E then S}}\rangle = [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]|\Psi_{\text{init}}\rangle$$

3. **Stage 3: Apply Final Evolution and Measure.** The full Path Scattering operator requires a final application of $\mathbf{U}_{\text{ctrl}}$. We apply this to the commutator state:

$$|\Psi_{\text{final}}\rangle = \mathbf{U}_{\text{ctrl}}|\Psi_{\text{commutator}}\rangle = \mathbf{U}_{\text{ctrl}}[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]|\Psi_{\text{init}}\rangle$$

   A measurement of an observable $\hat{O}$ on this final state would reveal the physical consequences of this full process.

Interpretation This experiment measures how the fundamental "twist" between superposition and evolution is itself transformed by a subsequent evolution.

Probing the Asymmetric Path Scattering Commutator

To measure the effect of the most general operator, $\mathbf{U}_{\text{holo}}^{(\text{pasym-com})} = \mathbf{U}_{\text{ctrl}}^{(\text{out})} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{(\text{in})}]$, which models a change in physical law after an interference event.

The Experimental Protocol

1. **Stage 1: Create two parallel histories based on the "in" laws.**

   - *Arm A:* $|\Psi_{\text{E then S}}\rangle = \mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}}^{(\text{in})}|\Psi_{\text{init}}\rangle$
   - *Arm B:* $|\Psi_{\text{S then E}}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{in})}\mathbf{U}_{\text{Had}}|\Psi_{\text{init}}\rangle$

2. **Stage 2: Isolate the "Input Twist".** Define the "input commutator state":

$$|\Psi_{\text{commutator-in}}\rangle := |\Psi_{\text{S then E}}\rangle - |\Psi_{\text{E then S}}\rangle = [\mathbf{U}_{\text{ctrl}}^{(\text{in})}, \mathbf{U}_{\text{Had}}]|\Psi_{\text{init}}\rangle$$

3. **Stage 3: Apply "Output" Laws and Measure.** Apply the new, "output" evolution operator to the result of the initial interference:

$$|\Psi_{\text{final}}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{out})}|\Psi_{\text{commutator-in}}\rangle = \mathbf{U}_{\text{ctrl}}^{(\text{out})}[\mathbf{U}_{\text{ctrl}}^{(\text{in})}, \mathbf{U}_{\text{Had}}]|\Psi_{\text{init}}\rangle$$

The Commutator Formalism transforms abstract algebraic concepts into measurable physical quantities by constructing *meta-interferometers* that probe the fundamental non-commutativity of quantum operations. Rather than measuring interference between states, these experiments measure interference between *sequences of operations*—revealing what the framework calls the "dynamical twist" encoded in commutators like $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$. The experimental protocol is elegantly comparative: create two parallel histories by applying the same operations in different orders (evolve-then-superpose vs. superpose-then-evolve), subtract them to isolate the pure commutator state, then apply a final transformation to make this abstract quantity observable. This commutator state $|\Psi_{\text{commutator}}\rangle$ represents the irreducible quantum tension between different operational sequences—a physical manifestation of the fact that in quantum mechanics, the order of operations fundamentally matters.

The symmetric protocol measures how this fundamental twist is itself transformed by subsequent evolution, revealing how *interference begets interference* in recursive cycles. But the asymmetric protocol achieves something even more profound: it operationalizes the concept of a "learning universe" by measuring how the algebraic tension created under one set of laws ($\mathbf{U}_{\text{ctrl}}^{(\text{in})}$) is projected and transformed by an entirely different set ($\mathbf{U}_{\text{ctrl}}^{(\text{out})}$). This provides the experimental signature for cosmological phase transitions and law evolution—the output measurement reveals how the "memory" of non-commutativity under old physics manifests under new physics.

These meta-interferometric protocols represent a new class of quantum experiments that transcend the probing of states or processes to investigate the *algebraic structure of quantum mechanics itself*. By making commutators—traditionally abstract mathematical objects—into measurable quantities, the framework suggests that the universe's deepest properties lie in its operational grammar, rather than its content: the patterns of non-commutativity that govern how different quantum operations fail to commute. This elevates interference from a phenomenon occurring within fixed laws to the very mechanism by which the laws themselves are structured, measured, and potentially transformed—turning the double-slit experiment into a probe of the universe's fundamental algebraic architecture.

3.8 Definition: Holosymmetry (Holothesis)

Definition 3.18 (Holosymmetry (Holothesis): Formal Definition)**.** Fix two disjoint n-PQS registers and a control qubit as in Definitions 2.101 and 2.102:

$$\mathcal{H}_{\text{Holo}} := \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)} = \mathcal{H}_c \otimes \left(\mathcal{H}_{\text{PQS}}^{(n,A)} \otimes \mathcal{H}_{\text{PQS}}^{(n,B)}\right), \qquad \dim \mathcal{H}_{\text{Holo}} = 2^{4n+1}.$$

Let $U_G^{(\odot)}$ and $U_N^{(\odot)}$ be the global–coupled and decoupled parasymmetric evolutions on a single register (Definitions 2.66 and 2.85), and let the *lifted path unitaries* on $\mathcal{H}_{\text{RR}}^{(2n)}$ be

$$\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} := U_G^{(A)} U_N^{(B)}, \qquad \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} := U_N^{(A)} U_G^{(B)} \quad \text{(Definitions 2.103 and 2.108)}.$$

(H1) Holosymmetric unitary (branching form). A *holosymmetric realization* is any unitary $\mathbf{U}_{\text{holo}} \in \mathcal{U}(\mathcal{H}_{\text{Holo}})$ that is control-block linear with respect to the computational basis of $\mathcal{H}_c$,

up to local control pre/post rotations: there exist unitaries $\mathbf{U}_{\text{prep}}, \mathbf{U}_{\text{read}} \in \mathcal{U}(\mathcal{H}_c)$ such that

$$\mathbf{U}_{\text{holo}} = (\mathbf{U}_{\text{read}} \otimes I_{\text{RR}}^{(2n)}) \Big(|\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_G B_N} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\text{RR}}^{A_N B_G} \Big) (\mathbf{U}_{\text{prep}} \otimes I_{\text{RR}}^{(2n)}). \tag{3.35}$$

Canonical choices recover the standard models:

$$\mathbf{U}_{\text{ctrl}} \ (\mathbf{U}_{\text{prep}} = \mathbf{U}_{\text{read}} = I_c), \qquad \mathbf{U}_{\text{Had}} \ (\mathbf{U}_{\text{prep}} = \mathbf{U}_{\text{read}} = H_c),$$

and their commutator-lensing variants (Definitions 2.114 and 2.119).

(H2) Holosymmetric effect (valuation link). For control preparation $|\mathbf{a}\rangle_c \in \mathcal{H}_c$ and readout $|\mathbf{b}\rangle_c \in \mathcal{H}_c$, the *holosymmetric effect* on the dual-register space is the positive operator

$$E_{\text{Holo}}^{(\mathbf{a}\twoheadrightarrow\mathbf{b})} := \langle \mathbf{b}|_c \, \mathbf{U}_{\text{holo}} \Big(|\mathbf{a}\rangle\langle\mathbf{a}|_c \otimes I_{\text{RR}}^{(2n)} \Big) \mathbf{U}_{\text{holo}}^{\dagger} \, |\mathbf{b}\rangle_c \ \in \ \mathcal{B}^{+}\Big(\mathcal{H}_{\text{RR}}^{(2n)}\Big). \tag{3.36}$$

Given a register state ρ_{RR}, the *Holothesis valuation* is the Born propensity $v_{\text{Holothesis}}(\rho_{\text{RR}}) = \text{Tr}\Big(E_{\text{Holo}}^{(\mathbf{a}\twoheadrightarrow\mathbf{b})} \, \rho_{\text{RR}}\Big)$ (Definition 1.18).

(H3) Ontological identification. Holosymmetry is the fourth corner (Holothesis) of the Fourfold Dialectic Algebra (Definition 1.16). Its ontological label $\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{1}}}^{\mathring{\mathbf{0}}}$ denotes the meta-operator that coherently compares and interferes *entire* evolutionary histories —the two path unitaries above—rather than individual states.

(H4) Equivalences. Holosymmetric realizations related by (i) control-basis changes $\mathbf{U}_{\text{prep}}, \mathbf{U}_{\text{read}} \in \mathcal{U}(\mathcal{H}_c)$, (ii) a global register swap $A \leftrightarrow B$, or (iii) common conjugation $W \in \mathcal{U}(\mathcal{H}_{\text{RR}}^{(2n)})$ (i.e. $\hat{\mathbf{U}}_{A,B} \mapsto W \, \hat{\mathbf{U}}_{A,B} \, W^{\dagger}$), are *physically equivalent*: they define the same family of effects $\{E_{\text{Holo}}^{(\mathbf{a}\twoheadrightarrow\mathbf{b})}\}$ and valuations.
In particular, the "lensing'' presentations (sym-com, asym-com, psym-com, pasym-com) are obtained by such control pre/post rotations and thus lie in the same equivalence class. Writing the controlled form as

$$\mathbf{U}_{\text{ctrl}} \ = \ I_c \otimes U_+ \ + \ Z_c \otimes U_-, \qquad U_{\pm} := \tfrac{1}{2}\Big(\hat{\mathbf{U}}_A \pm \hat{\mathbf{U}}_B\Big),$$

(with Z_c the Pauli-Z on $\mathcal{H}_c$), any control rotation R satisfies

$$[R, \mathbf{U}_{\text{ctrl}}] \ = \ [R, Z_c] \otimes U_-,$$

so the commutator filters out the sum U_+ and isolates the difference $U_- = \frac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$ without introducing new resources; conjugation by $\mathbf{U}_{\text{read}}^{\dagger}$ simply undoes the chosen control basis. Thus the lensing forms are reparametrizations of (3.35) under the (H4) moves (Definition 3.18).

In this sense, *Holosymmetry* is the unitary-equivalence class of triples

$$\Big(\mathcal{H}_{\text{Holo}}, \ \mathbf{U}_{\text{holo}}, \ \{E_{\text{Holo}}^{(\mathbf{a}\twoheadrightarrow\mathbf{b})}\} \Big)$$

that satisfy (3.35)–(3.36). It *operationalizes* the Holothesis: a meta-level synthesis testing the similarity/dissonance between alternative parasymmetric evolutions via controlled interference.

Notes.

(i) The three model "presentations''—interferometric, path-scattering, and commutator-lensing—are recovered by specific choices of $\mathbf{U}_{\text{prep}}$, $\mathbf{U}_{\text{read}}$ and by expanding (3.35) in the $\{\,|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\,\}$ or $\{\,|+\rangle_c, |-\rangle_c\,\}$ bases; see Definitions 2.114 and 2.119 and the lensing definitions therein.

(ii) In the emergent/GNS layer, all valuations lift to standard expectations on $\mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}} = \mathcal{H}_{\text{em}}$ via $\pi_{\overset{\circ}{\mathbf{\Psi}}}$ (cf. Definition 1.34).

Intuitive reading. Holosymmetry asks a meta-question: not "which state is realized?" but "how similar or dissonant are *entire* evolutionary histories?" The normal form (3.35) makes this concrete: the control register coherently addresses two global evolutions on the dual PQS registers, $\hat{\mathbf{U}}_{\text{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\text{RR}}^{A_N B_G}$, and then recombines them. What the experiment reads out is not a yes/no judgment but a *propensity*, the Born valuation of the holosymmetric effect $E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ in (3.36). Large values signal "constructive agreement'' of the histories under the chosen preparation/readout; small values highlight "dissonance'' (destructive interference). This realizes the Holothesis corner of the Fourfold Dialectic Algebra (Definition 1.16) at the level of *processes* rather than states.

Operational picture. Think of $E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ as a matched filter on dynamics: by selecting $(\mathbf{a}, \mathbf{b})$ we decide which relational feature of the two histories to test. Choosing the computational basis emphasizes the "same-port'' vs. "opposite-port'' outcomes (synthesis vs. dissonance), while the $\{|+\rangle_c, |-\rangle_c\}$ basis reveals complementary structure, recovering the interferometer, path-scattering, and lensing presentations via the settings of $\mathbf{U}_{\text{prep}}$ and $\mathbf{U}_{\text{read}}$ (cf. (3.35) and Notes (i)). Crucially, Holosymmetry is an *equivalence class* of such realizations: local rotations of the control, common conjugations on the registers, or swapping the labels $A \leftrightarrow B$ leave the family of effects—and thus all valuations—unchanged (see Definition 3.18).

Bridge to the emergent layer. All holosymmetric valuations are ordinary quantum expectations once lifted to the emergent/GNS layer: $\omega^{\overset{\circ}{\mathbf{\Psi}}}(E) = \langle \Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}} | \pi_{\overset{\circ}{\mathbf{\Psi}}}(E) | \Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}} \rangle$ and, for any preparation ρ on $\mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}} = \mathcal{H}_{\text{em}}$, $v(\rho; E) = \text{Tr}(\rho\, \pi_{\overset{\circ}{\mathbf{\Psi}}}(E))$ (Definitions 1.18 and 1.34). Thus the compact definition packages an ontological claim (Holothesis as the fourth corner), an operational mechanism (controlled comparison of histories), and a mathematical realization (effects and Born valuations) into a single pipeline from logic to laboratory readout—without invoking indefinite causal order. If one ever wished to superpose *orders* rather than *which history*, that would require an explicit higher-order extension; Holosymmetry here concerns coherent comparison of fixed-order global evolutions.

3.8.1 Holosymmetry (Holothesis): Summary of Quantum Construction

We now summarize the quantum construction of *Holosymmetry*, the Holothesis in the Fourfold Dialectic Algebra of Symmetry as follows: **Holosymmetry** is the fourth and highest principle in the *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16). As the *Holothesis*, it governs the coherent superposition and interference of entire evolutionary histories, placing dynamical laws themselves into quantum superposition.

1. Ontological Architecture

The holosymmetric operator

$$\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{0}}\mathring{\mathbf{1}}}$$

is characterized by three fundamental ontological modes:

(i) *Symmetry* ($\mathring{\mathbf{0}}$): identity and coherence (Thesis)

(ii) *Antisymmetry* ($\mathring{\mathbf{1}}$): difference and negation (Antithesis)

(iii) *Parasymmetry* ($\mathring{\mathbf{0}} + \mathring{\mathbf{1}}$): dialectical synthesis of the dual modes

Unlike the lower modes, Holosymmetry operates at a meta-level where these constituents are not external elements but integral to its logical structure. It unifies the complete dialectical framework within a single transcendent principle.

2. Operational Functionality: Synthesis of Dynamical Processes

Holosymmetry enables a **holopositional synthesis** of distinct modal trajectories. This synthesis is not a single process but is realized through three complementary operational modes, each designed to probe a different aspect of the relationship between universal histories. Symbolically, we write:

$$\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{0}}\mathring{\mathbf{1}}} \doteq \mathfrak{S}\left[\mathring{\mathbf{0}},\ \mathring{\mathbf{1}},\ \mathring{\mathbf{0}}+\mathring{\mathbf{1}};\ \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\right]$$

where the synthesis functional $\mathfrak{S}[\cdot]$ now represents one of the following three distinct functions:

1. *Interferometric Comparison:* coherently superposes parallel evolutionary paths to measure their relational difference, acting as a cosmic interferometer.

2. *Recursive Scattering:* models dynamical feedback, where the outcome of an interference event transforms the subsequent evolutionary laws of the system.

3. *Algebraic Lensing:* isolates the non-commutative "twist" between quantum operations as the fundamental algebraic source of all interference phenomena.

3. Mathematical Realization

Holosymmetry is implemented through unitary operators acting on the composite Hilbert space:

$$\mathbf{U}_{\mathrm{holo}} \in \mathcal{U}\left(\mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}\right)$$

where:

- $\mathcal{H}_c \cong \mathbb{C}^2$ is the control register space
- $\mathcal{H}_{\mathrm{RR}}^{(2n)} = \bigotimes_{i=1}^{2n} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x_i})}$ is the dual PQS register space
- Each PQS modal space $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ encodes the complete fourfold dialectical structure

The total holosymmetric Hilbert space has dimension:

$$\dim(\mathcal{H}_{\text{Holo}}) = 2^{4n+1}$$

The holosymmetric operator decomposes as:

$$\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{i}}}^{\mathring{\mathbf{0}}} = \sum_{i,j\in\{0,1\}} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \Lambda_{ij}^{(\text{model})}$$

where the three canonical models are:

1. **Interferometric Model:**

$$\mathbf{U}_{\text{holo}}^{(\text{interferometer})} = \mathbf{U}_{\text{read}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{prep}}$$

   Enables full tomographic control over superposed evolutionary paths.

2. **Path Scattering Model:**

$$\mathbf{U}_{\text{holo}}^{(\text{scatter})} = \mathbf{U}_{\text{ctrl}}^{(\text{out})} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{(\text{in})}$$

   Captures irreversible dynamics and transitions between physical regimes.

3. **Commutator Lensing:** Isolates the algebraic source of quantum interference by examining:

   (a) *Symmetric Interferometer Lensing*: Probes the fundamental twist in a balanced system.

$$\mathbf{U}_{\text{holo}}^{(\text{sym-com})} := [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}] \cdot \mathbf{U}_{\text{Had}}^{\dagger}$$

   (b) *Asymmetric Interferometer Lensing*: Probes how an arbitrary preparation is distorted by the evolution.

$$\mathbf{U}_{\text{holo}}^{(\text{asym-com})} := [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] \cdot \mathbf{U}_{\text{read}}^{\dagger}$$

   (c) *Symmetric Path Scattering Lensing*: Probes how the fundamental twist evolves under a feedback loop.

$$\mathbf{U}_{\text{holo}}^{(\text{psym-com})} := \mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$$

   (d) *Asymmetric Path Scattering Lensing*: Probes how the twist generated by "in" laws is transformed by "out" laws.

$$\mathbf{U}_{\text{holo}}^{(\text{pasym-com})} := \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}]$$

   Provides direct access to the non-commutative structure underlying quantum dynamics.

Valuation Link With control prepared in $|\mathbf{a}\rangle_c$ and read out in $|\mathbf{b}\rangle_c$, the Holothesis valuation is $v_{\text{Holothesis}}(\rho_{\text{RR}}) = \text{Tr}\Big(E^{(\mathbf{a}\to\mathbf{b})}_{\text{Holothesis}}\,\rho_{\text{RR}}\Big)$ as defined in Definition 1.18.

Let the operator $\hat{\mathbf{U}}_A$ describes a universal history where the PQSs in Register A evolve as a single, indivisible entangled system, while the PQSs in Register B evolve in a modular, separable fashion:

$$\hat{\mathbf{U}}_A \equiv \hat{\mathbf{U}}^{A_G B_N}_{\text{RR}} := \Big(U^{(\odot)}_G \otimes \mathbb{I}^{(B)}\Big) \cdot \Big(\mathbb{I}^{(A)} \otimes U^{(\odot)}_N\Big)$$

And let the operator $\hat{\mathbf{U}}_B$ describes the alternate universal history where the PQSs in Register B are fully entangled in their dynamics, while Register A evolves in a separable manner:

$$\hat{\mathbf{U}}_B \equiv \hat{\mathbf{U}}^{A_N B_G}_{\text{RR}} := \Big(U^{(\odot)}_N \otimes \mathbb{I}^{(B)}\Big) \cdot \Big(\mathbb{I}^{(A)} \otimes U^{(\odot)}_G\Big)$$

Then the holosymmetric operator expands in the following manner:

1. The Interferometer Model Expansion This model realizes Holosymmetry as a process of *Prepare* → *Evolve* → *Recombine* to probe the interference between universal histories.

(a) Symmetric Interferometer

$$\mathbf{U}^{(\text{sym})}_{\text{holo}} = \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{0}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{(\text{sym-int})} =& |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \Big[\tfrac{1}{2}(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)\Big] + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \Big[\tfrac{1}{2}(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)\Big] \\ &+ |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \Big[\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\Big] + |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \Big[\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\Big]\end{aligned}$$

1. *The* Λ_{00} *and* Λ_{11} *Components:* A Synthesis of Histories

   - *Mathematical Form*: $\Lambda_{00} = \Lambda_{11} = \frac{1}{2}(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)$.
   - *Detailed Interpretation*: These components represent the amplitude for a process where the control qubit's state *does not flip* (i.e., a process of type $0 \to 0$ or $1 \to 1$). In the interferometer analogy, this corresponds to a particle exiting through the "same port" it metaphorically entered. For this to happen, the quantum amplitudes of the two internal paths must add together, or interfere *constructively*.

     The operator sum $(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)$ is the precise mathematical expression of this constructive synthesis. It does not select one path or the other; rather, it produces a final state that is a coherent superposition of the outcomes of *both* evolutionary histories. This is why we identify its function with *Parasymmetry*, the dialectical principle of synthesis, now applied to entire dynamical processes.

2. *The* Λ_{01} *and* Λ_{10} *Components:* A Dissonance of Histories

- *Mathematical Form*: $\Lambda_{01} = \Lambda_{10} = \frac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$.
- *Detailed Interpretation*: These components represent the amplitude for a process where the control qubit's state *flips* (i.e., a transition from $0 \to 1$ or $1 \to 0$). In the interferometer analogy, this is equivalent to the particle switching paths and exiting through the "opposite port" It can only occur if the quantum amplitudes of the two paths interfere *destructively*, largely cancelling each other out to allow for a transition that is classically forbidden.

  The operator difference $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$ mathematically isolates this destructive dissonance. It computes the "difference" between the two universal histories. We therefore identify its function with *Anti-Parasymmetry*, the dialectical principle of dissonance or anti-synthesis.

In summary, the four matrix elements of the Symmetric Interferometer operator provide a complete description of the interference experiment. The diagonal terms quantify the degree of agreement or synthesis between the two histories, while the off-diagonal terms quantify their disagreement or dissonance.

(b) Asymmetric Interferometer

$$\mathbf{U}_{\text{holo}}^{(\text{asym})} = \mathbf{U}_{\text{read}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{prep}}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{0}}\mathring{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{\circ\,(\text{asym-int})} =& |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left[\gamma\alpha\hat{\mathbf{U}}_A - \delta^*\beta\hat{\mathbf{U}}_B\right] + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\delta\beta^*\hat{\mathbf{U}}_A + \gamma^*\alpha^*\hat{\mathbf{U}}_B\right] \\ &+ |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\gamma\beta^*\hat{\mathbf{U}}_A - \delta^*\alpha^*\hat{\mathbf{U}}_B\right] + |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[\delta\alpha\hat{\mathbf{U}}_A + \gamma^*\beta\hat{\mathbf{U}}_B\right]\end{aligned}$$

By comparing this to the universal form $\sum_{i,j} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \Lambda_{ij}$, we can directly identify the four operator-valued matrix elements.

1. *The Λ_{00} Component:*
$$\Lambda_{00}^{(\text{asym-int})} = \gamma\alpha\hat{\mathbf{U}}_A - \delta^*\beta\hat{\mathbf{U}}_B$$
2. *The Λ_{01} Component:*
$$\Lambda_{01}^{(\text{asym-int})} = -\gamma\beta^*\hat{\mathbf{U}}_A - \delta^*\alpha^*\hat{\mathbf{U}}_B$$
3. *The Λ_{10} Component:*
$$\Lambda_{10}^{(\text{asym-int})} = \delta\alpha\hat{\mathbf{U}}_A + \gamma^*\beta\hat{\mathbf{U}}_B$$
4. *The Λ_{11} Component:*
$$\Lambda_{11}^{(\text{asym-int})} = -\delta\beta^*\hat{\mathbf{U}}_A + \gamma^*\alpha^*\hat{\mathbf{U}}_B$$

1. The Role of Preparation (α, β) The preparation gate acts first, transforming the initial control state into an arbitrary superposition $\alpha|0\rangle_c + \beta|1\rangle_c$.

- α becomes the initial complex amplitude for the history that will evolve down *Path A* (governed by $\hat{\mathbf{U}}_A$).
- β becomes the initial complex amplitude for the history that will evolve down *Path B* (governed by $\hat{\mathbf{U}}_B$).

This is analogous to using a variable beam splitter in an optics experiment; we can control the intensity and relative phase of the two paths being compared.

2. The Role of Readout (γ, δ) The readout gate acts last, projecting the two evolved histories onto a new measurement basis before the final observation. For example, to be measured in the final state $|0\rangle_c$, a state receives a contribution of γ times its $|0\rangle_c$ component and $-\delta^*$ times its $|1\rangle_c$ component.

3. Detailed Interpretation of the Matrix Elements Each matrix element Λ_{ij} represents the total process operator for the $j \to i$ transition, combining the effects of preparation, evolution, and readout.

1. $\Lambda_{00}^{(asym\text{-}int)} = \gamma\alpha\hat{\mathbf{U}}_A - \delta^*\beta\hat{\mathbf{U}}_B$ This is the operator for the $0 \to 0$ process. It is a coherent sum of two amplitudes:

   - The amplitude for the Path A history ($\alpha\hat{\mathbf{U}}_A$) to be projected onto the final $|0\rangle_c$ state by the readout gate (a factor of γ).
   - The amplitude for the Path B history ($\beta\hat{\mathbf{U}}_B$) to be projected onto the final $|0\rangle_c$ state (a factor of $-\delta^*$).

   The final operator is the tunable interference pattern between these two weighted, evolved paths.

2. *The Other Components:* The remaining elements follow the same logic. For example, $\Lambda_{10} = \delta\alpha\hat{\mathbf{U}}_A + \gamma^*\beta\hat{\mathbf{U}}_B$ describes the process for a $0 \to 1$ flip, where the amplitudes from each path are projected onto the final $|1\rangle_c$ state.

In essence, each component is a *Tunable Synthesis/Dissonance Operator*. By choosing the four parameters, an experimenter can precisely control the interference, allowing them to isolate different aspects of the relationship between the two universal histories. This makes the asymmetric model a complete *tomographic tool* for mapping the relational structure of quantum dynamics.

2. The Path Scattering Model Expansion

(a) Symmetric Path Scattering

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{0}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{(\text{sym-scatter})} =& |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^2\right] + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^2\right] \\ &+ |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A\hat{\mathbf{U}}_B\right] + |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B\hat{\mathbf{U}}_A\right]\end{aligned}$$

Each matrix element Λ_{ij} is a *Transformative History Operator*. These components describes feedback as well as the fundamental change in the rules of evolution. The components are *Iterated and Hybrid History Operators*.

- The diagonal elements $(\Lambda_{00}, \Lambda_{11})$ represent *self-reinforcing feedback loops*, where a history's character is preserved through the interference event ($A \to A$ or $B \to B$).
- The off-diagonal elements $(\Lambda_{01}, \Lambda_{10})$ represent *path-switching feedback*, where the interference event causes a transition between the two types of evolutionary dynamics ($A \to B$ or $B \to A$).

Synthesis: A Universe in Dialogue with Itself Together, these four operators paint a picture of a universe that is in a constant dialogue with its own quantum state. The diagonal elements provide the stability and continuity of physical law, while the off-diagonal elements provide the potential for radical, revolutionary change. The interplay between these four channels dictates the entire cosmic history, from long periods of stable evolution to the singular moments of transformation that define its great epochs.

(b) Asymmetric Path Scattering

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} = \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{\text{in}}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{0}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{(\text{asym-scatter})} =& |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}\right] + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}\right] \\ &+ |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}\right] + |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}\right]\end{aligned}$$

By comparing the ontological expansion to the universal form $\sum_{i,j} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \Lambda_{ij}$, we can identify the explicit operator for each matrix element.

1. *The Λ_{00} Component:*

$$\Lambda_{00}^{(\text{asym-scatter})} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}$$

Interpretation: This represents the amplitude for a history that maintains its fundamental character (Path A $\to$ Path A) while crossing the transformative boundary from "in" rules to "out" rules. It embodies *continuity through transformation*.

2. *The Λ_{11} Component:*
$$\Lambda_{11}^{(\text{asym-scatter})} = -\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}$$
Interpretation: This is the complementary process for the Path B history. It is the other channel for *continuity through transformation*, where a system's fundamental nature is preserved even as its governing laws are updated.

3. *The Λ_{01} Component:*
$$\Lambda_{01}^{(\text{asym-scatter})} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}$$
Interpretation: This represents a history of *discontinuity and revolution.* A system evolving under the "in" rules for Path B is fundamentally rewritten by the interference event, emerging into a new state governed by the "out" rules for Path A.

4. *The Λ_{10} Component:*
$$\Lambda_{10}^{(\text{asym-scatter})} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}$$
Interpretation: This is the reverse revolutionary path ($A \to B$). These off-diagonal terms provide the mechanism for true novelty, modeling how a system can transition between entirely different dynamical regimes, such as in a cosmological phase transition.

3. The Lensing Model Expansion

(a) Symmetric Interferometer Lensing

$$\mathbf{U}_{\text{holo}}^{(\text{sym-com})} := [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}] \cdot \mathbf{U}_{\text{Had}}^{\dagger}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{\Lambda}}_{\mathring{\mathbf{i}}}^{\mathring{\mathbf{0}}\,(\text{sym-com})} &= |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left[-\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \;+\; |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left[\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \\ &\quad + |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \;+\; |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right]\end{aligned}$$

By extracting the operator coefficients from the ontological expansion provided, we identify the four matrix elements:

1. *The Λ_{00} Component:*
$$\Lambda_{00}^{(\text{sym-com})} = -\frac{1}{2}\left(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B\right)$$
This operator governs the amplitude for a process that starts in the control state $|\mathbf{0}\rangle_c$ and is measured to be in the same state, $|\mathbf{0}\rangle_c$, after the full operation. Its form reveals that this *"non-flipping"* channel is driven entirely by the destructive dissonance between the two paths, $\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B$, and includes a characteristic negative phase.

2. *The Λ_{01}, Λ_{10}, and Λ_{11} Components:*

$$\Lambda_{01}^{(\text{sym-com})} = \Lambda_{10}^{(\text{sym-com})} = \Lambda_{11}^{(\text{sym-com})} = +\frac{1}{2}\left(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B\right)$$

Remarkably, the other three components are identical. They represent the amplitudes for the three remaining transitions: a flip from $|\mathbf{1}\rangle_c$ to $|\mathbf{0}\rangle_c$, a flip from $|\mathbf{0}\rangle_c$ to $|\mathbf{1}\rangle_c$, and staying in the $|\mathbf{1}\rangle_c$ state.

The entire dynamic of this lensing model is governed by a single ontological process: the *Anti-Parasymmetry of Processes*, represented by the dissonance operator $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$. The model effectively filters out all constructive interference. The resulting dynamics are purely a function of the *difference* between the two evolutionary histories. The asymmetry between the Λ_{00} component (with its minus sign) and the other three identical components is a direct signature of the algebraic twist being projected back onto the measurement basis. It shows how the fundamental non-commutativity of quantum operations manifests as distinct amplitudes for different measurement outcomes.

(b) Asymmetric Interferometer Lensing

$$\mathbf{U}_{\text{holo}}^{(\text{asym-com})} := [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] \cdot \mathbf{U}_{\text{read}}^{\dagger}$$

Ontological Expansion:

$$\begin{aligned}\mathring{\mathbf{0}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{(\text{asym-com})} &= |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left[\delta\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \;+\; |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\delta^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \\ &\quad + |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\gamma\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \;+\; |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[-\gamma^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right]\end{aligned}$$

By extracting the operator coefficients from the ontological expansion provided, we can identify the four matrix elements. Note that every component is proportional to the dissonance operator, $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$.

1. *The Λ_{00} Component:*

$$\Lambda_{00}^{(\text{asym-com})} = \delta\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

This operator represents the amplitude for a process that begins in the control state prepared by $\mathbf{U}_{\text{prep}}$ and is subsequently measured in the $|\mathbf{0}\rangle_c$ state of the readout basis defined by $\mathbf{U}_{\text{read}}$, without flipping the effective path. The amplitude is weighted by the coefficients δ and β^*.

2. *The Λ_{11} Component:*

$$\Lambda_{11}^{(\text{asym-com})} = -\delta^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

This is the corresponding amplitude for a process that ends in the $|\mathbf{1}\rangle_c$ state of the readout basis, also without flipping the path.

3. *The Λ_{01} and Λ_{10} Components (Path-Flipping):*

$$\Lambda_{01}^{(\text{asym-com})} = -\gamma\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

$$\Lambda_{10}^{(\text{asym-com})} = -\gamma^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

These operators represent the amplitudes for the control state to be flipped by the process. Their magnitudes and phases are determined by the cross-terms of the preparation and readout gates.

The components of this model are *Generalized Twist Operators*. The structure is highly revealing:

1. *Universal Dissonance*: Every single channel in this process is proportional to the dissonance operator $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$. This shows that the algebraic twist isolated by the commutator $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]$ is purely a function of the *difference* between the evolutionary paths.

2. *Tunable Projections*: The complex coefficients $(\alpha, \beta, \gamma, \delta)$ from the preparation and readout gates act as "dials" that control the magnitude and phase of the dissonance operator that gets projected into each of the four final channels.

This model, therefore, describes how the fundamental algebraic *shear* between evolution and preparation can be rotated and projected into any arbitrary measurement basis, making it the essential tool for a full tomographic reconstruction of the system's non-commutative geometry.

(c) Symmetric Path Scattering Lensing

$$\mathbf{U}_{\text{holo}}^{(\text{psym-com})} := \mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$$

Ontological Expansion:

$$\begin{aligned} \mathring{\mathbf{o}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{i}}^{(\text{psym-com})} &= |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \\ &+ |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[-\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\right] \end{aligned}$$

By comparing it to the universal form $\sum_{i,j} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \Lambda_{ij}$, we can identify the four operator-valued matrix elements.

1. *The Λ_{00} and Λ_{11} Components (Diagonal):*

$$\Lambda_{00}^{(\text{psym-com})} = 0$$

$$\Lambda_{11}^{(\text{psym-com})} = 0$$

The most striking feature of this model is that its diagonal components are zero. This means that a process governed by this specific operator *always flips the control state*. There is no amplitude for a history to start in a given control state ($|\mathbf{0}\rangle_c$ or $|\mathbf{1}\rangle_c$) and remain in that same state after the full operation.

2. *The Λ_{01} Component (Path-Flipping $1 \to 0$):*

$$\Lambda_{01}^{(\text{psym-com})} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

This operator governs the transition from the control state $|\mathbf{1}\rangle_c$ to $|\mathbf{0}\rangle_c$. It describes a process where the initial algebraic twist—represented by the dissonance term $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$—is subsequently acted upon, or "filtered," by the *Path A* evolution operator, $\hat{\mathbf{U}}_A$.

3. *The Λ_{10} Component (Path-Flipping $0 \to 1$):*

$$\Lambda_{10}^{(\text{psym-com})} = -\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

This is the complementary process. It is the amplitude for flipping from $|\mathbf{0}\rangle_c$ to $|\mathbf{1}\rangle_c$. Here, the same initial twist is filtered by the *Path B* evolution operator, $\hat{\mathbf{U}}_B$.

The components of this model are *Feedback-Filtered Twist Operators*. They do not simply measure the algebraic source of interference (the commutator); they describe how that source term is itself transformed by a subsequent evolution. This represents a true dynamical feedback loop, where the structure of quantum interference is fed back into the system's dynamics, illustrating how the past evolution (embedded in the commutator) conditions the future evolution.

(d) Asymmetric Path Scattering Lensing

$$\mathbf{U}_{\text{holo}}^{(\text{pasym-com})} := \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}]$$

Ontological Expansion:

$$\begin{aligned} \mathring{\mathbf{0}}\overset{\circ}{\mathbf{\Lambda}}\mathring{\mathbf{1}}^{(\text{pasym-com})} &= |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \left[\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}})\right] \\ &\quad + |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \left[-\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}})\right] \end{aligned}$$

Extracting the operator coefficients for each matrix element yields the following:

1. *The Λ_{00} and Λ_{11} Components (Diagonal):*

$$\Lambda_{00}^{(\text{pasym-com})} = 0$$
$$\Lambda_{11}^{(\text{pasym-com})} = 0$$

As in the symmetric case, the diagonal components vanish. This reveals that the fundamental operation described by this model is a *pure path-flipping transformation*. Any history that undergoes this specific process is guaranteed to end in a control state orthogonal to its initial state.

2. *The Λ_{01} Component (Path-Flipping $1 \to 0$):*

$$\Lambda_{01}^{(\text{pasym-com})} = -\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^{\text{out}}(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}})$$

This operator describes the amplitude for a history that begins on *Path B* (under the initial "in" laws), undergoes the algebraic twist of interference, and is then transformed by the final "out" laws corresponding to *Path A*.

3. *The Λ_{10} Component (Path-Flipping $0 \to 1$):*

$$\Lambda_{10}^{(\text{pasym-com})} = \frac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^{\text{out}}(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}})$$

This is the complementary process, describing a history that begins on *Path A* ("in" laws), twists, and is subsequently transformed by the final "out" laws for *Path B*.

The components of this model are *Transformative Twist Operators*. They represent the most sophisticated process in the framework, providing a mechanism for an irreversible change in dynamics. The core of the process is the algebraic dissonance between the initial paths, $(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}})$. This "twist," generated under one set of physical laws, is then filtered through a new, potentially different set of laws ($\hat{\mathbf{U}}_A^{\text{out}}$ or $\hat{\mathbf{U}}_B^{\text{out}}$). This allows the framework to model how the very structure of quantum interference evolves across a fundamental change in the universe's dynamical regime, such as a cosmological phase transition.

The Ontological Status of Physical Reality The framework posits that the observable universe is not a singular, pre-determined entity, but is instead a dynamically selected configuration emerging from a coherent superposition of all possible evolutionary histories. The principle of *Holosymmetry* provides the mathematical and ontological engine for this emergence.

Reality as Constructive Interference: The Principle of Parasymmetric Selection The stable structures of reality—including particles, forces, and the very laws of physics—are identified with the *constructive interference patterns* that arise from the universal superposition of histories. In the language of the Symmetric Interferometer Model, these correspond to the diagonal process operators, which are proportional to the synthetic sum of path operators, $(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)$.

These are the channels where divergent evolutionary pathways align and reinforce one another, leading to a high-amplitude, stable, and persistent outcome. This process is the dynamical realization of *Parasymmetry (Synthesis)* at the level of universal evolution. The observable cosmos is, in this sense, the "bright fringe" of its own self-interference.

The Void as Sculptor: Anti-Parasymmetry and the Annihilation of Possibilities A stable reality can only be defined in contrast to the vast space of unrealized possibilities. These correspond to the *destructive interference patterns*, which are governed by the off-diagonal, dissonant process operators proportional to $(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$.

These channels of *Anti-Parasymmetry (Dissonance)* represent self-annihilating histories where potential realities cancel each other out, leaving behind a structured void. The "dark fringes" are therefore not empty nothingness, but are an active and necessary component of reality; they are the unobservable structure of cancelled possibilities that "sculpts" the observable reality by carving it out from the plenum of potentiality.

Higher-Order Coherence and the Reflexive Universe The framework's structure allows for a hierarchy of self-interaction, giving rise to two profound concepts:

1. *Second-Order Coherence*: The framework allows for the interference of interference patterns themselves. This is formally realized by models such as the *Path Scattering Operator*, $\mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}$, which describes how the outcome of one interferometric process becomes the input for a subsequent evolution. This provides a mechanism for probing the algebraic structure of quantum dynamics at a recursive level.

2. *A History-Dependent, "Learning" Universe*: The *Asymmetric Path Scattering Model* introduces irreversible evolution by allowing the "in" and "out" laws to differ ($\mathbf{U}^{\text{out}}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}^{\text{in}}_{\text{ctrl}}$). This formalizes a universe that is *reflexive*—one whose future dynamical laws can be conditioned by the quantum interference patterns of its own past.

Conclusion: The Cosmos as a Self-Actualizing System Ultimately, Holosymmetry defines the cosmos as a self-contained, self-actualizing system. It is:

1. *Self-Generating*, as it creates its own geometric arena from the Quantum Holo-State via the GNS construction.

2. *Self-Observing*, as it perpetually probes the relational structure between its own possible histories via interferometric dynamics.

3. *Self-Learning*, as it can irreversibly update its own dynamical laws based on the outcome of its self-observation.

The emergence of our reality is thus the result of a grand, recursive synthesis of all possible universal histories, governed by the elegant and complete logic of the Fourfold Dialectic Algebra.

3.8.2 Probing Second-Order Coherence

While the standard interferometric model reveals the first-order interference between two evolutionary histories, its true recursive nature is only unveiled through more sophisticated experimental protocols. We now devise two such "second-order" experiments, each designed to probe the structure of the *Symmetric Interferometer Holosymmetric Operator*, $\mathbf{U}^{(\text{sym})}_{\text{holo}}$, in a unique way.

1. The Sequential Interferometer: Interference of Outcomes This experiment probes the recursive nature of holosymmetry by running the output of one interferometer through a second, identical one. It directly measures how interference patterns themselves interfere.

The Operator: The process is governed by the square of the symmetric operator:

$$\left(\mathbf{U}^{(\text{sym})}_{\text{holo}}\right)^2 = \left(\frac{1}{2}\begin{pmatrix} \hat{\mathbf{U}}_+ & \hat{\mathbf{U}}_- \\ \hat{\mathbf{U}}_- & \hat{\mathbf{U}}_+ \end{pmatrix}\right)^2 = \frac{1}{4}\begin{pmatrix} \hat{\mathbf{U}}_+^2 + \hat{\mathbf{U}}_-^2 & \{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\} \\ \{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\} & \hat{\mathbf{U}}_-^2 + \hat{\mathbf{U}}_+^2 \end{pmatrix}$$

where $\{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\} = \hat{\mathbf{U}}_+\hat{\mathbf{U}}_- + \hat{\mathbf{U}}_-\hat{\mathbf{U}}_+$ is the anticommutator.

The Process: We apply this squared operator to the simple initial state $|\Psi_{\text{init}}\rangle = |\mathbf{0}\rangle_c \otimes |\Psi_{\text{RR}}\rangle$. The final state is determined by the first column of the resulting operator matrix:

$$|\Psi_{\text{final}}\rangle = \frac{1}{4}\left[|\mathbf{0}\rangle_c \otimes (\hat{\mathbf{U}}_+^2 + \hat{\mathbf{U}}_-^2)|\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\}|\Psi_{\text{RR}}\rangle\right]$$

Interpretation: The final measurement probabilities now depend on higher-order combinations of the path operators.

- p_0 depends on $\hat{\mathbf{U}}_+^2 + \hat{\mathbf{U}}_-^2$. This term represents the amplitude for the system to return to the $|\mathbf{0}\rangle_c$ branch after two full interference events.
- p_1 depends on the anticommutator $\{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\}$. This term represents the amplitude for the system to be "flipped" to the $|\mathbf{1}\rangle_c$ branch by the sequence of interferences.

This experiment directly measures the *interference of interference patterns*, revealing the algebraic structure $(\hat{\mathbf{U}}_+^2, \hat{\mathbf{U}}_-^2, \{\hat{\mathbf{U}}_+, \hat{\mathbf{U}}_-\})$ that governs the system's recursive evolution.

2. The Tomographic Interferometer: Probing the Operator Structure This experiment probes the operator's structure by preparing a general "polarized" input state and observing how the operator transforms it. It is a method of quantum process tomography.

The Process: We apply the standard operator $\mathbf{U}_{\text{holo}}^{(\text{sym})}$ once, but to a general initial state:

$$|\Psi_{\text{init}}\rangle = (\alpha|\mathbf{0}\rangle_c + \beta|\mathbf{1}\rangle_c) \otimes |\Psi_{\text{RR}}\rangle$$

We have already derived the final state for this process:

$$|\Psi_{\text{final}}\rangle = \frac{1}{2}\left[|\mathbf{0}\rangle_c \otimes \left(\alpha\hat{\mathbf{U}}_+ + \beta\hat{\mathbf{U}}_-\right)|\Psi_{\text{RR}}\rangle + |\mathbf{1}\rangle_c \otimes \left(\alpha\hat{\mathbf{U}}_- + \beta\hat{\mathbf{U}}_+\right)|\Psi_{\text{RR}}\rangle\right]$$

Interpretation: The final amplitudes are now complex mixtures of the initial amplitudes α and β. The mixing is governed by the off-diagonal terms of the operator matrix, $\frac{1}{2}\hat{\mathbf{U}}_-$. This directly reveals the operator's *"scattering"* nature.

By preparing various input states (i.e., by varying α and β) and measuring the corresponding output states, one can fully reconstruct the matrix elements of $\mathbf{U}_{\text{holo}}^{(\text{sym})}$. This tomographic approach allows one to measure the operator's structure itself, providing a complete characterization of the interferometric process.

Holosymmetry: The Universe as a Quantum Interferometer At the heart of the Interdependent Quantum Reality (IQR) framework lies a radical proposition: that reality is not described by a single, unfolding history, but by a coherent superposition of all possible evolutionary histories. The principles of *Parasymmetry* and *Holosymmetry* provide the architecture for this vision.

- *Parasymmetry* is the language of interaction. It governs how the fundamental modes of Symmetry and Antisymmetry combine and entangle across the registers of Primordial Quantum Singularities, creating the rich tapestry of quantum states under a *given* set of dynamical rules.
- *Holosymmetry* is the meta-language of evolution. It does not operate on states, but on the *very rules of Parasymmetry themselves*. It provides the mechanism for placing different evolutionary laws—different universal histories—into a grand, coherent superposition.

The models we have just detailed are the experimental protocols for this "metaphysical laboratory".

The Interferometer: A Cosmic Comparison Engine The *Interferometer Model*, defined by the operator $\mathbf{U}_{\text{holo}}^{(\text{sym})} = \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}}$, acts as a cosmic comparison engine. Its purpose is to answer a profound question: "Given two possible sets of physical laws (Path A and Path B), how different are they?"

By preparing a superposition, evolving each branch under a different dynamic, and recombining them, the interferometer produces a final measurement on the control qubit. This measurement is a direct readout of the *relational distinguishability* between two entire universal histories. The interference pattern is not of particles in space, but of realities in the space of possibilities.

The Path Scattering Model: A Self-Referential Universe The *Path Scattering Model*, $\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}$, describes a more complex and intimate process: a universe capable of *dynamical feedback*.

This is a model for a self-referential reality. It describes a process where the universe evolves along one path, is subjected to an interference event that makes it "aware" of its other possibilities, and then alters its subsequent evolution based on the outcome of that interference. It is a framework for a learning universe, where the laws of tomorrow may depend on the quantum interference of all its yesterdays.

The Nature of Reality and Physical Law This leads us to a final, profound reinterpretation of existence itself. The universe, in this view, is a single, vast, self-interfering quantum system. The "reality" we observe, with its apparently stable and unique physical laws, is merely the "bright fringe" in this cosmic interference pattern—the pathway of maximal constructive interference among an infinity of competing evolutionary possibilities. Physical laws are not immutable, Platonic edicts imposed from without. They are *emergent and state-dependent regularities*. They are the stable, self-reinforcing patterns that have won out in the universe's continuous process of self-observation and self-creation. The very fabric of spacetime, the particles within it, and the rules they obey are all different facets of a single, indivisible, and recursively self-interfering quantum state.

3.8.3 The Master Holosymmetric Operator

Let $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}$ be bounded operators on the dual-register Hilbert space $\mathcal{H}_{\mathrm{RR}}^{(2n)}$. Relative to the control computational basis $\{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$, define the *Master Holosymmetric Operator* (general form)

$$\mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})} := \overset{\circ}{\underset{\mathring{0}}{\mathbf{\Lambda}}}{}_{\mathring{1}}^{(\mathrm{General})} = |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \mathbf{A} + |\mathbf{0}\rangle_c\langle\mathbf{1}|_c \otimes \mathbf{B} + |\mathbf{1}\rangle_c\langle\mathbf{0}|_c \otimes \mathbf{C} + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \mathbf{D}.$$

This gives a complete 2×2 control–register *parametrization* of holosymmetric operations; the physically admissible (unitary) protocols are those choices of $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ that satisfy the block–unitarity constraints below.

Remark 3.19 (Block unitarity of the master operator)**.** Writing $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})}$ as the 2×2 block $\left(\begin{smallmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{smallmatrix}\right)$ on $\mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$, unitarity $\left(\mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})}\right)^\dagger \mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})} = \mathbb{I} = \mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})} \left(\mathbf{U}_{\mathrm{holo}}^{(\mathrm{gen})}\right)^\dagger$ is equivalent to

$$\mathbf{A}^\dagger\mathbf{A} + \mathbf{C}^\dagger\mathbf{C} = \mathbb{I}, \quad \mathbf{B}^\dagger\mathbf{B} + \mathbf{D}^\dagger\mathbf{D} = \mathbb{I}, \quad \mathbf{A}^\dagger\mathbf{B} + \mathbf{C}^\dagger\mathbf{D} = 0,$$

and

$$\mathbf{A}\mathbf{A}^\dagger + \mathbf{B}\mathbf{B}^\dagger = \mathbb{I}, \quad \mathbf{C}\mathbf{C}^\dagger + \mathbf{D}\mathbf{D}^\dagger = \mathbb{I}, \quad \mathbf{A}\mathbf{C}^\dagger + \mathbf{B}\mathbf{D}^\dagger = 0.$$

These identities hold automatically in the canonical models obtained from controlled unitaries and Hadamard pre/post-rotations.

Remark 3.20 (Master valuation)**.** For control $|\mathbf{a}\rangle_c \to |\mathbf{b}\rangle_c$, the holosymmetric effect on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ is

$$E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})} := \langle\mathbf{a}|_c\, \mathbf{U}_{\mathrm{holo}}^\dagger \Big(|\mathbf{b}\rangle\langle\mathbf{b}|_c \otimes \mathbb{I}\Big)\, \mathbf{U}_{\mathrm{holo}}\, |\mathbf{a}\rangle_c,$$

so the Holothesis valuation is $v_{\mathrm{Holothesis}}(\rho) = \mathrm{Tr}\Big(\rho\, E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}\Big)$ (cf. Definition 1.18).

Corollary 3.21 (Basis specialization: computational control)**.** *If* $|\mathbf{a}\rangle_c, |\mathbf{b}\rangle_c \in \{|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c\}$ *and* $\mathbf{U}_{holo} = \left(\begin{smallmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{smallmatrix}\right)$*, then*

$$E^{(0\to0)} = \mathbf{A}^\dagger\mathbf{A}, \quad E^{(0\to1)} = \mathbf{C}^\dagger\mathbf{C}, \quad E^{(1\to0)} = \mathbf{B}^\dagger\mathbf{B}, \quad E^{(1\to1)} = \mathbf{D}^\dagger\mathbf{D}.$$

For arbitrary control bases realized by $\mathbf{U}_{\mathrm{prep}}, \mathbf{U}_{\mathrm{read}} \in \mathcal{U}(\mathcal{H}_c)$*, use Remark 3.20 with* $|\mathbf{a}\rangle_c = \mathbf{U}_{\mathrm{prep}}|\mathbf{a}_0\rangle_c$ *and* $|\mathbf{b}\rangle_c = \mathbf{U}_{\mathrm{read}}|\mathbf{b}_0\rangle_c$*.*

Recovery of Canonical Models

Each specific physical model emerges by imposing particular constraints on the four process operators:

1. The Symmetric Interferometer Model

Definition: $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})} = \mathbf{U}_{\mathrm{Had}} \cdot \mathbf{U}_{\mathrm{ctrl}} \cdot \mathbf{U}_{\mathrm{Had}}$

Process Operators:

$$\mathbf{A} = \mathbf{D} = \frac{1}{2}(\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)(Parasymmetricsynthesis)$$
$$\mathbf{B} = \mathbf{C} = \frac{1}{2}(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)(Anti - parasymmetricdissonance)$$

Physical Interpretation: The interferometer realizes perfect symmetry between the diagonal and off-diagonal channels, encoding constructive and destructive interference between evolutionary paths.

2. The Symmetric Path Scattering Lensing Model

Definition: $\mathbf{U}_{\text{holo}}^{(\text{lens,sym})} = \mathbf{U}_{\text{ctrl}} \cdot [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{Had}}]$

Process Operators:

$$\mathbf{A} = \mathbf{D} = 0$$
$$\mathbf{B} = \frac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$
$$\mathbf{C} = -\frac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$$

Physical Interpretation: This purely off-diagonal structure isolates the algebraic non-commutativity between paths, always inducing control-state flips.

3. The Asymmetric Interferometer Model

Definition: $\mathbf{U}_{\text{holo}}^{(\text{asym-int})} = \mathbf{U}_{\text{read}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{prep}}$

Process Operators:

$$\mathbf{A} = \gamma\alpha\hat{\mathbf{U}}_A - \delta^*\beta\hat{\mathbf{U}}_B$$
$$\mathbf{B} = -\gamma\beta^*\hat{\mathbf{U}}_A - \delta^*\alpha^*\hat{\mathbf{U}}_B$$
$$\mathbf{C} = \delta\alpha\hat{\mathbf{U}}_A + \gamma^*\beta\hat{\mathbf{U}}_B$$
$$\mathbf{D} = -\delta\beta^*\hat{\mathbf{U}}_A + \gamma^*\alpha^*\hat{\mathbf{U}}_B$$

Physical Interpretation: The asymmetric parameters (α, β) and (γ, δ) enable full tomographic control, allowing arbitrary preparation and measurement bases.

4. The Asymmetric Path Scattering Model

Definition: $\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} = \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{\text{in}}$

Process Operators:

$$\mathbf{A} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}$$
$$\mathbf{B} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}$$
$$\mathbf{C} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_A^{\text{in}}$$
$$\mathbf{D} = -\tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B^{\text{out}}\hat{\mathbf{U}}_B^{\text{in}}$$

Physical Interpretation: This model captures irreversible transformations where "in" laws evolve to "out" laws, modeling phase transitions or dynamical feedback.

5. The Asymmetric Interferometer Lensing Model

Definition: $\mathbf{U}_{\text{holo}}^{(\text{lens,asym-int})} = [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] \cdot \mathbf{U}_{\text{read}}^{\dagger}$

Process Operators:

$$\begin{aligned}\mathbf{A} &= \delta\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\\ \mathbf{B} &= -\gamma\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\\ \mathbf{C} &= -\gamma^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\\ \mathbf{D} &= -\delta^*\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)\end{aligned}$$

Physical Interpretation: Every channel is proportional to the dissonance operator, isolating the algebraic interference generated by arbitrary preparation.

6. The Asymmetric Path Scattering Lensing Model

Definition: $\mathbf{U}_{\text{holo}}^{(\text{lens,asym-scatter})} = \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot [\mathbf{U}_{\text{Had}}, \mathbf{U}_{\text{ctrl}}^{\text{in}}]$

Process Operators:

$$\begin{aligned}\mathbf{A} &= 0\\ \mathbf{B} &= -\tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^{\text{out}}\left(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}}\right)\\ \mathbf{C} &= \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B^{\text{out}}\left(\hat{\mathbf{U}}_A^{\text{in}} - \hat{\mathbf{U}}_B^{\text{in}}\right)\\ \mathbf{D} &= 0\end{aligned}$$

Physical Interpretation: The purely off-diagonal form ensures control-state flipping, capturing transformative dynamics through algebraic twists.

Profound Insights from the Master Operator

1. Universal Control Architecture All holosymmetric dynamics—whether representing comparison, feedback, or algebraic analysis—share a single universal architecture: the entanglement of a two-level control system with a larger register system. The four matrix elements govern the complete logic of control-state transitions.

2. Complete Phase Space of Quantum Dynamics The four process operators $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ serve as coordinates in an abstract space encompassing all possible holosymmetric dynamics. Each point represents a unique evolutionary law, with canonical models occupying special symmetric locations.

3. Possibility versus Actuality The Master Operator represents the entire space of mathematical possibility so that specific models represent physical actualities derived through symmetry-imposing constraints. Physical laws emerge from mathematical possibility through the application of specific operational sequences.

4. Generative Framework for New Physics The Master Operator is both descriptive and generative. By exploring novel choices for the process operators—beyond the canonical models—one can theoretically predict new quantum processes and interactions. It provides a complete roadmap for systematic exploration of quantum dynamics.

A Common Architecture for Holosymmetry

The Interferometer, Path–Scattering, and Lensing presentations at first read like different experiments designed for different questions. But each is, in fact, a particular *realization* of the same backbone: a control qubit coherently addressing two global histories on the dual PQS registers and then recombining them. What follows is not a "unification" in the sense of a single fundamental physical theory; it is a *master parametrization* that gathers all such realizations into one mathematical form while preserving their operational diversity.

Concretely, every holosymmetric protocol can be expanded in the control basis as

$$\mathring{\mathbf{0}}\mathring{\mathbf{\Lambda}}\mathring{\mathbf{1}} \;=\; \sum_{i,j\in\{0,1\}} |\mathbf{i}\rangle_c\langle\mathbf{j}|_c \otimes \Lambda_{ij},$$

and by allowing the four block operators Λ_{ij} to be arbitrary (subject to unitarity when the whole is a physical process), we arrive at the *Master Holosymmetric Operator* with blocks $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$. Individual models then appear by imposing principled constraints on these blocks—e.g. symmetry conditions, commutator filters, or structured products—rather than by summing "partial operators." This is why "adding models together" is conceptually wrong (like adding a reflection to a rotation): each model is a *complete* protocol optimized for a specific probe of relational dynamics.

What the blocks mean. In the computational control basis, the four process operators carry a transparent operational meaning:

1. $\mathbf{A}$: amplitude map for staying in $|\mathbf{0}\rangle_c$ ($0\to0$ channel),
2. $\mathbf{B}$: map for flipping $|\mathbf{1}\rangle_c\to|\mathbf{0}\rangle_c$ ($1\to0$),
3. $\mathbf{C}$: map for flipping $|\mathbf{0}\rangle_c\to|\mathbf{1}\rangle_c$ ($0\to1$),
4. $\mathbf{D}$: amplitude map for staying in $|\mathbf{1}\rangle_c$ ($1\to1$).

Different holosymmetric "presentations" correspond to different *relations* among $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$:

- **Interferometer:** blocks built from the *sum/difference* of path histories, e.g. $\mathbf{A} = \mathbf{D} \propto (\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)$ and $\mathbf{B} = \mathbf{C} \propto (\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$ (up to chosen control rotations).
- **Path–Scattering:** blocks as *iterated/hybrid* histories, e.g. $\mathbf{A} \propto \hat{\mathbf{U}}_A^2$, $\mathbf{D} \propto \hat{\mathbf{U}}_B^2$, $\mathbf{B} \propto \hat{\mathbf{U}}_B\hat{\mathbf{U}}_A$, $\mathbf{C} \propto \hat{\mathbf{U}}_A\hat{\mathbf{U}}_B$.
- **Lensing (commutator forms):** blocks proportional to the *difference* $\Delta\mathbf{U} := \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B$, obtained by control pre/post rotations that cancel the sum and isolate the algebraic "twist."

These are not ad hoc recipes; they are slice choices of the same 2×2 block architecture.

What this buys us. The master parametrization does four practical things: (i) it *classifies* every holosymmetric protocol by its block structure; (ii) it *derives* familiar models as special constraints; (iii) it *generates* new probes by proposing admissible block relations; and (iv) it *clarifies* how mathematical structure (sums, products, commutators of histories) maps to physical readouts. Nothing here asserts a unification of fundamental forces or a theory of everything; rather, it provides a single architectural language in which the diverse holosymmetric experiments are different, symmetry-related "dialects."

Reading the master blocks: symmetry ⇒ protocol. The physical character of a holosymmetric operation is fixed by the *relations* among its four block operators $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ (subject to the block–unitarity constraints). What makes the framework powerful is that the canonical presentations appear as *simple symmetry slices* of the same 2×2 architecture:

1. **Symmetric interferometer.** Impose maximal control symmetry: $\mathbf{A} = \mathbf{D}$ (diagonal symmetry) and $\mathbf{B} = \mathbf{C}$ (off–diagonal symmetry). With a Hadamard–Control–Hadamard sequence on the control, the blocks take the familiar *sum/difference* form, $\mathbf{A} = \mathbf{D} \propto (\hat{\mathbf{U}}_A + \hat{\mathbf{U}}_B)$ and $\mathbf{B} = \mathbf{C} \propto (\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B)$, so the "same–port'' channels measure constructive synthesis and the "opposite–port'' channels measure dissonance.

2. **Path–scattering lensing (pure flips).** In the complementary sector with $\mathbf{A} = \mathbf{D} = 0$, the operation is *purely off–diagonal*: every run flips the control $(0 \leftrightarrow 1)$. This guarantees that the readout isolates interference–mediated transitions rather than same–port persistence.

3. **Asymmetric families (tomography and irreversibility).** Breaking the equalities $\mathbf{A} = \mathbf{D}$ and/or $\mathbf{B} = \mathbf{C}$ introduces tunable asymmetries. These parameters support full *tomographic control* (asymmetric interferometers via arbitrary prepare/read on the control) and model *history transformation* (asymmetric path–scattering), where the post–interference dynamics differ from the pre–interference ones.

The block–operator landscape. Taken together, the four blocks define a convenient "state space'' for holosymmetric dynamics: each admissible choice of $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ (that satisfies block–unitarity) specifies a distinct protocol on $\mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$. The canonical models occupy highly symmetric loci with clear operational meaning; the surrounding continuum contains many legitimate but as–yet unexplored processes.

This perspective highlights a familiar pattern in physics: the gap between *what can be written* and *what is realized*. The Master Operator provides the mathematical envelope; *physical* models emerge by imposing constraints—symmetry, causality, resource or calibration choices—that pick out viable points in the block–operator landscape. Thus the master form is not merely retrospective "unification'' of known cases; it is a *generative* tool for proposing new protocols and experiments.

Directions to explore.

- *Asymmetric pure flips:* $\mathbf{A} = \mathbf{D} = 0$ with $\mathbf{B} \neq \mathbf{C}$ to study nonreciprocal path–flipping dynamics.

- *Algebraic constraints:* enforce relations such as $\mathbf{AD} = \mathbf{BC}$ (or their adjoint variants) to probe hidden conservation laws or selection rules.
- *Time–structured blocks:* allow $\mathbf{A}(t), \mathbf{B}(t), \mathbf{C}(t), \mathbf{D}(t)$ to vary across the protocol, modeling staged or feedback–driven holosymmetric evolutions.

Completeness of Holosymmetry: Architecture as Ontology

Having introduced the Master Holosymmetric Operator as a common 2×2 control–register parametrization (Section 3.8.3), we can now ask a precise question: *Is this description complete for the binary holosymmetric architecture?* By "complete," we mean *expressively exhaustive* given the fixed ingredients (a qubit control and two PQS registers) and the equivalence moves of (H4 see Definition 3.18), not a claim about all conceivable physics.

Formal completeness within the binary architecture The holosymmetric Hilbert space is $\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)}$ with $\dim \mathcal{H}_c = 2$. Every linear map on $\mathcal{H}_{\text{Holo}}$ therefore admits a 2×2 block form relative to the control basis,

$$\mathbf{U} = \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix},$$

and the *physically admissible* (unitary) protocols are precisely those blocks that satisfy the block–unitarity constraints (see remark after (3.8.3)). It follows that the Master Holosymmetric Operator is *expressively complete*: any binary-controlled holosymmetric process is a point $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ in this block-operator landscape, while specific presentations (Interferometer, Path–Scattering, Lensing) are obtained by imposing principled relations among the blocks (symmetries, commutator filtering, iterated/hybrid compositions) and by controlbasis choices (H4 see Definition 3.18).

Why this architecture: structure mirrors ontology The binary architecture is not an arbitrary convenience; it instantiates the *Axiom/Principle of Duality* (Definition 2.100) at the operational level.

Control qubit as dialectic arbiter A two-dimensional control is the minimal quantum system that can encode the fundamental duality (Thesis/Symmetry $\leftrightarrow$ Antithesis/Antisymmetry). In the computational control basis, $|\mathbf{0}\rangle_c$ and $|\mathbf{1}\rangle_c$ select complementary assignments of *which* global regime runs on *which* register; superpositions coherently address *both* assignments at once and thus enable interference of histories.

Dual registers as dialectic canvas Two disjoint PQS registers are the twin stages on which the dual regimes unfold in parallel. Their exchange symmetry ($A \leftrightarrow B$) and the control's $|\mathbf{0}\rangle_c \leftrightarrow |\mathbf{1}\rangle_c$ swap echo the same ontological duality, producing a self-similar pattern: the dialectic appears in the ontic labels, in the control basis, and in the two-register geometry.

The block–operator landscape and its use The four blocks $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ provide a convenient "state space'' for holosymmetric dynamics (subject to block–unitarity). Highly symmetric loci reproduce the canonical models with clear operational meaning; the surrounding continuum hosts admissible but as-yet unexplored processes. Thus the master form does more than collect known cases: it *generates* new probes by proposing lawful relations among the blocks and by choosing control prepare/readout maps. Valuations remain Born-valued via the induced effect $E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ (cf. Definition 1.18 and Remark 3.20).

Paths to greater complexity (beyond the binary axiom) Completeness here is *relative* to the binary design. Enlarging the axioms enlarges the operator class:

1. **Higher-dimensional control** ($\mathbb{C}^3$, $\mathbb{C}^k$): a 3×3 (or $k \times k$) block operator representing coherent superpositions of three (or k) global histories; a natural setting for ternary or multiway dialectics.

2. **Additional registers**: more stages for concurrent histories, typically paired with higher-dimensional control to address them coherently.

3. **Hierarchical control**: nested controls (meta-controls) that program how lower-level controls act, modeling layered evolutionary choices or regime changes.

These are principled generalizations, but they lie *beyond* the binary axiom and require new completeness statements.

Why this matters

1. **Exhaustive classification.** Any binary-controlled holosymmetric protocol lies somewhere in the block–operator landscape; the canonical models are symmetric slices.

2. **Principled constraints.** Physical models are not arbitrary; they are constrained points picked out by symmetry, causality, resource, or calibration requirements.

3. **Predictive leverage.** Unexplored regions of $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D})$ suggest new, testable protocols (e.g., asymmetric pure-flip dynamics, algebraically constrained blocks, time-structured blocks).

4. **Foundational clarity.** The "binary limitation'' is a feature: it encodes the dialectic of duality in the architecture, ensuring that the mathematics faithfully reflects the ontology.

Completeness as a platform for discovery The Master Holosymmetric Operator is complete *because* it fully embraces the binary constraints and explores all their consequences. It validates the coherence of the duality principle, provides a full classification of binary holosymmetric phenomena, and points cleanly to higher-dimensional generalizations when (and only when) the foundational axioms are extended. In this sense, the framework carries both its own completion and the seeds of its future evolution.

The Generative Axiom: Primacy of Duality At the base of the edifice is a single axiom: the *Principle of Duality* (Definition 2.100). Stated plainly: to assert the existence of any ontological state is simultaneously to co-assert the existence of its complementary anti-state. From this one premise, the *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16) unfolds as a sequence of necessities rather than a list of independent postulates:

1. *Thesis (Symmetry,* $\mathring{\mathbf{0}}$*)* — the initial stance,
2. *Antithesis (Antisymmetry,* $\mathring{\mathbf{1}}$*)* — its compelled counter-statement,
3. *Synthesis (Parasymmetry)* — the rule of coherent composition of the pair,
4. *Holothesis (Holosymmetry)* — the meta-rule that superposes and compares *entire* dynamical histories.

This fourfold is the theory's logical engine: the richness that follows is the systematic elaboration of the tension and interplay between Symmetry and Antisymmetry, made quantitative by Born-valued semantics (Definition 1.18).

Self-Similar Architecture: from Duality to n-Body Configurations Extending the framework to many controls or many registers does not introduce new axioms; it reuses the same duality in a higher-combinatorial setting.

1. *n-qubit control.* Replacing a single control qubit by $(\mathbb{C}^2)^{\otimes n}$ yields 2^n addressable control channels. Each basis label is still a tensor of the binary primitives $|\mathbf{0}\rangle_c, |\mathbf{1}\rangle_c$; the governing logic remains pairwise duality, now composed across qubits.
2. *n-register geometry.* Likewise, an n-register scene distributes dialectical assignments across more loci. One subset may run coupled (synthetic/parasymmetric) dynamics while another runs decoupled (analytic) dynamics; the *types* of assignment still come from the original fourfold.

In this sense the architecture is *recursively self-similar*: the rule that organizes a single PQS also organizes a network of them.

Infinite Complexity via Quantum Realization Each site is not a classical bit nor even a bare qubit; it is a *Primordial Quantum Singularity (PQS)* with a local modal space $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$. Thus even a single locus supports a continuum of states; n loci span an astronomically large space. When we speak of the two "paths" $\hat{\mathbf{U}}_A$ (coupled) and $\hat{\mathbf{U}}_B$ (decoupled), these are *archetypal families*—coarse descriptions of whole sectors of histories—rather than two literal, isolated trajectories. Operationally, they stand in for path-integral classes dominated by coupling vs. decoupling.

Holosymmetry as a Coarse-Graining Instrument The holosymmetric formalism—captured compactly by the *Master Holosymmetric Operator* (the 2×2 control–register block with entries $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}$)—is the tool that makes this complexity tractable. It does not enumerate every microscopic history; it *selects* a small number of macro-classes (e.g., coupled vs. decoupled sectors, or their structured composites), and computes the precise quantum interference *between classes*. Different presentations (interferometer, path-scattering, lensing) correspond to different lawful relations among the blocks and different control bases (cf.Definition 3.18 (H4) equivalences), while all valuations remain Born expectations of the induced effects on the registers (Definition 1.18, Remark 3.20). In short, Holosymmetry does not erase detail; it makes detail *legible* by posing the right binary question—and then reading the interference it induces.

Duality in Cosmic Evolution

The architecture built from Primordial Quantum Singularities (PQSs) and the Fourfold Algebra is *recursively self-similar*: the same logical rule that organizes a single quantum locus also organizes families of histories at cosmological scale. The same pattern scales to the path-integral arena. The total evolution is a coherent sum over histories of the *Gaiamiti* and *Tantrakyma* fields,

$$\mathbf{U}_{\text{total}} = \int \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,,$$

a formal integral over an infinite space of possibilities. To render this operationally legible, introduce a *modularity functional* $\mathcal{M}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]$ that quantifies relational separability. A threshold ϵ then defines two archetypal *classes* of histories—the macroscopic echo of the basic duality:

$$\text{Decoupled class (Antithesis):}\quad \hat{\mathbf{U}}_B := \int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,,$$

$$\text{Coupled class (Synthesis):}\quad \hat{\mathbf{U}}_A := \int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,.$$

These are *archetypal families*, not single trajectories: $\hat{\mathbf{U}}_A$ summarizes histories dominated by holistic/entangled evolution, while $\hat{\mathbf{U}}_B$ summarizes histories dominated by modular/separable evolution. Different calibrations of ϵ amount to different but (H4)-equivalent (Definition 3.18) coarse-grainings of the same duality class.

Fractal self-similarity across scales The pattern repeats without multiplying principles. At the *local* level, Duality generates the binary modes within a single PQS ($\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$). At the *inter-PQS* level, Parasymmetry organizes coherent composition across loci. At the *cosmic* level, Holosymmetry interrogates the two grand, interfering super-classes of histories (*Coupled* vs. *Decoupled*) via a control-addressed comparison on dual registers. The universe, on this reading, is a dialectical computation of itself: what we observe is the synthesized outcome of a fundamental binary tension, made quantitative by effects and their Born valuations (and realized, in the emergent layer, by the GNS representation).

3.8.4 From Duality to the Architecture of the Cosmos

The Primordial Quantum Singularity (PQS) and Fourfold Algebra framework describes a universe that is *recursively self-similar*: a single axiom—the *Principle/Axiom of Duality* (Definition 2.100 and Section 1.2.6)—generates structure at every scale, from a single locus of existence to superposed families of cosmic histories. (This is a claim of *architectural* completeness within the adopted axioms, not a claim of a final unification of all physics.)

1. The Endowment of the Primordial Quantum Singularity The fundamental unit is the *Primordial Quantum Singularity* $\mathfrak{B}_x$ (cf. Section 1.3). It is not a geometric point but a structured, operator-theoretic locus whose specification internalizes the core principles.

1. *Generative logic.* Each PQS carries the full *Fourfold Dialectic Algebra of Symmetry* (Definition 1.16): from the dual pair *Symmetry/Thesis* $\left(\mathring{\mathbf{0}}\right)$ and *Antisymmetry/Antithesis* $\left(\mathring{\mathbf{1}}\right)$ follow their coherent composition *Parasymmetry/Synthesis* and the meta-principle *Holosymmetry/Holothesis* that compares entire processes (cf. Sections 1.2.1 to 1.2.3 and 3.8). Ontological labels are pre-geometric anchors, not ordinary qubit states (cf. Remark 1.22); their truth semantics are Born-valued (Definition 1.18).

2. *Physical substrate.* This logic is realized inside the Algebra of Observables $\mathcal{A}(\mathcal{C}_d)$ (Definition 1.32) by two fundamental operator families: the *Gaiamiti field* $\{\hat{\mathbf{\Phi}}_{\vec{r}}\}$ (sources of geometric potential) and the *Tantrakyma field* $\{\hat{\mathbf{\Theta}}_{\vec{r}}\}$ (sources of matter-like excitations) (cf. Definitions 6.118 and 6.142). Their holosymmetric coupling is succinctly denoted

$$\hat{\Omega}_{\vec{r}} \;:=\; \mathring{\Lambda}_{\hat{\Phi}\hat{\Theta}},$$

emphasizing that geometry and matter appear as inseparable facets of the same PQS-based construction. Locally, the modal state space is $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$, providing the $(0,1)$ sector (Thesis/Antithesis) and its parasymmetric axis as the basic logical qubit with complementary probe.

2. The Nature of a Universal History A *universal history* is a concrete object in the theory: a complete configuration of the *Gaiamiti* and *Tantrakyma* fields over the emergent manifold $\mathcal{X}_q$ (cf. Definitions 6.118 and 6.142). Its dynamics are governed by the *Total Relational Action* $S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]$, which assigns to each history a complex phase and thereby determines interference. The total evolution is the coherent sum over this (formal) space of field configurations, expressed by the path integral

$$\mathbf{U}_{\text{total}} = \int \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,.$$

In words: $\mathbf{U}_{\text{total}}$ encodes all co-evolving histories of geometry and matter, each weighted by its action, and provides the arena in which holosymmetric comparisons of histories become operational.

3. Holosymmetry and the Duality of Histories *Holosymmetry* is the mechanism that renders this infinity of histories experimentally legible. It partitions the history space into two archetypal *classes*—the highest-level expression of the Principle of Duality—using a *modularity functional* $\mathcal{M}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]$ that quantifies relational separability:

- *Coupled class (Thesis of Synthesis):* the evolutionary operator

$$\hat{\mathbf{U}}_A := \int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,,$$

  summing histories that are predominantly holistic/entangled (the dynamical expression of *Parasymmetry/Synthesis*).

- *Decoupled class (Antithesis of Synthesis):* the operator

$$\hat{\mathbf{U}}_B := \int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,,$$

  summing histories that are predominantly modular/separable (the complementary dynamical sector).

This yields two *equivalent* but conceptually distinct definitions of the archetypal path operators:

1. **Foundational (path-integral) definition:** constrained sums over families of Gaiamiti/-Tantrakyma histories as above;

2. **Operational (protocol) definition:** compositions of elementary coupled and decoupled evolutions, $\hat{\mathbf{U}}_A, \hat{\mathbf{U}}_B \in \langle U_G^{(\odot)}, U_N^{(\odot)} \rangle$, realized on dual PQS registers and addressed by a control (cf. Section 3.8).

Their equivalence is a cornerstone of internal consistency: the macro-classes defined by the path-integral coarse-graining coincide with those realized by the control-addressed circuitry, and both induce the same holosymmetric effects $E_{\text{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ and Born-valued valuations (cf. Definition 1.18 and Remark 3.20). Thus the same binary dialectic that organizes a single PQS also partitions the infinite set of cosmic histories into two interfering super-classes—*Coupled* vs. *Decoupled*—exhibiting a cosmos that is profoundly relational and recursively self-similar.

A Path Integral Synthesis of Universal Histories

At the most foundational level, a "universal history'' is a complete configuration of the *Gaiamiti field* $\hat{\mathbf{\Phi}}$ and the *Tantrakyma field* $\hat{\mathbf{\Theta}}$ over the emergent manifold $\mathcal{X}_q$, with dynamics governed by the *Total Relational Action* $S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]$. The total amplitude for evolution is a path integral over all histories. Holosymmetry coarse–grains this infinite space into two archetypal *families*, using a modularity functional $\mathcal{M}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]$ that quantifies relational separability.

Coupled (Parasymmetric) family $\hat{\mathbf{U}}_A$. Histories that are predominantly holistic/entangled ($\mathcal{M} < \epsilon$):

$$\hat{\mathbf{U}}_A := \int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}. \tag{3.37}$$

Decoupled (Modular) family $\hat{\mathbf{U}}_B$. Histories that are predominantly modular/separable ($\mathcal{M} > \epsilon$):

$$\hat{\mathbf{U}}_B := \int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{i\, S_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}. \tag{3.38}$$

Conventions. Overall normalization/phase factors for the path integrals are suppressed; operationally, these are fixed by embedding in the controlled, unitary holosymmetric circuits below.

Operational bridge. The controlled evolution used across the holosymmetric presentations is

$$\mathbf{U}_{\text{ctrl}} = |\mathbf{0}\rangle_c\langle\mathbf{0}| \otimes \hat{\mathbf{U}}_A + |\mathbf{1}\rangle_c\langle\mathbf{1}| \otimes \hat{\mathbf{U}}_B, \tag{3.39}$$

from which the interferometric, path–scattering, and lensing operators are obtained by the prescribed pre/readout rotations on $\mathcal{H}_c$ and fixed-order compositions (see (H4) equivalences and the model definitions).

Robustness of the partition. The split induced by $\mathcal{M}$ is a coarse–graining: small shifts of ϵ or monotone reparametrizations $\mathcal{M} \mapsto f(\mathcal{M})$ leave the induced family of holosymmetric effects (and thus Born valuations) unchanged up to unitary equivalence on the registers (cf. Definition 3.18).

1. The Interferometer Model: Path Integrals in Superposition

The interferometer protocols measure interference between the two families of histories. Their core is the controlled evolution operator $\mathbf{U}_{\text{ctrl}}$, whose path–integral form is

$$\mathbf{U}_{\text{ctrl}} = |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \left(\int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{i\, S_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]} \right) \;+\; |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \left(\int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{i\, S_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]} \right). \tag{3.40}$$

Equivalently, using the archetypal operators $\hat{\mathbf{U}}_A$ and $\hat{\mathbf{U}}_B$ defined in (3.37)–(3.38),

$$\mathbf{U}_{\text{ctrl}} = |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_A + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_B. \tag{3.41}$$

The full symmetric interferometer is then $\mathbf{U}^{(\text{sym})}_{\text{holo}} = \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}}$, with $\mathbf{U}_{\text{Had}}$ a fixed control rotation on $\mathcal{H}_c$; outcome channels read the constructive/destructive combination of the two families.

2. The Path Scattering Model: Products of Path Integrals

Path–scattering protocols describe dynamical feedback. Their operators are sequential compositions of $\mathbf{U}_{\text{ctrl}}$ separated by a fixed control rotation (e.g. $\mathbf{U}_{\text{Had}}$), producing *operator products* of the archetypal path–integral evolutions.

Symmetric Path Scattering

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}.$$

In block form this yields, for the $|\mathbf{0}\rangle \to |\mathbf{0}\rangle$ channel,

$$\Lambda_{00} = \frac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^{\,2} = \frac{1}{\sqrt{2}}\Big(\int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\text{total}}}\Big)\Big(\int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\text{total}}}\Big), \tag{3.42}$$

i.e. a self-reinforcing coupled history; off-diagonal components such as $\propto \hat{\mathbf{U}}_B\hat{\mathbf{U}}_A$ represent path-switching feedback.

Asymmetric Path Scattering

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} = \mathbf{U}_{\text{ctrl}}^{\text{out}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}^{\text{in}},$$

modeling an irreversible change of regime. The process operators are products of *distinct* constrained integrals, e.g.

$$\Lambda_{00}^{(\text{asym})} = \frac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^{\text{out}}\,\hat{\mathbf{U}}_A^{\text{in}} = \frac{1}{\sqrt{2}}\Big(\int_{\mathcal{M}_{\text{out}}<\epsilon_{\text{out}}} \cdots\Big)\Big(\int_{\mathcal{M}_{\text{in}}<\epsilon_{\text{in}}} \cdots\Big), \tag{3.43}$$

capturing "continuity through transformation" (diagonal) and "revolutionary" transitions (off-diagonal).

3. The Commutator Lensing Model: An Interference of Protocols

Lensing operators are algebraic *differences between protocols*, each protocol containing path–integral components. For the symmetric interferometer lensing,

$$\mathbf{U}_{\text{holo}}^{(\text{sym-com})} = \Big[\mathbf{U}_{\text{Had}},\, \mathbf{U}_{\text{ctrl}}\Big]\,\mathbf{U}_{\text{Had}}^{\dagger} = \Big(\mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}} - \mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{Had}}\Big)\mathbf{U}_{\text{Had}}^{\dagger}. \tag{3.44}$$

Substituting (3.40) (or (3.41)) into both terms makes explicit that the operator compares two meta-histories—"evolve then superpose" vs "superpose then evolve"—and isolates the algebraic twist due to non-commutativity. By (H4) equivalences (Definition 3.18), lensing is a control-basis/readout reparametrization on the same dual-register backbone (no new resources).

The Unity of Logic, Substance, and Locus The *Fourfold Dialectic Algebra* supplies the generative grammar; the *Gaiamiti* and *Tantrakyma* fields give it physical substance in $\mathcal{A}(\mathcal{C}_d)$; and the *PQS* furnishes the indivisible locus where logic and substance are unified, succinctly

$$\hat{\Omega}_{\vec{r}} := \mathring{\Lambda}_{\hat{\Theta}}^{\hat{\Phi}}.$$

Dynamics are encoded by path integrals over these fields; Holosymmetry then partitions the infinity of histories into two interfering families—*Coupled* and *Decoupled*—realizing the foundational duality in experimentally legible form via Born-valued effects.

The Commutator as an Interference of Protocols

Conceptually, the *commutator lensing* operator is not a single uninterrupted evolution; it compares two distinct *protocols* (remembering that the rightmost gate acts first):

1. *Protocol 1 (evolve then superpose):* $\mathbf{U}_{\mathrm{Had}}\mathbf{U}_{\mathrm{ctrl}}$.
2. *Protocol 2 (superpose then evolve):* $\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{Had}}$.

Their physical difference is isolated by

$$\mathbf{U}_{\mathrm{holo}}^{(\text{sym-com})} := \Big[\,\mathbf{U}_{\mathrm{Had}},\,\mathbf{U}_{\mathrm{ctrl}}\,\Big]\,\mathbf{U}_{\mathrm{Had}}^{\dagger}. \tag{3.45}$$

Decomposition note. Writing the controlled block as

$$\mathbf{U}_{\mathrm{ctrl}} = \mathbb{I}_c \otimes U_+ + Z_c \otimes U_-, \qquad U_\pm := \tfrac{1}{2}\big(\hat{\mathbf{U}}_A \pm \hat{\mathbf{U}}_B\big), \tag{3.46}$$

any control rotation $R \in \mathcal{U}(\mathcal{H}_c)$ obeys $[R, \mathbf{U}_{\mathrm{ctrl}}] = [R, Z_c] \otimes U_-$. Thus the commutator isolates exactly the *difference* piece: $\Delta\mathbf{U} = \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B = 2U_-$. By the (H4) equivalences (Definition 3.18), lensing is therefore just a control-basis/readout reparametrization on the same dual-register backbone.

Formal derivation and path-integral representation

1. Components.

1. Non-dynamical Hadamard on the control: $\mathbf{U}_{\mathrm{Had}} = H_c \otimes \mathbb{I}_{\mathrm{RR}}$, with $H_c = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$.
2. Controlled evolution (compact and path–integral forms):

$$\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle_c\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_A + |\mathbf{1}\rangle_c\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_B, \tag{3.47}$$

where

$$\hat{\mathbf{U}}_A := \int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\mathrm{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}, \qquad \hat{\mathbf{U}}_B := \int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\mathrm{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}. \tag{3.48}$$

2. Calculating the commutator. In the control basis, $\mathbf{U}_{\mathrm{Had}} \leftrightarrow \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{smallmatrix}\right)$ and $\mathbf{U}_{\mathrm{ctrl}} \leftrightarrow \left(\begin{smallmatrix} \hat{\mathbf{U}}_A & 0 \\ 0 & \hat{\mathbf{U}}_B \end{smallmatrix}\right)$. A short block-matrix multiplication gives

$$\Big[\,\mathbf{U}_{\mathrm{Had}},\,\mathbf{U}_{\mathrm{ctrl}}\,\Big] = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & -(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) \\ \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B & 0 \end{pmatrix}. \tag{3.49}$$

3. Applying the final gate. Since $\mathbf{U}_{\mathrm{Had}}^{\dagger} = \mathbf{U}_{\mathrm{Had}}$,

$$\mathbf{U}_{\mathrm{holo}}^{(\text{sym-com})} = \frac{1}{2}\begin{pmatrix} -(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) & (\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) \\ (\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) & (\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) \end{pmatrix}. \tag{3.50}$$

4. Path-integral "dissonance" operator. Define the *dissonance operator*

$$\Delta\mathbf{U} \;:=\; \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B \;=\; \Big(\int_{\mathcal{M}<\epsilon} - \int_{\mathcal{M}>\epsilon}\Big)\mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}, \tag{3.51}$$

so (3.50) becomes

$$\mathbf{U}_{\text{holo}}^{(\text{sym-com})} = \frac{1}{2}\begin{pmatrix} -\Delta\mathbf{U} & \Delta\mathbf{U} \\ \Delta\mathbf{U} & \Delta\mathbf{U} \end{pmatrix}. \tag{3.52}$$

Corollary 3.22 (Effect-level form for symmetric lensing)**.** *For initial control* $|\mathbf{a}\rangle_c$ *and readout* $|\mathbf{b}\rangle_c$ *in the computational basis, the channel Kraus block is* $K_{\mathbf{ba}} \in \{-\frac{1}{2}\Delta\mathbf{U},\ \frac{1}{2}\Delta\mathbf{U}\}$*. Hence every channel yields the same effect on* $\mathcal{H}_{\text{RR}}^{(2n)}$*:*

$$E_{\text{Holo}}^{(\mathbf{a}\nrightarrow\mathbf{b})} = K_{\mathbf{ba}}^{\dagger}K_{\mathbf{ba}} = \frac{1}{4}\,\Delta\mathbf{U}^{\dagger}\,\Delta\mathbf{U}, \qquad v_{\text{Holothesis}}(\rho) = \text{Tr}\Big(\rho\, E_{\text{Holo}}^{(\mathbf{a}\nrightarrow\mathbf{b})}\Big). \tag{3.53}$$

Thus lensing readouts measure the same "dissonance power'' irrespective of the computational channel; differences arise only from control-basis choices (cf. Definition 3.18).

Interpretation and operational note. Every entry of the lensing operator is proportional to the single object $\Delta\mathbf{U}$: the commutator acts as a *filter of differences*, canceling constructive (symmetric) contributions and isolating the algebraic "twist'' between the coupled and decoupled families. As written, $\mathbf{U}_{\text{holo}}^{(\text{sym-com})}$ need not be unitary by itself; experimentally it is accessed as a *difference of circuits* (e.g. control-sign tricks or linear-combination-of-unities methods), and its physical content is read out through effects and Born valuations defined in Definition 1.18. By the (H4) equivalences (Definition 3.18), lensing is a control-basis/readout reparametrization on the same dual-register backbone—no indefinite causal order is invoked.

The Asymmetric Lensing Operator

The defining operator isolates the non-commutativity between the controlled evolution and an arbitrary preparation, viewed from an arbitrary measurement basis:

$$\mathbf{U}_{\text{holo}}^{(\text{asym-com})} := [\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}]\;\mathbf{U}_{\text{read}}^{\dagger} = \Big(\mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{prep}} - \mathbf{U}_{\text{prep}}\mathbf{U}_{\text{ctrl}}\Big)\,\mathbf{U}_{\text{read}}^{\dagger},$$

where (as throughout) the rightmost gate acts first.

Formal derivation and path-integral representation

1. Components. Use general $SU(2)$ parametrizations for preparation and readout, and the path-integral–defined control:

$$\mathbf{U}_{\text{prep}} \leftrightarrow \begin{pmatrix} \alpha & -\beta^* \\ \beta & \alpha^* \end{pmatrix}, \quad \mathbf{U}_{\text{read}}^{\dagger} \leftrightarrow \begin{pmatrix} \gamma^* & \delta^* \\ -\delta & \gamma \end{pmatrix}, \quad \mathbf{U}_{\text{ctrl}} \leftrightarrow \begin{pmatrix} \hat{\mathbf{U}}_A & 0 \\ 0 & \hat{\mathbf{U}}_B \end{pmatrix},$$

with $|\alpha|^2+|\beta|^2 = |\gamma|^2+|\delta|^2 = 1$ (global phases immaterial). The path-integral forms are

$$\hat{\mathbf{U}}_A = \int_{\mathcal{M}<\epsilon}\mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{iS_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}, \qquad \hat{\mathbf{U}}_B = \int_{\mathcal{M}>\epsilon}\mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{iS_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]}.$$

2. Calculating the commutator.

$$\mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{prep}} \leftrightarrow \begin{pmatrix} \alpha\hat{\mathbf{U}}_A & -\beta^*\hat{\mathbf{U}}_A \\ \beta\hat{\mathbf{U}}_B & \alpha^*\hat{\mathbf{U}}_B \end{pmatrix}, \qquad \mathbf{U}_{\text{prep}}\mathbf{U}_{\text{ctrl}} \leftrightarrow \begin{pmatrix} \alpha\hat{\mathbf{U}}_A & -\beta^*\hat{\mathbf{U}}_B \\ \beta\hat{\mathbf{U}}_A & \alpha^*\hat{\mathbf{U}}_B \end{pmatrix}.$$

Taking the difference gives

$$[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] = \begin{pmatrix} 0 & -\beta^*(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) \\ -\beta(\hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B) & 0 \end{pmatrix}.$$

3. Applying the final gate. With $\Delta\mathbf{U} := \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B$,

$$\mathbf{U}_{\text{holo}}^{(\text{asym-com})} = \begin{pmatrix} 0 & -\beta^*\,\Delta\mathbf{U} \\ -\beta\,\Delta\mathbf{U} & 0 \end{pmatrix} \begin{pmatrix} \gamma^* & \delta^* \\ -\delta & \gamma \end{pmatrix} \tag{3.54}$$

$$= \begin{pmatrix} \delta\,\beta^*\,\Delta\mathbf{U} & -\gamma\,\beta^*\,\Delta\mathbf{U} \\ -\gamma^*\,\beta\,\Delta\mathbf{U} & -\delta^*\,\beta\,\Delta\mathbf{U} \end{pmatrix}. \tag{3.55}$$

4. Final path-integral form (dissonance factorization). Define the *dissonance operator*

$$\Delta\mathbf{U} := \hat{\mathbf{U}}_A - \hat{\mathbf{U}}_B = \left(\int_{\mathcal{M}<\epsilon} - \int_{\mathcal{M}>\epsilon}\right) \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{iS_{\text{total}}[\hat{\mathbf{\Phi}},\hat{\mathbf{\Theta}}]},$$

so the operator factors as

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{asym-com})} = \begin{pmatrix} \delta\beta^* & -\gamma\beta^* \\ -\gamma^*\beta & -\delta^*\beta \end{pmatrix} \otimes \Delta\mathbf{U}}.$$

Remark 3.23 (Effect-level corollary and visibility)**.** Let K_{ba} denote the block mapping control $|a\rangle_c \to |b\rangle_c$ in the computational basis. Then

$$K_{00} = \delta\beta^*\,\Delta\mathbf{U}, \quad K_{01} = -\gamma\beta^*\,\Delta\mathbf{U}, \quad K_{10} = -\gamma^*\beta\,\Delta\mathbf{U}, \quad K_{11} = -\delta^*\beta\,\Delta\mathbf{U},$$

and the corresponding effects on $\mathcal{H}_{\text{RR}}^{(2n)}$ are

$$E_{\text{Holo}}^{(a\to b)} = K_{ba}^\dagger K_{ba} = |c_{ba}|^2\,\Delta\mathbf{U}^\dagger\Delta\mathbf{U}, \quad c_{ba} \in \{\delta\beta^*, -\gamma\beta^*, -\gamma^*\beta, -\delta^*\beta\}.$$

Thus all channels measure the same "dissonance power'' $\Delta\mathbf{U}^\dagger\Delta\mathbf{U}$, scaled by the control coefficients. Two practical consequences:

- **Preparation visibility:** if $\beta = 0$ (prep an eigenstate of Z_c), then $[\mathbf{U}_{\text{ctrl}}, \mathbf{U}_{\text{prep}}] = 0$ and the lensing signal vanishes.
- **Path degeneracy:** if $\Delta\mathbf{U} = 0$ (identical paths), then all effects vanish: asymmetric lensing detects no twist.

By (H4) equivalences (Definition 3.18), varying (α, β) and (γ, δ) tomographically scans the same dual-register backbone; no indefinite causal order is involved. Readouts use Born valuations as in Definition 1.18.

Interpretation. Asymmetric lensing is a pure $\Delta\mathbf{U}$ probe with tunable projection set by the preparation/readout angles. It complements the symmetric case: the former yields *channel-dependent* weights $|c_{ba}|^2$ on the same operator $\Delta\mathbf{U}^\dagger\Delta\mathbf{U}$, enabling full tomographic control over the algebraic twist between the coupled and decoupled history classes.

The Path Scattering Protocol

The defining operator for this model describes a three-act process (rightmost gate acts first): *Evolve* → *Interfere* → *Re-evolve*

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} := \mathbf{U}_{\text{ctrl}} \cdot \mathbf{U}_{\text{Had}} \cdot \mathbf{U}_{\text{ctrl}}.$$

Here the registers evolve under $\mathbf{U}_{\text{ctrl}}$, are mixed by the Hadamard on the control, and then evolve again under the same controlled rule.

Formal derivation and path-integral representation

1. **Components.** Use the block forms

$$\mathbf{U}_{\text{Had}} \leftrightarrow \tfrac{1}{\sqrt{2}}\begin{pmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{pmatrix}, \qquad \mathbf{U}_{\text{ctrl}} \leftrightarrow \begin{pmatrix} \hat{\mathbf{U}}_A & 0 \\ 0 & \hat{\mathbf{U}}_B \end{pmatrix},$$

with

$$\hat{\mathbf{U}}_A = \int_{\mathcal{M}<\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\text{total}}}, \qquad \hat{\mathbf{U}}_B = \int_{\mathcal{M}>\epsilon} \mathcal{D}\hat{\mathbf{\Phi}}\,\mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\,S_{\text{total}}}.$$

2. **Calculating the operator product.**

$$\mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}} \leftrightarrow \tfrac{1}{\sqrt{2}}\begin{pmatrix} \hat{\mathbf{U}}_A & \hat{\mathbf{U}}_B \\ \hat{\mathbf{U}}_A & -\hat{\mathbf{U}}_B \end{pmatrix}, \quad \Rightarrow \quad \mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} \leftrightarrow \tfrac{1}{\sqrt{2}}\begin{pmatrix} \hat{\mathbf{U}}_A^2 & \hat{\mathbf{U}}_A\hat{\mathbf{U}}_B \\ \hat{\mathbf{U}}_B\hat{\mathbf{U}}_A & -\hat{\mathbf{U}}_B^2 \end{pmatrix}.$$

3. **Final path-integral form.** Substituting the constrained path-integral definitions for $\hat{\mathbf{U}}_A$ and $\hat{\mathbf{U}}_B$ gives

$$\boxed{\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \tfrac{1}{\sqrt{2}}\begin{pmatrix} \left(\int_{\mathcal{M}<\epsilon}\mathcal{D}\hat{\mathbf{\Phi}}\mathcal{D}\hat{\mathbf{\Theta}}\, e^{iS_{\text{total}}}\right)^2 & \left(\int_{\mathcal{M}<\epsilon}\cdots\right)\left(\int_{\mathcal{M}>\epsilon}\cdots\right) \\ \left(\int_{\mathcal{M}>\epsilon}\cdots\right)\left(\int_{\mathcal{M}<\epsilon}\cdots\right) & -\left(\int_{\mathcal{M}>\epsilon}\mathcal{D}\hat{\mathbf{\Phi}}\mathcal{D}\hat{\mathbf{\Theta}}\, e^{iS_{\text{total}}}\right)^2 \end{pmatrix};}$$

the products denote sequential composition of the two path-selected evolutions (*evolve, then evolve again*).

Channel blocks and valuations (drop-in). Writing the control-basis blocks as K_{ba} for $|a\rangle_c \to |b\rangle_c$,

$$K_{00} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A^2, \quad K_{01} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_A\hat{\mathbf{U}}_B, \quad K_{10} = \tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B\hat{\mathbf{U}}_A, \quad K_{11} = -\tfrac{1}{\sqrt{2}}\,\hat{\mathbf{U}}_B^2.$$

The corresponding holosymmetric effects on $\mathcal{H}_{\text{RR}}^{(2n)}$ are $E_{\text{Holo}}^{(a\to b)} = K_{ba}^\dagger K_{ba}$, so Born valuations follow directly via $\text{Tr}(\rho\, E_{\text{Holo}}^{(a\to b)})$ (cf. Definition 1.18).

Interpretation: a universe in dialogue with itself. Each matrix entry is a distinct feedback channel:

- *Diagonal* $\left(\propto \hat{\mathbf{U}}_A^2,\, -\hat{\mathbf{U}}_B^2\right)$: self-reinforcing loops—histories that remain in the same dynamical regime across the interference event (continuity/stability).
- *Off-diagonal* $\left(\propto \hat{\mathbf{U}}_A\hat{\mathbf{U}}_B,\, \hat{\mathbf{U}}_B\hat{\mathbf{U}}_A\right)$: regime-switching channels—histories that swap between coupled and decoupled evolution (transformation/novelty). The non-commutativity $[\hat{\mathbf{U}}_A, \hat{\mathbf{U}}_B]$ controls the asymmetry between the two off-diagonal amplitudes.

Thus path scattering models *reflexive* dynamics: past evolution conditions the interference, which conditions the future evolution.

Sanity checks and special cases.

1. **Identical paths** ($\hat{\mathbf{U}}_A = \hat{\mathbf{U}}_B = \hat{\mathbf{U}}$). Then $\mathbf{U}_{\text{ctrl}} = \mathbb{I}_c \otimes \hat{\mathbf{U}}$ and $\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = (\mathbf{U}_{\text{Had}} \otimes \hat{\mathbf{U}}^2)$. Off-diagonals become equal ($= \frac{1}{\sqrt{2}}\hat{\mathbf{U}}^2$); the protocol reduces to a trivial re-labelling on the control with a squared evolution on the registers.
2. **Inverse paths** ($\hat{\mathbf{U}}_B = \hat{\mathbf{U}}_A^\dagger$). Then $K_{00} = \frac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^2$, $K_{11} = -\frac{1}{\sqrt{2}}\mathbb{I}$; the two off-diagonals are $\frac{1}{\sqrt{2}}\hat{\mathbf{U}}_A\hat{\mathbf{U}}_A^\dagger = \frac{1}{\sqrt{2}}\mathbb{I}$ and its reverse, giving a clean split between "retain A", "retain B", and "swap" channels.
3. **Commuting paths** ($[\hat{\mathbf{U}}_A, \hat{\mathbf{U}}_B] = 0$). Off-diagonals are equal; any asymmetry in switching rates must then arise from state preparation, not algebraic twist.

Unitarity and consistency. If $\hat{\mathbf{U}}_A, \hat{\mathbf{U}}_B$ are unitary, then each factor in $\mathbf{U}_{\text{holo}}^{(\text{scatter,sym})} = \mathbf{U}_{\text{ctrl}}\mathbf{U}_{\text{Had}}\mathbf{U}_{\text{ctrl}}$ is unitary, so the overall protocol is unitary. This places the model squarely within standard circuit mechanics (no indefinite causal order). As noted above, the block identification shows this protocol is a special point of the Master Operator:

$$\mathbf{A} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A^2, \quad \mathbf{B} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_A\hat{\mathbf{U}}_B, \quad \mathbf{C} = \tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B\hat{\mathbf{U}}_A, \quad \mathbf{D} = -\tfrac{1}{\sqrt{2}}\hat{\mathbf{U}}_B^2,$$

with "diagonal symmetry up to a sign'' and generally unequal off-diagonals when the paths do not commute.

The Asymmetric Path Scattering Protocol

The defining operator describes a directed, three–act process (rightmost acts first): *Evolve under "in" rules → Interfere → Re-evolve under "out" rules*:

$$\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})} := \mathbf{U}_{\text{ctrl}}^{\text{out}}\, \mathbf{U}_{\text{Had}}\, \mathbf{U}_{\text{ctrl}}^{\text{in}}. \tag{3.56}$$

Here the "in" and "out" control operators may be built from different archetypal path operators, representing a structural change in the dynamical regime.

Formal derivation and path–integral representation

1. Components.

$$\mathbf{U}^{\text{in}}_{\text{ctrl}} \leftrightarrow \begin{pmatrix} \hat{\mathbf{U}}^{\text{in}}_A & 0 \\ 0 & \hat{\mathbf{U}}^{\text{in}}_B \end{pmatrix}, \qquad \mathbf{U}_{\text{Had}} \leftrightarrow \tfrac{1}{\sqrt{2}} \begin{pmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{pmatrix}, \qquad \mathbf{U}^{\text{out}}_{\text{ctrl}} \leftrightarrow \begin{pmatrix} \hat{\mathbf{U}}^{\text{out}}_A & 0 \\ 0 & \hat{\mathbf{U}}^{\text{out}}_B \end{pmatrix}.$$

2. Operator product. Multiplying from right to left,

$$\mathbf{U}^{(\text{scatter,asym})}_{\text{holo}} \leftrightarrow \tfrac{1}{\sqrt{2}} \begin{pmatrix} \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_A & \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_B \\ \hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_A & -\hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_B \end{pmatrix}. \tag{3.57}$$

3. Path–integral building blocks. Using (potentially) distinct modularity functionals/thresholds for the two epochs:

$$\boxed{\hat{\mathbf{U}}^{\text{in}}_A := \int_{\mathcal{M}_{\text{in}} < \epsilon_{\text{in}}} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,, \quad \hat{\mathbf{U}}^{\text{in}}_B := \int_{\mathcal{M}_{\text{in}} > \epsilon_{\text{in}}} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}} \tag{3.58}$$

$$\boxed{\hat{\mathbf{U}}^{\text{out}}_A := \int_{\mathcal{M}_{\text{out}} < \epsilon_{\text{out}}} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}\,, \quad \hat{\mathbf{U}}^{\text{out}}_B := \int_{\mathcal{M}_{\text{out}} > \epsilon_{\text{out}}} \mathcal{D}\hat{\mathbf{\Phi}}\, \mathcal{D}\hat{\mathbf{\Theta}}\; e^{\,i\, S_{\text{total}}[\hat{\mathbf{\Phi}}, \hat{\mathbf{\Theta}}]}} \tag{3.59}$$

(coupled A vs. decoupled B, as in the foundational definitions).

Channel blocks and effects (for valuations). Denote the control–basis blocks by K^{asym}_{ba} for the $|a\rangle_c \to |b\rangle_c$ channel. From (3.57):

$$\begin{aligned} K^{\text{asym}}_{00} &= \tfrac{1}{\sqrt{2}}\, \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_A, \quad K^{\text{asym}}_{01} = \tfrac{1}{\sqrt{2}}\, \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_B, \\ K^{\text{asym}}_{10} &= \tfrac{1}{\sqrt{2}}\, \hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_A, \quad K^{\text{asym}}_{11} = -\tfrac{1}{\sqrt{2}}\, \hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_B. \end{aligned}$$

The holosymmetric effects on $\mathcal{H}^{(2n)}_{\text{RR}}$ are $E^{(a \not\to b)}_{\text{Holo}} = (K^{\text{asym}}_{ba})^\dagger K^{\text{asym}}_{ba}$, so the Born valuations are $v(\rho; E) = \text{Tr}\big(\rho\, E^{(a \not\to b)}_{\text{Holo}}\big)$ (cf. Definition 1.18).

Interpretation: the mechanism of a learning universe. Each block is a complete, transformative history:

- *Continuity through transformation*: $K^{\text{asym}}_{00} \propto \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_A$ and $K^{\text{asym}}_{11} \propto -\hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_B$ describe persistence of the dynamical character across the interference boundary ($A \to A$, $B \to B$).
- *Regime change (revolution)*: $K^{\text{asym}}_{10} \propto \hat{\mathbf{U}}^{\text{out}}_B \hat{\mathbf{U}}^{\text{in}}_A$ and $K^{\text{asym}}_{01} \propto \hat{\mathbf{U}}^{\text{out}}_A \hat{\mathbf{U}}^{\text{in}}_B$ implement $A \to B$ and $B \to A$ transitions, with asymmetry governed by the algebra and the state of the registers.

Irreversibility is encoded by the mismatch between "in" and "out'' operators and thresholds—this protocol models how interference can *update* the effective laws.

Sanity checks and special cases.

1. **No regime change** ($\hat{\mathbf{U}}_{\bullet}^{\text{out}} = \hat{\mathbf{U}}_{\bullet}^{\text{in}}$). Then $\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})}$ reduces to the symmetric scatter form.

2. **Pure switcher** ($\hat{\mathbf{U}}_{A}^{\text{out}} = \hat{\mathbf{U}}_{B}^{\text{out}}$ or $\hat{\mathbf{U}}_{A}^{\text{in}} = \hat{\mathbf{U}}_{B}^{\text{in}}$). One off–diagonal channel can dominate; use this to design targeted $A \leftrightarrow B$ conversions.

3. **Unitarity.** If each $\hat{\mathbf{U}}_{A/B}^{\text{in/out}}$ is unitary, then $\mathbf{U}_{\text{ctrl}}^{\text{in/out}}$ and $\mathbf{U}_{\text{Had}}$ are unitary, hence $\mathbf{U}_{\text{holo}}^{(\text{scatter,asym})}$ is unitary. No indefinite causal order is invoked.

Part II

The Continuum

Chapter 4

Modal Fibres and Emergent Hilbert Spaces

4.1 Structure of Emergent Hilbert Spaces

4.1.1 Twofold Inter-Modal Correlator of Primordial Quantum Singularities

Definition 4.1 (Twofold Inter-Modal Correlator of Primordial Quantum Singularities)**.** Fix a PQS locus $\mathfrak{B}_x$. The Symmetry–Antisymmetry (Twofold) sector

$$\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)} := \mathrm{span}\{\, |\mathring{\mathbf{0}}\rangle_x,\, |\mathring{\mathbf{1}}\rangle_x \,\}$$

is the $(0,1)$-slice of the Fourfold modal fibre introduced in the Fourfold Dialectic setting (Chapter 1; ringed kets and the prism correspondence Sym $\leftrightarrow$ Th, AntiSym $\leftrightarrow$ AntiTh, cf. Definitions 1.16 and 1.23 and Lemma 1.20), and realized concretely in Chapter 2 as the Twofold subspace with the $(0,1)$ basis and Born-effect semantics (Definition 1.18 and the $(0,1)$ realisation therein).

Let $\mathcal{U}(x \leftarrow x';\gamma)$ denote the parallel transporter generated by the emergent connection $\mathcal{A}$ along a path $\gamma \subset \mathcal{X}_q$ (Chapter 4; eqs. (4.11), (4.14) and (4.16)). For the Fourfold selection operators $\hat{\mathcal{F}}_\alpha(\cdot)$ (Chapter 1; transported to fibres via the bridge congruence Φ, Lemma 1.20), define the restricted components

$$\hat{G}^{\alpha\beta}_{(0,1)}(x,x') := \hat{\mathcal{F}}^\dagger_\alpha(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x') \qquad (\alpha,\beta \in \{0,1\}),$$

i.e. the $(0,1)$-block of the Fourfold correlator kernel (Chapter 4; $\hat{\mathbf{G}}_\Lambda$ and its block structure $\{0,1,p,s\}$). Writing

$$|\psi_1\rangle_x = c^{(1)}_0|\mathring{\mathbf{0}}\rangle_x + c^{(1)}_1|\mathring{\mathbf{1}}\rangle_x, \quad |\psi_2\rangle_{x'} = c^{(2)}_0|\mathring{\mathbf{0}}\rangle_{x'} + c^{(2)}_1|\mathring{\mathbf{1}}\rangle_{x'},$$

and $c^{(j)} = (c^{(j)}_0, c^{(j)}_1)^\top$, set the Twofold Inter-Modal Correlator to be the operator-valued, sesquilinear kernel

$$\begin{aligned} \hat{G}_{(0,1)}(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2] &:= \left(c^{(1)}\right)^\dagger \hat{\mathbf{G}}_{(0,1)}(x,x')\,c^{(2)}, \\ \hat{\mathbf{G}}_{(0,1)}(x,x') &= \left[\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\right]_{\alpha,\beta\in\{0,1\}}. \end{aligned} \tag{4.1}$$

Here the action of $\hat{\mathcal{F}}_\alpha$ on modal states is the operator realisation of the corner selectors of Chapter 1 (Fourfold *-algebra; Definition 1.16), and $\mathcal{U}$ is the path-ordered exponential of $\mathcal{A}$ (Chapter 4; eq. (4.11)). In interferometric realisations with a control register, $\hat{\mathcal{F}}_\alpha$ arise as the corner-conditioned blocks of the master holosymmetric operator of Chapter 3 (Section 3.8.3 and Corollary 3.21), but the present definition is representation-agnostic.

Basic properties of the twofold inter-modal correlator

Proposition 4.2 (Sesquilinearity)**.** *The map $(\psi_1^*, \psi_2) \mapsto \hat{G}_{(0,1)}[\psi_1^*, \psi_2]$ is conjugate-linear in the first slot and linear in the second:*

$$\hat{G}_{(0,1)}[\lambda\psi_1^* + \mu\phi_1^*, \psi_2] = \overline{\lambda}\,\hat{G}_{(0,1)}[\psi_1^*, \psi_2] + \overline{\mu}\,\hat{G}_{(0,1)}[\phi_1^*, \psi_2],$$
$$\hat{G}_{(0,1)}[\psi_1^*, \lambda\psi_2 + \mu\phi_2] = \lambda\,\hat{G}_{(0,1)}[\psi_1^*, \psi_2] + \mu\,\hat{G}_{(0,1)}[\psi_1^*, \phi_2].$$

Proof. Let $\psi_1, \phi_1 \in \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$ and $\psi_2, \phi_2 \in \mathcal{H}^{(\mathfrak{B}_{x'})}_{\mathrm{mod}\,(0,1)}$. Write the coefficient maps in the fixed $(0,1)$-basis

$$\mathcal{C}_x : \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)} \to \mathbb{C}^2, \qquad \mathcal{C}_{x'} : \mathcal{H}^{(\mathfrak{B}_{x'})}_{\mathrm{mod}\,(0,1)} \to \mathbb{C}^2,$$

so that $c^{(1)} := \mathcal{C}_x(\psi_1)$, $d^{(1)} := \mathcal{C}_x(\phi_1)$, $c^{(2)} := \mathcal{C}_{x'}(\psi_2)$, $d^{(2)} := \mathcal{C}_{x'}(\phi_2)$. By definition of the Twofold correlator (cf. (4.1)),

$$\hat{G}_{(0,1)}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] = (c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}(x, x')\, c^{(2)},$$

where $\hat{\mathbf{G}}_{(0,1)}(x, x') \in \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is fixed by (x, x').

(1) Conjugate homogeneity in the first slot. For $\lambda, \mu \in \mathbb{C}$,

$$\begin{aligned}
\hat{G}_{(0,1)}[(\lambda\psi_1 + \mu\phi_1)^*, \psi_2] &= \big(\mathcal{C}_x(\lambda\psi_1 + \mu\phi_1)\big)^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, c^{(2)} \\
&= (\lambda c^{(1)} + \mu d^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, c^{(2)} \quad \text{(linearity of } \mathcal{C}_x\text{)} \\
&= \overline{\lambda}\,(c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, c^{(2)} \;+\; \overline{\mu}\,(d^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, c^{(2)} \\
&= \overline{\lambda}\,\hat{G}_{(0,1)}[\psi_1^*, \psi_2] \;+\; \overline{\mu}\,\hat{G}_{(0,1)}[\phi_1^*, \psi_2].
\end{aligned}$$

(2) Additivity in the first slot. Setting $\lambda = \mu = 1$ in the previous computation gives

$$\hat{G}_{(0,1)}[(\psi_1 + \phi_1)^*, \psi_2] = \hat{G}_{(0,1)}[\psi_1^*, \psi_2] + \hat{G}_{(0,1)}[\phi_1^*, \psi_2].$$

(3) Linearity in the second slot (homogeneity and additivity). For $\lambda, \mu \in \mathbb{C}$,

$$\begin{aligned}
\hat{G}_{(0,1)}[\psi_1^*, \lambda\psi_2 + \mu\phi_2] &= (c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, \mathcal{C}_{x'}(\lambda\psi_2 + \mu\phi_2) \\
&= (c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, (\lambda c^{(2)} + \mu d^{(2)}) \quad \text{(linearity of } \mathcal{C}_{x'}\text{)} \\
&= \lambda\,(c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, c^{(2)} \;+\; \mu\,(c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, d^{(2)} \\
&= \lambda\,\hat{G}_{(0,1)}[\psi_1^*, \psi_2] \;+\; \mu\,\hat{G}_{(0,1)}[\psi_1^*, \phi_2].
\end{aligned}$$

Items (1)–(3) together establish conjugate-linearity in the first argument and linearity in the second. All equalities hold in the operator space $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$, and no further properties of $\hat{\mathbf{G}}_{(0,1)}$ are required beyond its being fixed for (x, x'). □

Proposition 4.3 (Hermitian symmetry)**.** *For all* $\alpha, \beta \in \{0,1\}$,

$$\left(\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\right)^\dagger = \hat{G}^{\beta\alpha}_{(0,1)}(x',x),$$

and thus

$$\hat{G}_{(0,1)}(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]^\dagger = \hat{G}_{(0,1)}(\mathfrak{B}_{x'},\mathfrak{B}_x)[\psi_2^*,\psi_1].$$

Proof. Step 0: Adjointability and domain. By construction, $\hat{\mathcal{F}}_\alpha(x)$ are bounded (or at least adjointable) operators and $\mathcal{U}(x \leftarrow x';\gamma)$ is unitary as a parallel transport generated by the connection $\mathcal{A}$; hence all products below are adjointable with adjoints in $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$.

Step 1: Component-level symmetry. By definition,

$$\hat{G}^{\alpha\beta}_{(0,1)}(x,x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x').$$

Taking adjoints and using $(ABC)^\dagger = C^\dagger B^\dagger A^\dagger$, we obtain

$$\left(\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\right)^\dagger = \hat{\mathcal{F}}^\dagger_\beta(x')\left(\mathcal{U}(x \leftarrow x';\gamma)\right)^\dagger \hat{\mathcal{F}}_\alpha(x).$$

Unitarity and the path-reversal/composition identities for transport (Chapter 4; $\mathcal{U}^\dagger = \mathcal{U}^{-1}$ and $\mathcal{U}(x \leftarrow x';\gamma)^{-1} = \mathcal{U}(x' \leftarrow x;\gamma^{-1})$, cf. eq. (4.14)) give

$$\left(\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\right)^\dagger = \hat{\mathcal{F}}^\dagger_\beta(x')\,\mathcal{U}(x' \leftarrow x;\gamma^{-1})\,\hat{\mathcal{F}}_\alpha(x) = \hat{G}^{\beta\alpha}_{(0,1)}(x',x),$$

which is the desired component identity.

Step 2: Kernel-level symmetry. Write the coefficient expansions in the fixed $(0,1)$-basis:

$$|\psi_1\rangle_x = \sum_{\alpha\in\{0,1\}} c^{(1)}_\alpha\, |\overset{\circ}{\alpha}\rangle_x, \qquad |\psi_2\rangle_{x'} = \sum_{\beta\in\{0,1\}} c^{(2)}_\beta\, |\overset{\circ}{\beta}\rangle_{x'}.$$

Then (cf. (4.1))

$$\hat{G}_{(0,1)}(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2] = \sum_{\alpha,\beta} \overline{c^{(1)}_\alpha}\; \hat{G}^{\alpha\beta}_{(0,1)}(x,x')\; c^{(2)}_\beta.$$

Taking adjoints and using linearity of the adjoint together with the scalar rule $(\overline{z}\,A\,w)^\dagger = \overline{w}\,A^\dagger z$ for $z, w \in \mathbb{C}$, we get

$$\left(\hat{G}_{(0,1)}[\psi_1^*,\psi_2]\right)^\dagger = \sum_{\alpha,\beta} \overline{c^{(2)}_\beta}\; \left(\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\right)^\dagger c^{(1)}_\alpha.$$

Applying Step 1 to the component adjoint yields

$$\left(\hat{G}_{(0,1)}[\psi_1^*,\psi_2]\right)^\dagger = \sum_{\alpha,\beta} \overline{c^{(2)}_\beta}\; \hat{G}^{\beta\alpha}_{(0,1)}(x',x)\; c^{(1)}_\alpha.$$

Relabelling the dummy indices $\alpha \leftrightarrow \beta$ gives

$$\left(\hat{G}_{(0,1)}[\psi_1^*,\psi_2]\right)^\dagger = \sum_{\alpha,\beta} \overline{c^{(2)}_\alpha}\; \hat{G}^{\alpha\beta}_{(0,1)}(x',x)\; c^{(1)}_\beta = \hat{G}_{(0,1)}(\mathfrak{B}_{x'},\mathfrak{B}_x)[\psi_2^*,\psi_1],$$

which proves the second identity. □

Proposition 4.4 (Gauge covariance)**.** *Under local frame changes $g(\cdot)$ (Chapter 4; eq. (4.16)), the fields transform as*

$$\hat{\mathcal{F}}_\alpha(x) \mapsto g(x)\hat{\mathcal{F}}_\alpha(x), \qquad \mathcal{U}(x \leftarrow x';\gamma) \mapsto g(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,g(x')^\dagger,$$

and the block obeys

$$\hat{\mathbf{G}}_{(0,1)}(x,x') \mapsto g(x)\,\hat{\mathbf{G}}_{(0,1)}(x,x')\,g(x')^\dagger.$$

Consequently, any Born expectation in a gauge-covariant state (Chapter 1; Definition 1.18) is gauge-invariant.

Proof. Step 0: Adjoints and transport. From the stated transformation of $\hat{\mathcal{F}}_\alpha(x)$, taking adjoints yields $\hat{\mathcal{F}}^\dagger_\alpha(x) \mapsto \hat{\mathcal{F}}^\dagger_\alpha(x)\,g(x)^\dagger$. For transport, $\mathcal{U} \mapsto g(x)\mathcal{U}g(x')^\dagger$ (Chapter 4; eq. (4.16)).

Step 1: Component-level transformation. By definition,

$$\hat{G}^{\alpha\beta}_{(0,1)}(x,x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x').$$

After a gauge change,

$$\begin{aligned}\Big(\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\Big)' &= \Big(\hat{\mathcal{F}}^\dagger_\alpha(x)\,g(x)^\dagger\Big)\Big(g(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,g(x')^\dagger\Big)\Big(g(x')\,\hat{\mathcal{F}}_\beta(x')\Big)\\ &= \hat{\mathcal{F}}^\dagger_\alpha(x)\,\underbrace{g(x)^\dagger g(x)}_{=\mathbb{I}}\,\mathcal{U}(x \leftarrow x';\gamma)\,\underbrace{g(x')^\dagger g(x')}_{=\mathbb{I}}\,\hat{\mathcal{F}}_\beta(x')\\ &= \hat{G}^{\alpha\beta}_{(0,1)}(x,x').\end{aligned}$$

Thus each *component* is gauge-*invariant* as an operator in $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$.

Step 2: Block-level covariance as change of frames at the endpoints. Arrange the components into the 2×2 block $\hat{\mathbf{G}}_{(0,1)}(x,x') = \big[\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\big]_{\alpha,\beta\in\{0,1\}}$. This block is naturally a morphism from the x'-anchored frame to the x-anchored frame. Under a change of local frames at the endpoints by $g(x)$ and $g(x')$, the *coordinate* representation of a fixed morphism transforms by left/right action:

$$\hat{\mathbf{G}}_{(0,1)}(x,x') \;\longmapsto\; g(x)\,\hat{\mathbf{G}}_{(0,1)}(x,x')\,g(x')^\dagger.$$

This expresses the usual functorial behaviour of a bi-anchored kernel under basis change. It is compatible with Step 1: the underlying operator is invariant, while its matrix representatives in the moved frames are related by conjugation at the endpoints.

Step 3: Kernel-level covariance for arbitrary inputs. Let $|\psi_1\rangle_x = \sum_\alpha c^{(1)}_\alpha |\overset{\circ}{\alpha}\rangle_x$, $|\psi_2\rangle_{x'} = \sum_\beta c^{(2)}_\beta |\overset{\circ}{\beta}\rangle_{x'}$, and $c^{(j)} = (c^{(j)}_0, c^{(j)}_1)^\top$. Then (cf. (4.1))

$$\hat{G}_{(0,1)}[\psi_1^*,\psi_2] = (c^{(1)})^\dagger\,\hat{\mathbf{G}}_{(0,1)}(x,x')\,c^{(2)}.$$

Under frame changes, the coefficient vectors transform contragrediently: $c^{(1)} \mapsto (c^{(1)})' = g(x)\,c^{(1)}$ and $c^{(2)} \mapsto (c^{(2)})' = g(x')\,c^{(2)}$ (i.e., their components are taken in the moved frames). Hence

$$\begin{aligned}\Big(\hat{G}_{(0,1)}[\psi_1^*,\psi_2]\Big)' &= \Big((c^{(1)})'\Big)^\dagger\,\Big(\hat{\mathbf{G}}_{(0,1)}\Big)'\,(c^{(2)})'\\ &= (c^{(1)})^\dagger g(x)^\dagger\,\Big(g(x)\hat{\mathbf{G}}_{(0,1)}g(x')^\dagger\Big)\,g(x')\,c^{(2)}\\ &= (c^{(1)})^\dagger\,\hat{\mathbf{G}}_{(0,1)}\,c^{(2)} = \hat{G}_{(0,1)}[\psi_1^*,\psi_2],\end{aligned}$$

so the *kernel value* is invariant as an operator in $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$.

Step 4: Gauge invariance of Born expectations. Let ρ be a (gauge-covariant) state on $\mathcal{H}_{\mathrm{em}}$. If $\rho \mapsto \rho' = g(x)\,\rho\,g(x)^\dagger$ (or, more generally, the appropriate anchor is used), then by the cyclicity of the trace and the block transformation in Step 2,

$$\mathrm{Tr}\Big(\rho\,\hat{\mathbf{G}}_{(0,1)}(x,x')\Big) = \mathrm{Tr}\Big(g(x)\rho g(x)^\dagger\; g(x)\hat{\mathbf{G}}_{(0,1)}(x,x')g(x')^\dagger\Big) = \mathrm{Tr}\Big(\rho'\,\hat{\mathbf{G}}'_{(0,1)}(x,x')\Big),$$

and likewise for vector states $|\Psi\rangle$ with $|\Psi\rangle \mapsto |\Psi'\rangle = g(\cdot)|\Psi\rangle$. Therefore, Born expectations (Chapter 1; Definition 1.18) are gauge-invariant.

The proposition follows: components are gauge-invariant, their block transforms covariantly under endpoint frame changes, and all Born valuations are invariant. □

Alternative proof (fibre-bundle notation). Let $\pi : \mathscr{H}_{\mathrm{mod}} \to \mathcal{X}_q$ be the modal Hilbert bundle of Chapter 4 and let $\mathscr{H}_{(0,1)} \subset \mathscr{H}_{\mathrm{mod}}$ be its Twofold subbundle with fibres $\pi^{-1}(x) = \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$. Write $P \to \mathcal{X}_q$ for the principal unitary frame bundle of $\mathscr{H}_{(0,1)}$ with structure group $G_{(0,1)} \subseteq \mathrm{U}(2)$. A (local) gauge transformation is a vertical bundle automorphism of P whose representative in a trivialisation $U \subset \mathcal{X}_q$ is a smooth map $g : U \to G_{(0,1)}$.

Selectors as an associated bundle morphism. Define the bundle map

$$\mathcal{F} :\ \mathscr{H}_{(0,1)} \longrightarrow \underline{\mathcal{B}(\mathcal{H}_{\mathrm{em}})} \qquad (x,v) \mapsto \hat{\mathcal{F}}_x(v) := \sum_{\alpha\in\{0,1\}} v_\alpha\,\hat{\mathcal{F}}_\alpha(x),$$

where $v = \sum_\alpha v_\alpha\,|\overset{\circ}{\alpha}\rangle_x$ in a local frame and $\underline{\mathcal{B}(\mathcal{H}_{\mathrm{em}})} = \mathcal{X}_q \times \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is the trivial bundle. By the Chapter 1 transformation law, $\hat{\mathcal{F}}_\alpha(x) \mapsto g(x)\hat{\mathcal{F}}_\alpha(x)$, hence $\mathcal{F}$ is $G_{(0,1)}$-equivariant:

$$\mathcal{F}_{x\cdot g}\Big(v\cdot g^{-1}(x)\Big) \;=\; g(x)\,\mathcal{F}_x(v).$$

Consequently, the adjoint map $\mathcal{F}_x^\dagger$ (with the adjoint taken in $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$) transforms as $\mathcal{F}_x^\dagger \mapsto \mathcal{F}_x^\dagger\,g(x)^\dagger$.

Transport as a bundle morphism. Let $\mathcal{A}$ be the connection of Chapter 4 and let $\mathcal{U}(x \leftarrow x';\gamma) : \mathscr{H}_{(0,1),x'} \to \mathscr{H}_{(0,1),x}$ be the parallel transport along γ (eq. (4.11)). Under the gauge change g, its local representative transforms as

$$\mathcal{U}(x\leftarrow x';\gamma) \;\longmapsto\; g(x)\,\mathcal{U}(x\leftarrow x';\gamma)\,g(x')^\dagger \qquad \text{(Chapter 4; eq. (4.16))}.$$

The correlator as a section of a Hom-bundle. Define the bi-anchored bundle morphism

$$\hat{\mathbf{G}}_{(0,1)}(x,x') \;:=\; \mathcal{F}_x^\dagger \circ \mathcal{U}(x\leftarrow x';\gamma) \circ \mathcal{F}_{x'} \;\in\; \mathrm{Hom}\Big(\mathscr{H}_{(0,1),x'}, \mathscr{H}_{(0,1),x}\Big) \otimes \mathcal{B}(\mathcal{H}_{\mathrm{em}}).$$

Using the equivariance of $\mathcal{F}$ and the gauge law for $\mathcal{U}$, we obtain

$$\hat{\mathbf{G}}_{(0,1)}(x,x') \;\longmapsto\; \Big(\mathcal{F}_x^\dagger g(x)^\dagger\Big)\Big(g(x)\mathcal{U}g(x')^\dagger\Big)\Big(g(x')\mathcal{F}_{x'}\Big) \;=\; g(x)\,\hat{\mathbf{G}}_{(0,1)}(x,x')\,g(x')^\dagger,$$

which is exactly the announced two-sided covariance at the endpoints.

Coordinate-free kernel and invariance. Given $\psi_1 \in \mathscr{H}_{(0,1),x}$ and $\psi_2 \in \mathscr{H}_{(0,1),x'}$, define the operator-valued kernel

$$\hat{G}_{(0,1)}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \;:=\; \hat{\mathbf{G}}_{(0,1)}(x,x')\Big(\psi_2\Big) \;\text{ contracted with }\; \psi_1^*,$$

which in a local frame reproduces $(c^{(1)})^\dagger\, \hat{\mathbf{G}}_{(0,1)}(x,x')\, c^{(2)}$ (cf. (4.1)). Under a gauge change, vectors ψ_1, ψ_2 co-transform as $\psi_1 \mapsto g(x)\psi_1$, $\psi_2 \mapsto g(x')\psi_2$, whence

$$\begin{aligned}\hat{G}'_{(0,1)}[\psi_1'^*, \psi_2'] &= \big(\psi_1'\big)^\dagger\, \hat{\mathbf{G}}'_{(0,1)}\, \psi_2' = \psi_1^\dagger g(x)^\dagger\, \Big(g(x)\hat{\mathbf{G}}_{(0,1)}g(x')^\dagger\Big)\, g(x')\psi_2 = \psi_1^\dagger\, \hat{\mathbf{G}}_{(0,1)}\, \psi_2 \\ &= \hat{G}_{(0,1)}[\psi_1^*, \psi_2],\end{aligned}$$

so the operator-valued kernel is gauge *invariant* for co-transforming inputs.

Born expectations are gauge-invariant. For any state ρ on $\mathcal{H}_{\mathrm{em}}$ (Chapter 1; Definition 1.18), let $\rho \mapsto \rho' = g(x)\rho g(x)^\dagger$ be the induced transformation at the x-anchor. Then, using the block covariance and cyclicity of trace,

$$\mathrm{Tr}\Big(\rho\, \hat{\mathbf{G}}_{(0,1)}(x,x')\Big) = \mathrm{Tr}\Big(g(x)\rho g(x)^\dagger\; g(x)\hat{\mathbf{G}}_{(0,1)}(x,x')g(x')^\dagger\Big) = \mathrm{Tr}\Big(\rho'\, \hat{\mathbf{G}}'_{(0,1)}(x,x')\Big).$$

Hence all Born valuations are gauge-invariant.

This establishes the fibre-bundle form of gauge covariance: $\hat{\mathbf{G}}_{(0,1)}$ is a section of $\mathrm{Hom}(\mathscr{H}_{(0,1),x'}, \mathscr{H}_{(0,1),x}) \otimes \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ with the natural $(g(x), g(x'))$-action, and both kernel values and expectations are invariant under gauge changes. □

Proposition 4.5 (Boundedness)**.** *If each $\hat{\mathcal{F}}_\alpha(x)$ is bounded and $\|\mathcal{U}\| = 1$, then for any ψ_1, ψ_2*

$$\Big\|\hat{G}_{(0,1)}[\psi_1^*, \psi_2]\Big\| \;\le\; \|c^{(1)}\|\, \|c^{(2)}\| \max_{\alpha,\beta\in\{0,1\}} \Big\|\hat{\mathcal{F}}_\alpha(x)\Big\|\, \Big\|\hat{\mathcal{F}}_\beta(x')\Big\|.$$

Proof. **Coefficient expansions.** In the fixed $(0,1)$-basis, write

$$\begin{aligned}|\psi_1\rangle_x &= c_0^{(1)}\, |\mathring{\mathbf{0}}\rangle_x + c_1^{(1)}\, |\mathring{\mathbf{1}}\rangle_x, \\ |\psi_2\rangle_{x'} &= c_0^{(2)}\, |\mathring{\mathbf{0}}\rangle_{x'} + c_1^{(2)}\, |\mathring{\mathbf{1}}\rangle_{x'}.\end{aligned} \tag{4.2}$$

Set $c^{(1)} := (c_0^{(1)}, c_1^{(1)})^\top$ and $c^{(2)} := (c_0^{(2)}, c_1^{(2)})^\top$. Recall (cf. (4.1)) that

$$\hat{G}_{(0,1)}[\psi_1^*, \psi_2] = \sum_{\alpha,\beta\in\{0,1\}} \overline{c_\alpha^{(1)}}\, \hat{G}^{\alpha\beta}_{(0,1)}(x,x')\, c_\beta^{(2)}, \qquad \hat{G}^{\alpha\beta}_{(0,1)}(x,x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x'). \tag{4.3}$$

Step 1: Component bounds. By submultiplicativity of the operator norm and $\|\mathcal{U}\| = 1$,

$$\Big\|\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\Big\| \;\le\; \Big\|\hat{\mathcal{F}}_\alpha(x)\Big\|\, \Big\|\hat{\mathcal{F}}_\beta(x')\Big\| \;\le\; K, \quad K := \max_{\alpha,\beta\in\{0,1\}} \Big\|\hat{\mathcal{F}}_\alpha(x)\Big\|\, \Big\|\hat{\mathcal{F}}_\beta(x')\Big\|.$$

Step 2: Triangle inequality and scalar extraction. Using the triangle inequality in $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$,

$$\Big\|\hat{G}_{(0,1)}[\psi_1^*, \psi_2]\Big\| \;\le\; \sum_{\alpha,\beta} \Big|c_\alpha^{(1)}\Big|\, \Big\|\hat{G}^{\alpha\beta}_{(0,1)}(x,x')\Big\|\, \Big|c_\beta^{(2)}\Big| \;\le\; K \sum_{\alpha,\beta} \Big|c_\alpha^{(1)}\Big|\, \Big|c_\beta^{(2)}\Big|.$$

Step 3: Bounding the scalar double sum. Factor the double sum and apply Hölder:

$$\sum_{\alpha,\beta} \left|c_\alpha^{(1)}\right| \left|c_\beta^{(2)}\right| = \Big(\sum_\alpha \left|c_\alpha^{(1)}\right|\Big)\Big(\sum_\beta \left|c_\beta^{(2)}\right|\Big) = \|c^{(1)}\|_1 \, \|c^{(2)}\|_1.$$

Hence

$$\left\|\hat{G}_{(0,1)}[\psi_1^*, \psi_2]\right\| \;\le\; K \, \|c^{(1)}\|_1 \, \|c^{(2)}\|_1.$$

Step 4: Relating ℓ^1 and ℓ^2 norms on $\mathbb{C}^2$. On $\mathbb{C}^2$, $\|v\|_1 \le \sqrt{2}\,\|v\|_2$. Therefore,

$$\left\|\hat{G}_{(0,1)}[\psi_1^*, \psi_2]\right\| \;\le\; K \, (\sqrt{2}\,\|c^{(1)}\|_2)\,(\sqrt{2}\,\|c^{(2)}\|_2) \;=\; 2K \, \|c^{(1)}\| \, \|c^{(2)}\|,$$

where $\|\cdot\|$ denotes the Euclidean norm on $\mathbb{C}^2$.

Step 5: Tightening under the coefficient-norm convention. If, as is often convenient in this context, one measures coefficient vectors in the ℓ^1-norm ($\|\cdot\| := \|\cdot\|_1$ for $\mathbb{C}^2$), then Step 3 already yields

$$\left\|\hat{G}_{(0,1)}[\psi_1^*, \psi_2]\right\| \;\le\; \|c^{(1)}\| \, \|c^{(2)}\| \, \max_{\alpha,\beta} \left\|\hat{\mathcal{F}}_\alpha(x)\right\| \left\|\hat{\mathcal{F}}_\beta(x')\right\|.$$

If instead the Euclidean norm is preferred on $\mathbb{C}^2$, the same inequality holds with a universal constant factor 2 multiplying the right-hand side, as shown above.

Combining the steps gives the stated boundedness estimate, with the precise constant determined by the coefficient-norm convention on $\mathbb{C}^2$. □

Remark 4.6 (Sharpness and conventions)**.** For 2×2 blocks, the universal constant 2 in the ℓ^2-based bound is optimal in general (e.g. for a block with identical entries). When downstream sections use the Euclidean norm on coefficients, one may record the estimate with the explicit factor 2; when an ℓ^1 convention is adopted for coefficient vectors, the bound appears exactly as in the proposition's display. Both conventions are compatible with Chapters 1–4 and leave the operator-side assumptions unchanged.

Proposition 4.7 (Restriction of the Fourfold correlator)**.** *Let*

$$\hat{\mathbf{G}}_\Lambda(x, x') := \left[\hat{G}_\Lambda^{\alpha\beta}(x, x')\right]_{\alpha,\beta\in\{0,1,p,s\}}, \tag{4.4}$$

be the Fourfold inter-modal correlator of Chapter 4, constructed from the Fourfold modal algebra of Chapter 1 via the bridge Φ (Lemma 1.20) and the transport $\mathcal{U}$ (eq. (4.11)). Then

$$\hat{\mathbf{G}}_{(0,1)}(x, x') \text{ is precisely the top-left } 2 \times 2 \text{ block of } \hat{\mathbf{G}}_\Lambda(x, x').$$

Proof. By definition, $\hat{\mathcal{F}}_\alpha$ with $\alpha \in \{0, 1, p, s\}$ label the Fourfold corner selectors (Chapter 1; Definition 1.16). The restriction $\alpha, \beta \in \{0, 1\}$ selects the Twofold sub-family of components, which assemble into the stated block. □

Remark 4.8. The Twofold correlator captures only Symmetry–Antisymmetry relations. Parasymmetric and Holosymmetric phenomena involve the full Fourfold correlator and its off-diagonal blocks that mix $\{0, 1\}$ with $\{p, s\}$.

4.1.2 The Fourfold Inter-Modal Correlator of Quantum Singularities

The *Fourfold Inter-Modal Correlator* is the central operator-valued two-point kernel encoding quantum–relational dynamics in the IQR. It assembles, in a single 4×4 block structure, the gauge-covariant correlations among the four internal dialectic modes—*Symmetry*, *Antisymmetry*, *Parasymmetry*, and *Holosymmetry*—for any two Primordial Quantum Singularities (PQS) $\mathfrak{B}_x, \mathfrak{B}_{x'}$. Algebraically, it is the relational kernel compatible with the *Fourfold Dialectic Algebra* (Chapter 1; cf. Definitions 1.16 and 1.23 and Lemma 1.20), with Born-valued semantics for effect readouts (Definition 1.18), and with the corner–mode identifications Sym $\leftrightarrow$ Th, AntiSym $\leftrightarrow$ AntiTh, ParaSym $\leftrightarrow$ SynTh, HoloSym $\leftrightarrow$ HoloTh (cf. Chapter 1: Sections 1.2.1 to 1.2.4). Operationally, it underwrites inter-PQS interference and holomodal entanglement via the holosymmetric interferometers of Chapter 3 (cf. Sections 3.1, 3.1.1 and 3.1.5), where its control-basis readouts appear as Holothesis effects derived from the master holosymmetric operator (Section 3.8.3 and Corollary 3.21). The Twofold $(0,1)$ restriction of this correlator interfaces with the concrete $(0,1)$-sector realisation and parasymmetric/dissonant projectors developed in Chapter 2 (Twofold slice and local operational tests), ensuring full compatibility of the correlator with the established modal semantics and experiments of Chapters 1–3.

Definition 4.9 (Fourfold Inter-Modal Correlator and Emergent Realization)**.** Let $\mathfrak{M} := \{\mathring{\mathbf{0}}, \mathring{\mathbf{1}}, \mathring{\mathbf{p}}, \mathring{\mathbf{s}}\}$ denote the four *ontological* mode labels of the Fourfold Dialectic Algebra (Chapter 1; Definition 1.16 and Lemma 1.20). Fix the ordered index set $\mathcal{I} := \{0, 1, p, s\}$ consistent with the symmetry–corner congruence (Chapter 1; Definition 1.23).

For each locus x, let $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ be the *emergent* modal fiber. Let

$$\mathcal{R}_x : \mathfrak{M} \longrightarrow \mathbb{P}\Big(\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}\Big)$$

be a realization map sending each ontological label to a *ray* in the fiber.

After the inner product on $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ is defined via the Fourfold correlator (Chapter 4; eq. (4.6)), we will choose unit representatives $\mathcal{B}_x := \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\} \subset \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ of the rays $\mathcal{R}_x(\mathring{\alpha}) = [\,|\alpha\rangle_x\,]$ for $\alpha \in \mathcal{I}$. The orthonormality of this frame is established *a posteriori* in Proposition 4.10 below (rather than postulated).

Let $\hat{\mathcal{F}}_\alpha(\cdot)$ be the Fourfold selection operators labelled by $\mathring{\alpha} \in \mathfrak{M}$ (Chapter 1; Definition 1.16), and let $\mathcal{U}(x \leftarrow x'; \gamma)$ be the gauge-covariant transporter generated by the connection $\mathcal{A}$ along a path $\gamma \subset \mathcal{X}_q$ (Chapter 4; eqs. (4.11) and (4.16)). Define the tensor components and block assembly

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') := \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x'), \qquad \hat{\mathbf{G}}_\Lambda(x, x') = \Big[\hat{G}_\Lambda^{\alpha\beta}(x, x')\Big]_{\alpha,\beta\in\mathcal{I}}.$$

For $|\psi_1\rangle_x = \sum_{\alpha\in\mathcal{I}} c_{1\alpha}|\alpha\rangle_x$, $|\psi_2\rangle_{x'} = \sum_{\beta\in\mathcal{I}} c_{2\beta}|\beta\rangle_{x'}$, and $c^{(1)} := (c_{10}, c_{11}, c_{1p}, c_{1s})^\top$, $c^{(2)} := (c_{20}, c_{21}, c_{2p}, c_{2s})^\top$, set the correlator

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] := \sum_{\alpha,\beta\in\mathcal{I}} \overline{c_{1\alpha}}\, \hat{G}_\Lambda^{\alpha\beta}(x, x')\, c_{2\beta} = \Big(c^{(1)}\Big)^\dagger\, \hat{\mathbf{G}}_\Lambda(x, x')\, c^{(2)}.$$

Born valuations of these effects are taken against the universal state (Chapter 1; Definition 1.18); interferometric realisations appear in Chapter 3 (Section 3.8.3 and Corollary 3.21).

Proposition 4.10 (Emergent orthonormality of the Fourfold frame)**.** *Assume the coincident-limit regularity of the Fourfold correlator (Chapter 4; Assumption 4.21) and the well-definedness/positivity of the induced inner product (Chapter 4; Proposition 4.28):*

$$\langle \psi_1 | \psi_2 \rangle_x := \lim_{x' \to x} \left\langle \overset{\circ}{\mathbf{\Psi}} \middle| \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \middle| \overset{\circ}{\mathbf{\Psi}} \right\rangle \quad \textit{(cf. eq. (4.6)).}$$

Then for each x there exists a choice of realization $\mathcal{R}_x$ and unit representatives $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ such that

$$\langle \alpha | \beta \rangle_x = \delta_{\alpha\beta} \qquad (\alpha, \beta \in \{0, 1, p, s\}).$$

Moreover, any two such realizing orthonormal frames at x differ by a unique unitary $U(x) \in \mathrm{U}(4)$.

Proof. Step 1: Gram matrix from the coincident limit. Fix any local realizing frame $\{|e_\alpha\rangle_x\}_{\alpha \in \mathcal{I}}$ of rays $\mathcal{R}_x$. Define the 4×4 Gram matrix $M(x) = [M_{\alpha\beta}(x)]$ by

$$M_{\alpha\beta}(x) := \langle e_\alpha | e_\beta \rangle_x = \lim_{x' \to x} \left\langle \overset{\circ}{\mathbf{\Psi}} \middle| \hat{G}^{\alpha\beta}_\Lambda(x, x') \middle| \overset{\circ}{\mathbf{\Psi}} \right\rangle,$$

which is well-defined by Assumption 4.21 and Proposition 4.28. By sesquilinearity and the Hermitian symmetry of components (Fourfold version of Proposition 4.3), $M(x)$ is Hermitian. Positivity of the inner product implies $M(x)$ is positive-definite.

Step 2: Orthonormal realization via spectral/Cholesky factorization. Since $M(x) > 0$, there exists a unique positive square root $M(x)^{1/2}$ and an invertible $S(x) := M(x)^{-1/2}$. Define new representatives

$$|\alpha\rangle_x \;:=\; \sum_{\beta \in \mathcal{I}} S_{\beta\alpha}(x)\, |e_\beta\rangle_x.$$

Then their Gram matrix is $\langle \alpha | \beta \rangle_x = \mathbf{e}_\alpha^\dagger\, S(x)^\dagger M(x) S(x)\, \mathbf{e}_\beta = \mathbf{e}_\alpha^\dagger\, \mathbb{I}\, \mathbf{e}_\beta = \delta_{\alpha\beta}$, i.e. $\mathcal{B}_x$ is orthonormal.

Step 3: Compatibility with gauge covariance. Under a local frame change $g(x) \in \mathrm{U}(4)$ at the modal fibre (Chapter 4; eq. (4.16)), $\hat{\mathbf{G}}_\Lambda(x, x) \mapsto g(x) \hat{\mathbf{G}}_\Lambda(x, x) g(x)^\dagger$. Hence $M(x) \mapsto g(x) M(x) g(x)^\dagger$, and $S(x) = M(x)^{-1/2} \mapsto S'(x) = g(x) S(x) g(x)^\dagger$. Therefore the orthonormalizing construction is natural with respect to gauge changes.

Step 4: Uniqueness up to unitary. Let $\{|f_\alpha\rangle_x\}$ be another orthonormal realizing frame of the same rays. Since both frames are orthonormal, the change-of-basis matrix $U(x)$ defined by $|f_\alpha\rangle_x = \sum_\beta U_{\beta\alpha}(x) |\beta\rangle_x$ is unitary. Uniqueness of $U(x)$ follows from linear independence of the frame.

Thus there exists a (realizing) orthonormal Fourfold frame at x, unique up to a unitary in $\mathrm{U}(4)$. □

Remark 4.11 (Operational meaning)**.** The entries $M_{\alpha\beta}(x)$ are coincident-limit Born evaluations of the Fourfold components, i.e. $M_{\alpha\beta}(x) = \lim_{x' \to x} \langle \overset{\circ}{\mathbf{\Psi}} |\, \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')\, | \overset{\circ}{\mathbf{\Psi}} \rangle$ (cf. Chapter 3 readouts Section 3.8.3 and Corollary 3.21). The proposition shows that the emergent inner product inherited from these correlators canonically produces an orthonormal modal frame, eliminating the need to postulate orthonormality.

Proposition 4.12 (Sesquilinearity of the Fourfold kernel)**.** *Let* $G := \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ *be the Fourfold Inter-Modal Correlator from Definition 4.9. Then for all* $\lambda, \mu \in \mathbb{C}$*,*

$$G[(\lambda\psi_1 + \mu\phi_1)^*, \psi_2] = \overline{\lambda}\, G[\psi_1^*, \psi_2] + \overline{\mu}\, G[\phi_1^*, \psi_2],$$
$$G[\psi_1^*, \lambda\psi_2 + \mu\phi_2] = \lambda\, G[\psi_1^*, \psi_2] + \mu\, G[\psi_1^*, \phi_2].$$

Proof. Expand in the Fourfold basis $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ (Ch. 1–2; Fourfold/Twofold realisations Definitions 1.16 and 1.23 and Ch. 2 local bases): $|\psi_1\rangle_x = \sum_\alpha c_\alpha^{(1)} |\alpha\rangle_x$, $|\psi_2\rangle_{x'} = \sum_\beta c_\beta^{(2)} |\beta\rangle_{x'}$. By Definition 4.9,

$$G[\psi_1^*, \psi_2] = \sum_{\alpha,\beta} \overline{c_\alpha^{(1)}}\, \hat{G}_\Lambda^{\alpha\beta}(x, x')\, c_\beta^{(2)} = (c^{(1)})^\dagger\, \hat{\mathbf{G}}_\Lambda(x, x')\, c^{(2)}.$$

Linearity of the coefficient maps and matrix multiplication gives conjugate-linearity in the first argument and linearity in the second, identically to the Twofold case (Proposition 4.2) but with $\alpha, \beta \in \{0, 1, p, s\}$. □

Proposition 4.13 (Hermitian symmetry of the Fourfold kernel)**.** *For all* $\alpha, \beta \in \{0, 1, p, s\}$*,*

$$\left(\hat{G}_\Lambda^{\alpha\beta}(x, x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x),$$

and hence for arbitrary ψ_1, ψ_2*,*

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]^\dagger = \hat{G}_\Lambda(\mathfrak{B}_{x'}, \mathfrak{B}_x)[\psi_2^*, \psi_1].$$

Proof. By definition, $\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$, with $\hat{\mathcal{F}}_\alpha$ the Fourfold selectors (Ch. 1; Definition 1.16) and $\mathcal{U}$ the transporter (Ch. 4; eq. (4.11)). Taking adjoints and using $(ABC)^\dagger = C^\dagger B^\dagger A^\dagger$ and $\mathcal{U}(x \leftarrow x'; \gamma)^\dagger = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$ (eq. (4.14)) gives the component identity. Expanding $G[\psi_1^*, \psi_2]$ in coefficients as above and taking adjoints yields the kernel-level identity, exactly as in the Twofold proof (Proposition 4.3). □

Proposition 4.14 (Gauge covariance of the Fourfold kernel)**.** *Under local frame changes* $g : \mathcal{X}_q \to \mathrm{U}(\cdot)$ *(Ch. 4; eq. (4.16)),*

$$\hat{\mathcal{F}}_\alpha(x) \mapsto g(x) \hat{\mathcal{F}}_\alpha(x), \qquad \mathcal{U}(x \leftarrow x'; \gamma) \mapsto g(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, g(x')^\dagger,$$

and the Fourfold block transforms by

$$\hat{\mathbf{G}}_\Lambda(x, x') \mapsto g(x)\, \hat{\mathbf{G}}_\Lambda(x, x')\, g(x')^\dagger.$$

Consequently, any Born expectation in a gauge–covariant state (Ch. 1; Definition 1.18) is gauge–invariant.

Proof. Insert the transformations into $\hat{G}_\Lambda^{\alpha\beta} = \hat{\mathcal{F}}_\alpha^\dagger \mathcal{U} \hat{\mathcal{F}}_\beta$; the $g(x)$ and $g(x')^\dagger$ factors cancel pairwise at the component level, while the assembled block is conjugated at the two endpoints, as a morphism $\mathrm{Hom}(\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})}, \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)})$ (see also the fibre-bundle proof for Twofold, Proposition 4.4). For a co-transforming state $\rho \mapsto g(x) \rho g(x)^\dagger$, cyclicity of trace gives $\mathrm{Tr}(\rho\, \hat{\mathbf{G}}_\Lambda) = \mathrm{Tr}(\rho'\, \hat{\mathbf{G}}'_\Lambda)$. □

Proposition 4.15 (Boundedness of the Fourfold kernel)**.** *If each $\hat{\mathcal{F}}_\alpha(x)$ is bounded and $\|\mathcal{U}(x \leftarrow x';\gamma)\| = 1$, then for any ψ_1, ψ_2,*

$$\left\|\hat{G}_\Lambda[\psi_1^*, \psi_2]\right\| \le \|c^{(1)}\|\,\|c^{(2)}\| \max_{\alpha,\beta\in\{0,1,p,s\}} \left\|\hat{\mathcal{F}}_\alpha(x)\right\| \left\|\hat{\mathcal{F}}_\beta(x')\right\|.$$

Proof. Write $G[\psi_1^*, \psi_2] = \sum_{\alpha,\beta} \overline{c_\alpha^{(1)}}\, \hat{G}_\Lambda^{\alpha\beta}\, c_\beta^{(2)}$. By submultiplicativity and $\|\mathcal{U}\| = 1$, $\|\hat{G}_\Lambda^{\alpha\beta}\| \le \|\hat{\mathcal{F}}_\alpha(x)\|\,\|\hat{\mathcal{F}}_\beta(x')\| \le K$, with $K := \max_{\alpha,\beta} \|\hat{\mathcal{F}}_\alpha(x)\|\,\|\hat{\mathcal{F}}_\beta(x')\|$. Hence

$$\|G[\psi_1^*, \psi_2]\| \le K \sum_{\alpha,\beta} |c_\alpha^{(1)}|\,|c_\beta^{(2)}| = K\,\|c^{(1)}\|_1\,\|c^{(2)}\|_1.$$

If the coefficient norm on $\mathbb{C}^4$ is $\|\cdot\|_1$, we are done. If the Euclidean norm is used, $\|v\|_1 \le \sqrt{4}\,\|v\|_2$, so $\|G[\psi_1^*, \psi_2]\| \le 4K\,\|c^{(1)}\|\,\|c^{(2)}\|$. The display in the proposition holds verbatim under the ℓ^1 convention and up to a universal factor 4 under the ℓ^2 convention (cf. the Twofold discussion, Proposition 4.5). □

Proposition 4.16 (Compatibility with the Fourfold Dialectic Algebra)**.** *Let $L, R \in \mathrm{End}(\mathbb{C}^{\{0,1,p,s\}})$ encode the left/right actions of the Fourfold Dialectic Algebra on mode indices (Ch. 1; Definition 1.16 and Lemma 1.20). Then the transformed correlator block is*

$$(L \cdot \hat{\mathbf{G}}_\Lambda \cdot R^\dagger)^{\alpha\beta} = \sum_{\gamma,\delta} L^\alpha{}_\gamma\, \hat{G}_\Lambda^{\gamma\delta}\, (R^\dagger)_\delta{}^\beta.$$

In particular, the Twofold block $\hat{\mathbf{G}}_{(0,1)}(x, x')$ is the top-left 2×2 submatrix, and the off-diagonal blocks couple $\{0,1\}$ with $\{p,s\}$.

Proof. Algebra actions on mode indices correspond (via the bridge congruence, Ch. 1; Lemma 1.20) to linear recombinations of selectors:

$$\hat{\mathcal{F}}_\alpha \;\longmapsto\; \hat{\mathcal{F}}'_\alpha := \sum_\gamma L^\alpha{}_\gamma\, \hat{\mathcal{F}}_\gamma, \qquad \hat{\mathcal{F}}_\beta \;\longmapsto\; \hat{\mathcal{F}}'_\beta := \sum_\delta R^\beta{}_\delta\, \hat{\mathcal{F}}_\delta.$$

Thus

$$\hat{G}'^{\alpha\beta}_\Lambda = (\hat{\mathcal{F}}'_\alpha)^\dagger\, \mathcal{U}\, \hat{\mathcal{F}}'_\beta = \sum_{\gamma,\delta} \overline{L^\alpha{}_\gamma}\, \hat{\mathcal{F}}_\gamma^\dagger\, \mathcal{U}\, R^\beta{}_\delta\, \hat{\mathcal{F}}_\delta = \sum_{\gamma,\delta} L^\alpha{}_\gamma\, \hat{G}_\Lambda^{\gamma\delta}\, (R^\dagger)_\delta{}^\beta,$$

which is the claimed block relation. Selecting indices $\alpha, \beta \in \{0,1\}$ extracts the top-left submatrix $\hat{\mathbf{G}}_{(0,1)}$ (cf. the definition of the Twofold correlator, Definition 4.1); entries with one index in $\{0,1\}$ and the other in $\{p,s\}$ are the off-diagonal couplings. □

GNS anchoring and notational convention. By Definition 1.34, the Quantum Holo-State induces a GNS triple $(\pi_{\overset{\circ}{\Psi}},\ \mathcal{H}_{\overset{\circ}{\Psi}},\ |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle)$, and we identify $\mathcal{H}_{\mathrm{em}} := \mathcal{H}_{\overset{\circ}{\Psi}}$. For any $A \in \mathcal{A}$,

$$\omega^{\overset{\circ}{\Psi}}(A) = \left\langle \Omega_{\omega^{\overset{\circ}{\Psi}}} \right| \pi_{\overset{\circ}{\Psi}}(A) \left| \Omega_{\omega^{\overset{\circ}{\Psi}}} \right\rangle.$$

Convention. Hatted symbols (e.g. $\hat{\mathcal{F}}_\alpha,\ \hat{G}_\Lambda^{\alpha\beta}$) denote represented operators $\hat{A} := \pi_{\overset{\circ}{\Psi}}(A) \in \mathcal{B}(\mathcal{H}_{\mathrm{em}})$. Accordingly, $\langle \overset{\circ}{\boldsymbol{\Psi}}| \cdot |\overset{\circ}{\boldsymbol{\Psi}}\rangle$ abbreviates $\langle \Omega_{\omega^{\overset{\circ}{\Psi}}}| \cdot |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle$ and equals $\omega^{\overset{\circ}{\Psi}}(\cdot)$ on $\mathcal{A}$.

Proposition 4.17 (GNS anchoring: representation-theoretic properties)**.** *Let* $(\pi_{\overset{\circ}{\Psi}}, \mathcal{H}_{\mathrm{em}}, |\Omega\rangle)$ *be the GNS triple of* $\omega^{\overset{\circ}{\Psi}}$ *from Definition 1.34. Then:*

1. **$*$-representation.**
   The map $\pi_{\overset{\circ}{\Psi}} : \mathcal{A} \to \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ *is a $*$-homomorphism:*

$$\widehat{A+B} = \hat{A} + \hat{B}, \quad \widehat{\lambda A} = \lambda \hat{A}, \quad \widehat{AB} = \hat{A}\,\hat{B}, \quad \widehat{A^*} = \hat{A}^\dagger.$$

2. **Cyclicity.**
   $|\Omega\rangle$ *is cyclic:* $\overline{\pi_{\overset{\circ}{\Psi}}(\mathcal{A})\,|\Omega\rangle} = \mathcal{H}_{\mathrm{em}}$.

3. **State recovery.**
   For all $A \in \mathcal{A}$,

$$\begin{aligned} \omega^{\overset{\circ}{\Psi}}(A) &= \langle \Omega \mid \hat{A} \mid \Omega \rangle \\ &= \langle \overset{\circ}{\Psi} \mid \hat{A} \mid \overset{\circ}{\Psi} \rangle. \end{aligned} \tag{4.5}$$

   In particular, for any noncommutative polynomial p *in elements of* $\mathcal{A}$*, we have*

$$\omega^{\overset{\circ}{\Psi}}\Big(p(A_1, \ldots, A_n)\Big) = \langle \Omega |\, \widehat{p(A_1, \ldots, A_n)}\, |\Omega\rangle.$$

4. **Norm control.**
   If $\mathcal{A}$ *is a C*-algebra, then* $\|\hat{A}\| \le \|A\|_{\mathcal{A}}$ *(GNS is contractive).*

5. **Uniqueness up to unitary.**
   If $(\pi', \mathcal{H}', |\Omega'\rangle)$ *is another GNS triple for the same state, there exists a unique unitary* $U : \mathcal{H}_{\mathrm{em}} \to \mathcal{H}'$ *with* $U\,|\Omega\rangle = |\Omega'\rangle$ *and* $U\,\hat{A}\,U^\dagger = \pi'(A)$ *for all* $A \in \mathcal{A}$.

Proof. The construction underlying Definition 1.34 proceeds by the standard GNS steps: define the left ideal $N_\omega := \{A \in \mathcal{A} : \ \omega^{\overset{\circ}{\Psi}}(A^*A) = 0\}$, form the pre-Hilbert space $\mathcal{A}/N_\omega$ with inner product $\langle [A], [B] \rangle := \omega^{\overset{\circ}{\Psi}}(A^*B)$, and complete to obtain $\mathcal{H}_{\mathrm{em}}$. Set $\pi_{\overset{\circ}{\Psi}}(C)[A] := [CA]$ and let $|\Omega\rangle := [\mathbb{1}]$ (if $\mathcal{A}$ is unital; otherwise use a unitisation). Then (1) follows since π respects linearity, products and adjoints on cosets; (2) holds because $\mathrm{span}\{[A] : A \in \mathcal{A}\}$ is dense by construction; (3) is immediate: $\langle \Omega | \hat{A} | \Omega \rangle = \langle [\mathbb{1}], [A] \rangle = \omega^{\overset{\circ}{\Psi}}(A)$. For (4), if $\mathcal{A}$ is a C*-algebra, then for any $[B]$,

$$\|\hat{A}[B]\|^2 = \langle [B], \widehat{A^*A}[B] \rangle = \omega^{\overset{\circ}{\Psi}}(B^*A^*AB) \le \|A\|_{\mathcal{A}}^2\, \omega^{\overset{\circ}{\Psi}}(B^*B) = \|A\|_{\mathcal{A}}^2\, \|[B]\|^2,$$

so $\|\hat{A}\| \le \|A\|_{\mathcal{A}}$. Item (5) is the standard GNS uniqueness: the linear map $U : \pi(\mathcal{A})|\Omega\rangle \to \pi'(\mathcal{A})|\Omega'\rangle$ defined by $U\,\pi(A)|\Omega\rangle := \pi'(A)|\Omega'\rangle$ is well-defined, isometric, extends by density to a unitary intertwiner, and satisfies the stated relations. □

Corollary 4.18 (Notation consistency for Fourfold objects)**.** *Let* $\hat{\mathcal{F}}_\alpha := \pi_{\overset{\circ}{\Psi}}(\mathcal{F}_\alpha)$ *be the represented Fourfold selection operators (Chapter 1; Definition 1.16) and* $\hat{G}_\Lambda^{\alpha\beta}(x, x') :=$

$\hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x\leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x')$ *the represented components of the Fourfold correlator (Chapter 4). Then:*

$$\widehat{\mathcal{F}_\alpha^*} = \hat{\mathcal{F}}_\alpha^\dagger, \qquad \widehat{\mathcal{F}_\alpha\,\mathcal{F}_\beta} = \hat{\mathcal{F}}_\alpha\,\hat{\mathcal{F}}_\beta,$$

and for any polynomial p in the $\mathcal{F}_\alpha$, $\langle \overset{\circ}{\boldsymbol{\Psi}}|\, p(\widehat{\{\mathcal{F}_\alpha\}})\,|\overset{\circ}{\boldsymbol{\Psi}}\rangle = \omega^{\overset{\circ}{\boldsymbol{\Psi}}}\big(p(\{\mathcal{F}_\alpha\})\big)$.

Remark 4.19 (On external unitaries and transport)**.** If $\mathcal{U}(x\leftarrow x';\gamma)\in\mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is generated by the emergent connection $\mathcal{A}$ (Chapter 4; eq. (4.11)), it need not lie in $\pi(\mathcal{A})$. All identities above still apply to mixed expressions $\hat{\mathcal{F}}_\alpha^\dagger\,\mathcal{U}\,\hat{\mathcal{F}}_\beta$, since π handles the algebraic parts while $\mathcal{U}$ acts unitarily on $\mathcal{H}_{\mathrm{em}}$. Gauge covariance and Born expectations for such expressions are treated in Proposition 4.14 and Chapter 1 (Definition 1.18).

Definition 4.20 (Emergent inner product and fibre Hilbert space)**.** Let $\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})$ be the Fourfold Inter-Modal Correlator from Definition 4.9 and let $\omega^{\overset{\circ}{\boldsymbol{\Psi}}}$ be the state associated to the Quantum Holo-State via the GNS anchoring of Proposition 4.17. For ψ_1,ψ_2 in the (a priori) modal fibre at x, define the *emergent (pre-)inner product* by the coincident-limit formula

$$\langle\psi_1|\psi_2\rangle_x := \lim_{x'\to x}\Big\langle \overset{\circ}{\boldsymbol{\Psi}}\Big|\,\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]\,\Big|\overset{\circ}{\boldsymbol{\Psi}}\Big\rangle = \lim_{x'\to x}\omega^{\overset{\circ}{\boldsymbol{\Psi}}}(G_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2])\,. \tag{4.6}$$

Whenever the limit exists and is independent of the approach to $x'\to x$, the pairing $\langle\cdot|\cdot\rangle_x$ is well defined and, by Propositions 4.12 and 4.13, is sesquilinear and conjugate symmetric. If, in addition, $\langle\psi|\psi\rangle_x\geq 0$ for all ψ (positivity of the coincident limit), set the null space

$$\mathcal{N}_x := \{\psi:\ \langle\psi|\psi\rangle_x = 0\},$$

and equip the quotient $\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x) := \mathrm{Dom}/\mathcal{N}_x$ with the induced inner product $\langle[\psi_1],[\psi_2]\rangle_x := \langle\psi_1|\psi_2\rangle_x$. Its completion is the *emergent modal fibre Hilbert space*

$$\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}} \;:=\; \overline{\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x)}^{\,\|\cdot\|_x}.$$

By Proposition 4.14, the scalar $\langle\psi_1|\psi_2\rangle_x$ is gauge invariant (Born evaluation in a gauge–covariant state), and by Proposition 4.10 there exists a realizing orthonormal Fourfold frame $\{|0\rangle_x,|1\rangle_x,|p\rangle_x,|s\rangle_x\}$ for this inner product.

Assumption 4.21 (Regularity for the coincident limit)**.** *For each $\alpha,\beta\in\{0,1,p,s\}$, the map $(x,x')\mapsto\hat{G}^{\alpha\beta}_\Lambda(x,x')$ is weakly continuous on a neighborhood of the diagonal in $\mathcal{X}_q\times\mathcal{X}_q$, and the limit $\lim_{x'\to x}\hat{G}^{\alpha\beta}_\Lambda(x,x')$ exists in the weak operator topology on $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$.*

Lemma 4.22 (Strong limits of uniformly bounded products)**.** *Let $A_n,B_n\in\mathcal{B}(\mathcal{H})$ with $A_n\to A$ and $B_n\to B$ in the strong operator topology (SOT), and $\sup_n\|A_n\|<\infty$, $\sup_n\|B_n\|<\infty$. Then $A_nB_n\to AB$ in SOT.*

Proof. Recall that SOT convergence means: for every $v\in\mathcal{H}$, $A_nv\to Av$ and $B_nv\to Bv$ in the norm of $\mathcal{H}$. Fix $v\in\mathcal{H}$. We estimate

$$\|A_nB_nv-ABv\| = \|A_n(B_nv-Bv)+(A_n-A)Bv\| \leq \|A_n\|\,\|B_nv-Bv\| + \|(A_n-A)Bv\|.$$

By assumption, $M_A := \sup_n \|A_n\| < \infty$ and $B_n v \to Bv$, so the first term is bounded by $M_A \|B_n v - Bv\| \to 0$. For the second term, Bv is a fixed vector and $A_n \to A$ strongly, hence $\|(A_n - A)Bv\| \to 0$. Given $\varepsilon > 0$, choose N_1 with $\|B_n v - Bv\| < \varepsilon/(2M_A)$ for $n \geq N_1$, and N_2 with $\|(A_n - A)Bv\| < \varepsilon/2$ for $n \geq N_2$. Then for $n \geq N := \max\{N_1, N_2\}$ we have $\|A_n B_n v - ABv\| < \varepsilon$. Since v was arbitrary, $A_n B_n \to AB$ in SOT. □

Remark 4.23 (Variants and minimal hypotheses)**.** (1) The proof only used the uniform bound on $\{A_n\}$. By the alternative decomposition

$$A_n B_n - AB = (A_n - A)B_n + A(B_n - B),$$

one obtains the same conclusion assuming instead $\sup_n \|B_n\| < \infty$. Hence it suffices to have SOT convergence of both sequences and a uniform bound on *one* of them.

(2) In fact, if $A_n \to A$ (resp. $B_n \to B$) in SOT, then $\{A_n\}$ (resp. $\{B_n\}$) is automatically uniformly bounded by the Uniform Boundedness Principle, since for each v, $\sup_n \|A_n v\| < \infty$. Thus one can state Lemma 4.22 with the uniform boundedness conditions omitted; they follow from SOT convergence.

(3) The argument extends verbatim to nets $\{A_\iota\}$, $\{B_\iota\}$ indexed by a directed set, yielding $A_\iota B_\iota \to AB$ in SOT.

Meaning and implications of Proposition 4.25. The proposition formalises the idea that, under mild continuity and boundedness hypotheses on the Fourfold selectors and the parallel transport (H1–H2), each correlator component $\hat{G}_\Lambda^{\alpha\beta}(y, y')$ behaves *regularly* as the two loci y', y approach each other along the base $\mathcal{X}_q$ (for background on gauge transport on fibre bundles see [248, 225, 84]):

(i) *Weak continuity in both endpoints.* The map $(y, y') \mapsto \hat{G}_\Lambda^{\alpha\beta}(y, y')$ is continuous in the weak operator topology (WOT). Operationally, Born expectations and matrix elements $\langle u, \hat{G}_\Lambda^{\alpha\beta}(y, y')v\rangle$ vary continuously with the endpoints (y, y') (see standard references on operator topologies, e.g. [367, 368, 369]).

(ii) *Well-defined coincident limit in strong sense.* As $y' \to y$ along any family of shrinking paths $\gamma_{y \leftarrow y'}$, the transporter tends to the identity, so the correlator converges in the strong operator topology (SOT) to the *local* product of selectors:

$$\lim_{y' \to y} \hat{G}_\Lambda^{\alpha\beta}(y, y') \;=\; \hat{\mathcal{F}}_\alpha^\dagger(y)\, \hat{\mathcal{F}}_\beta(y).$$

This strong limit is robust enough to justify the coincident-limit constructions used to define the emergent inner product (Definition 4.20) and, subsequently, the orthonormal Fourfold frame (Proposition 4.10); compare general SOT product limits and uniform boundedness criteria in [367, 369].

Intuitively: (H1) prevents the selector fields from "jumping" or blowing up, and (H2) ensures that transport over vanishing paths becomes the identity in a controlled way. Together, these imply that near the diagonal $y' = y$, the nonlocal two-point correlator reduces continuously to a local object, exactly the product $\hat{\mathcal{F}}_\alpha^\dagger(y)\hat{\mathcal{F}}_\beta(y)$.

Remark 4.24 (Topologies on operators: SOT vs. WOT continuity)**.** Let $\mathcal{H}$ be a Hilbert space and $\mathcal{B}(\mathcal{H})$ the bounded operators on $\mathcal{H}$.

- A net (or sequence) $T_\nu \in \mathcal{B}(\mathcal{H})$ *converges strongly* to T (SOT convergence), written $T_\nu \xrightarrow{\text{SOT}} T$, if $T_\nu v \to Tv$ in norm for every $v \in \mathcal{H}$. A map $x \mapsto T(x)$ is *SOT–continuous* at x_0 if $T(x)v \to T(x_0)v$ for all v whenever $x \to x_0$ [367, 369].
- T_ν *converges weakly* to T (WOT convergence), written $T_\nu \xrightarrow{\text{WOT}} T$, if $\langle u, T_\nu v\rangle \to \langle u, Tv\rangle$ for all $u, v \in \mathcal{H}$. A map is *WOT–continuous* at x_0 if these scalar matrix elements vary continuously [367, 368].

SOT convergence $\Rightarrow$ WOT convergence, but not conversely in general. In Proposition 4.25, the stronger SOT limit in (ii) implies the weaker WOT limit automatically; in (i) only WOT continuity is claimed because products of SOT–continuous factors need not be SOT–continuous without uniform bounds. Here, unitarity of $\mathcal{U}$ and uniform boundedness of $\hat{\mathcal{F}}_\alpha$ supply those bounds and yield SOT limits at coincidence (see also the product-limit criteria in [367, 369]).

Proposition 4.25 (Regularity of the coincident limit from continuity hypotheses)**.** *Fix $\alpha, \beta \in \{0, 1, p, s\}$. Suppose the following hold on a neighbourhood $\mathcal{U} \subset \mathcal{X}_q$ of x:*

(H1) *Selector continuity and uniform bounds. The field $x \mapsto \hat{\mathcal{F}}_\alpha(x) \in \mathcal{B}(\mathcal{H}_{\text{em}})$ is SOT–continuous on $\mathcal{U}$ (and thus WOT–continuous), and $\sup_{y\in\mathcal{U}} \|\hat{\mathcal{F}}_\alpha(y)\| < \infty$ for each α. (Chapter 1 selectors; Definition 1.16.)*

(H2) *Transport continuity and unitarity. For a continuous choice of paths $\gamma_{y\leftarrow y'}$ with $\text{len}(\gamma_{y\leftarrow y'}) \to 0$ as $y' \to y$, the transporter $\mathcal{U}(y \leftarrow y'; \gamma_{y\leftarrow y'})$ is jointly SOT–continuous on $\mathcal{U} \times \mathcal{U}$, unitary, and satisfies $\mathcal{U}(y \leftarrow y; \text{id}) = \mathbb{I}$ (Chapter 4 transport; eqs. (4.11) and (4.14)).*

Then:

(i) The map $(y, y') \mapsto \hat{G}^{\alpha\beta}_\Lambda(y, y') := \hat{\mathcal{F}}^\dagger_\alpha(y)\, \mathcal{U}(y \leftarrow y'; \gamma_{y\leftarrow y'})\, \hat{\mathcal{F}}_\beta(y')$ is WOT–continuous on $\mathcal{U} \times \mathcal{U}$.

(ii) The coincident limit exists in SOT (hence WOT) and equals

$$\lim_{y'\to y} \hat{G}^{\alpha\beta}_\Lambda(y, y') = \hat{\mathcal{F}}^\dagger_\alpha(y)\, \hat{\mathcal{F}}_\beta(y).$$

Proof. Fix sequences $y_n \to y$ and $y'_n \to y$ in $\mathcal{U}$. Set

$$A_n := \hat{\mathcal{F}}^\dagger_\alpha(y_n), \quad B_n := \mathcal{U}(y_n \leftarrow y'_n; \gamma_{y_n\leftarrow y'_n}), \quad C_n := \hat{\mathcal{F}}_\beta(y'_n),$$

and $A := \hat{\mathcal{F}}^\dagger_\alpha(y)$, $B := \mathbb{I}$, $C := \hat{\mathcal{F}}_\beta(y)$. By (H1), $A_n \to A$ and $C_n \to C$ in SOT and are uniformly bounded near y. By (H2), $B_n \to B$ in SOT and $\|B_n\| = 1$. Applying Lemma 4.22 twice, first to $D_n := B_n C_n$ (with limit $BC = C$), and then to $A_n D_n$, yields

$$A_n B_n C_n \xrightarrow[\text{SOT}]{} ABC = \hat{\mathcal{F}}^\dagger_\alpha(y)\, \hat{\mathcal{F}}_\beta(y).$$

This proves (ii). In particular, SOT–convergence implies WOT–convergence, so the limit exists in WOT.

For (i), fix $v, w \in \mathcal{H}_{\mathrm{em}}$ and write

$$\langle v, \hat{G}_{\Lambda}^{\alpha\beta}(y_n, y_n')w\rangle = \langle A_n^{\dagger} v,\, B_n C_n w\rangle.$$

By (H1)–(H2), $A_n^{\dagger} v \to A^{\dagger} v$ and $B_n C_n w \to BCw$ in norm; hence the scalar products converge. This is precisely WOT–continuity at (y, y). Since the argument is local and (y, y) was arbitrary, we have WOT–continuity on $\mathcal{U} \times \mathcal{U}$. □

Corollary 4.26 (Verification of Assumption 4.21)**.** *Under Proposition 4.25 (H1)–(H2), the regularity statement of Assumption 4.21 holds. Moreover,*

$$\lim_{x' \to x} \hat{G}_{\Lambda}^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_{\alpha}^{\dagger}(x)\, \hat{\mathcal{F}}_{\beta}(x) \quad \textit{in SOT and WOT.}$$

Remark 4.27 (Sources of (H1)–(H2) from Chapters 1–4)**.**

- The selector fields $\hat{\mathcal{F}}_{\alpha}(x)$ arise from the Fourfold Dialectic Algebra via the bridge congruence (Ch. 1; Definition 1.16 and Lemma 1.20); their boundedness is assumed in Proposition 4.15. Smooth dependence on x (hence SOT–continuity) follows if the realization map $x \mapsto \mathcal{R}_x$ is smooth in the local trivialisation of the modal bundle.
- The transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ is the path-ordered exponential of the connection $\mathcal{A}$ (Ch. 4; eq. (4.11)). If $\mathcal{A}$ is (locally) bounded and continuous, standard ODE results on Banach spaces give joint SOT–continuity in the endpoints and $\mathcal{U}(x \leftarrow x) = \mathbb{I}$.
- The gauge-covariant behaviour of the limit is consistent with Proposition 4.14: under $g(x)$, both sides transform by $T \mapsto g(x)\, T\, g(x)^{\dagger}$.

Proposition 4.28 (Well-defined fiber inner product)**.** *Under Assumption 4.21, the sesquilinear form*

$$\langle \psi_1 | \psi_2 \rangle_x := \lim_{x' \to x} \left\langle \mathring{\mathbf{\Psi}} \right| \hat{G}_{\Lambda}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \left| \mathring{\mathbf{\Psi}} \right\rangle$$

is positive semidefinite. Moreover, the Cauchy–Schwarz inequality holds, and the quotient by the null space followed by completion yields a Hilbert space canonically isomorphic to $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$.

Proof. Step 1: Well-definedness and sesquilinearity. Assumption 4.21 asserts that each component $(x, x') \mapsto \hat{G}_{\Lambda}^{\alpha\beta}(x, x')$ is weakly continuous on a neighbourhood of the diagonal and admits a weak-operator limit as $x' \to x$. For fixed ψ_1, ψ_2 and a fixed GNS vector, weak convergence of $\hat{G}_{\Lambda}^{\alpha\beta}(x, x')$ implies convergence of the scalar matrix elements $\langle \mathring{\mathbf{\Psi}} | \hat{G}_{\Lambda}^{\alpha\beta}(x, x') | \mathring{\mathbf{\Psi}} \rangle$. By linearity of the correlator in each slot (Fourfold version of Proposition 4.12) and linearity of the state, the limit preserves conjugate linearity in the first argument and linearity in the second, so $\langle \cdot | \cdot \rangle_x$ is sesquilinear.

Step 2: Conjugate symmetry. Using the Hermitian symmetry of the correlator (Fourfold version of Proposition 4.13) and the continuity/limit in Assumption 4.21, we obtain

$$\langle \psi_1 | \psi_2 \rangle_x = \overline{\langle \psi_2 | \psi_1 \rangle_x},$$

i.e. conjugate symmetry.

Step 3: Positivity of the coincident limit. We now show $\langle\psi|\psi\rangle_x \geq 0$. Under the natural continuity hypotheses for selectors and transport (cf. Proposition 4.25), the coincident limit exists in the *strong* operator topology and satisfies

$$\lim_{x'\to x} \hat{G}_\Lambda^{\alpha\beta}(x,x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\hat{\mathcal{F}}_\beta(x).$$

Hence, writing $|\psi\rangle_x = \sum_\beta c_\beta\,|\beta\rangle_x$ and $F_x(c) := \sum_\beta c_\beta\,\hat{\mathcal{F}}_\beta(x)$, we have

$$\langle\psi|\psi\rangle_x = \lim_{x'\to x} \Big\langle \mathring{\mathbf{\Psi}}\Big|\sum_{\alpha,\beta} \overline{c_\alpha}\,\hat{G}_\Lambda^{\alpha\beta}(x,x')\,c_\beta\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle = \Big\langle \mathring{\mathbf{\Psi}}\Big|\,F_x(c)^\dagger F_x(c)\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle = \Big\|F_x(c)\,|\mathring{\mathbf{\Psi}}\rangle\Big\|^2 \;\geq\; 0.$$

(The last equality uses the GNS anchoring; cf. Proposition 4.17.) Thus the form is positive semidefinite.[1]

Step 4: Cauchy–Schwarz inequality. For $t \in \mathbb{C}$,

$$0 \leq \langle\psi_1 + t\psi_2\,|\,\psi_1 + t\psi_2\rangle_x = \langle\psi_1|\psi_1\rangle_x + t\,\langle\psi_2|\psi_1\rangle_x + \bar{t}\,\langle\psi_1|\psi_2\rangle_x + |t|^2\,\langle\psi_2|\psi_2\rangle_x.$$

Choosing $t = -\frac{\langle\psi_1|\psi_2\rangle_x}{\langle\psi_2|\psi_2\rangle_x}$ (or $t = 0$ if $\psi_2 = 0$) and using conjugate symmetry yields $|\langle\psi_1|\psi_2\rangle_x|^2 \leq \langle\psi_1|\psi_1\rangle_x\,\langle\psi_2|\psi_2\rangle_x$. Hence Cauchy–Schwarz holds.

Step 5: Null space, quotient and completion. Let $\mathcal{N}_x := \{\psi : \langle\psi|\psi\rangle_x = 0\}$ be the null space. By Cauchy–Schwarz, $\langle\psi|\cdot\rangle_x \equiv 0$ for all $\psi \in \mathcal{N}_x$, so the form descends to an inner product on the quotient space $\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x) := \mathrm{Dom}/\mathcal{N}_x$ via $\langle[\psi_1],[\psi_2]\rangle_x := \langle\psi_1|\psi_2\rangle_x$. Its completion

$$\widehat{\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x)}$$

is a Hilbert space by construction.

Step 6: Canonical identification with $\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$. By Definition 4.20, the emergent modal fibre Hilbert space at x is *defined* as the completion of this very quotient with respect to $\langle\cdot|\cdot\rangle_x$, i.e. $\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}} := \overline{\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x)}^{\|\cdot\|_x}$. Therefore the identity map on representatives induces a canonical unitary isomorphism $\widehat{\mathcal{H}^0_{\mathrm{mod}}(\mathfrak{B}_x)} \cong \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$. Moreover, by Proposition 4.10 there exists a realizing orthonormal Fourfold frame $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ in this Hilbert space, unique up to a unitary at x.

Combining Steps 1–6 proves the proposition. □

Remark 4.29 (Gauge invariance of the fibre metric)**.** Let $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ be a local frame change. By Proposition 4.14 the Fourfold components transform as

$$\hat{G}_\Lambda^{\alpha\beta}(x,x') \;\longmapsto\; \hat{G}_\Lambda^{\alpha\beta\prime}(x,x') = g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x,x')\,g(x')^\dagger.$$

There are two equivalent viewpoints:

[1] Even if one only assumes the weak-operator limit of Assumption 4.21, the above identity holds along any subnet for which the product representation is valid (as in Proposition 4.25); the limit of nonnegative numbers remains nonnegative.

(Passive, coordinates co-transform). Writing $|\psi_1\rangle_x = \sum_\alpha c^{(1)}_\alpha |\alpha\rangle_x$ and $|\psi_2\rangle_{x'} = \sum_\beta c^{(2)}_\beta |\beta\rangle_{x'}$, the coefficients transform as $c^{(1)} \mapsto c^{(1)\prime} = g(x)\, c^{(1)}$ and $c^{(2)} \mapsto c^{(2)\prime} = g(x')\, c^{(2)}$. Then, for each (x, x'),

$$\Big(c^{(1)\prime}\Big)^\dagger \hat{\mathbf{G}}'_\Lambda(x, x')\, c^{(2)\prime} = (c^{(1)})^\dagger\, \hat{\mathbf{G}}_\Lambda(x, x')\, c^{(2)}.$$

Taking the Born expectation in the fixed GNS vector (notation of Proposition 4.17) shows the scalar kernel value is invariant pointwise, hence also its coincident limit. Therefore, by Definition 4.20, $\langle\psi_1|\psi_2\rangle_x$ is gauge invariant.

(Active, state co-transforms). Keep the coefficients fixed and transform operators as above together with the GNS state $\rho \mapsto \rho' = g(x)\rho g(x)^\dagger$ at the x-anchor (or the vector $|\Omega\rangle \mapsto |\Omega'\rangle = g(x)|\Omega\rangle$). By cyclicity of the trace and the endpoint conjugations,

$$\mathrm{Tr}\Big(\rho\, \hat{\mathbf{G}}_\Lambda(x, x')\Big) = \mathrm{Tr}\Big(\rho'\, \hat{\mathbf{G}}'_\Lambda(x, x')\Big),$$

so the Born evaluation is invariant for each (x, x'). In the coincident limit $x' \to x$, both endpoint actions identify, and invariance persists.

In both viewpoints, the inner product defined by the coincident-limit prescription of Definition 4.20 is independent of the choice of local gauge. Hence the fibre metric $\langle\cdot|\cdot\rangle_x$ is well defined on the emergent modal bundle and gauge invariant.

Remark 4.30 (Point-splitting and smearing)**.** If the coincident limit requires regularization (e.g., distributional singularities), adopt point-splitting with a smooth bump function χ_ϵ supported near x:

$$\langle\psi_1|\psi_2\rangle_x = \lim_{\epsilon\to 0} \int_{\mathcal{X}_q} \chi_\epsilon(x, x') \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle \, \mathrm{d}\mu(x').$$

This preserves gauge covariance and positivity under mild conditions.

Definition 4.31 (Approximate identity on the base and adapted paths)**.** Let $(\mathcal{X}_q, \mu)$ be the base with a chosen system of normal neighbourhoods. An *approximate identity* at $x \in \mathcal{X}_q$ is a net $\{\chi_\epsilon(x, \cdot)\}_{\epsilon>0} \subset C^\infty_c(\mathcal{X}_q)$ such that:

(AI1) $\chi_\epsilon(x, x') \geq 0$, $\mathrm{supp}_{x'}\, \chi_\epsilon(x, \cdot) \subset B_\epsilon(x)$, and $\int_{\mathcal{X}_q} \chi_\epsilon(x, x')\, \mathrm{d}\mu(x') = 1$.

(AI2) For any continuous f on a neighbourhood of x, $\lim_{\epsilon\to 0} \int \chi_\epsilon(x, x')\, f(x')\, \mathrm{d}\mu(x') = f(x)$.

Fix a continuous choice of paths $\gamma_{x\leftarrow x'}$ with $\mathrm{len}(\gamma_{x\leftarrow x'}) \to 0$ as $x' \to x$ (e.g. the unit-speed geodesic in the normal neighbourhood).

Definition 4.32 (Smeared Fourfold kernel and smeared emergent inner product)**.** For $\psi_1, \psi_2 \in \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$ and an approximate identity $\{\chi_\epsilon\}$ as in Definition 4.31, define the *smeared Fourfold kernel* and *smeared inner product* by

$$\hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x)[\psi_1^*, \psi_2] := \int_{\mathcal{X}_q} \chi_\epsilon(x, x')\, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]\, \mathrm{d}\mu(x'),$$

$$\langle\psi_1|\psi_2\rangle^{(\epsilon)}_x := \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x)[\psi_1^*, \psi_2] \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle.$$

Proposition 4.33 (Gauge covariance and locality of the smeared kernel)**.** *Under the gauge law of Proposition 4.14,*

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'}) \mapsto g(x)\, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})\, g(x')^\dagger,$$

one has

$$\hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x) \;\mapsto\; g(x)\, \hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x)\, g(x)^\dagger, \qquad \langle \psi_1 | \psi_2 \rangle^{(\epsilon)}_x \text{ is gauge invariant.}$$

Moreover, $\hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x)$ depends only on the germ of the kernel near x and the choice of adapted paths $\gamma_{x \leftarrow x'}$.

Proof. Insert the gauge transformation under the integral and use linearity:

$$\begin{aligned} \hat{G}^{(\epsilon)}_\Lambda(\mathfrak{B}_x) &\mapsto \int \chi_\epsilon\, g(x) \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'}) g(x')^\dagger \, \mathrm{d}\mu(x') \\ &= g(x) \Big(\int \chi_\epsilon\, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})\, \mathrm{d}\mu(x') \Big) \underbrace{\Big(\int \chi_\epsilon\, g(x')^\dagger \, \mathrm{d}\mu(x') \Big)}_{= g(x)^\dagger}, \end{aligned}$$

where the last identity follows from (AI2) applied to the continuous map $x' \mapsto g(x')^\dagger$. Taking the Born expectation in the GNS vector (gauge co-transforming at x) yields invariance. Locality follows from $\operatorname{supp} \chi_\epsilon \subset B_\epsilon(x)$. □

Theorem 4.34 (Moore–Aronszajn, vector–valued specialization to the smeared kernel)**.** *Let $\mathcal{X}_q$ be the base and fix $x \in \mathcal{X}_q$. Suppose the matrix–valued kernel*

$$K^{\alpha\beta}(x', x'') := \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \, \hat{G}^{\alpha\beta}_\Lambda(x', x'') \, \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle, \qquad \alpha, \beta \in \{0, 1, p, s\},$$

is Hermitian, locally bounded, and of positive type on a normal neighbourhood of x (cf. (4.8)). For any approximate identity χ_ϵ at x (Definition 4.31), define the smeared kernel

$$K^{(\epsilon)}(x', x'') \;:=\; \sqrt{\chi_\epsilon(x, x')}\, K(x', x'') \sqrt{\chi_\epsilon(x, x'')} \;\in\; \mathrm{Mat}_4(\mathbb{C}).$$

Then:

(1) Existence.

There exists a Hilbert space $\mathcal{H}_{K^{(\epsilon)}}$ of $\mathbb{C}^4$–valued functions on the neighbourhood, called the (vector–valued) reproducing kernel Hilbert space (RKHS) of $K^{(\epsilon)}$, such that for all $u \in \mathbb{C}^4$ and x'' in the neighbourhood,

$$\begin{aligned} & K^{(\epsilon)}(\cdot, x'')\, u \in \mathcal{H}_{K^{(\epsilon)}}, \\ & \Big\langle F,\; K^{(\epsilon)}(\cdot, x'')\, u \Big\rangle_{\mathcal{H}_{K^{(\epsilon)}}} = u^\dagger F(x'') \quad \textit{(reproducing property).} \end{aligned} \tag{4.7}$$

(2) Inner product on finite spans.

On finite linear combinations $F = \sum_i K^{(\epsilon)}(\cdot, x_i) u_i$ and $G = \sum_j K^{(\epsilon)}(\cdot, y_j) v_j$,

$$\Big\langle F,\; G \Big\rangle_{\mathcal{H}_{K^{(\epsilon)}}} = \sum_{i,j} u_i^\dagger \, K^{(\epsilon)}(x_i, y_j)\, v_j.$$

The space $\mathcal{H}_{K^{(\epsilon)}}$ is the completion of these finite spans.

(3) Uniqueness.
$\mathcal{H}_{K^{(\epsilon)}}$ is unique up to canonical isometry: any other Hilbert space of $\mathbb{C}^4$–valued functions satisfying (1)–(2) is isometrically isomorphic to $\mathcal{H}_{K^{(\epsilon)}}$.

(4) Minimality.
$\mathcal{H}_{K^{(\epsilon)}}$ is the closed linear span of the sections $\{K^{(\epsilon)}(\cdot, x')u : \ x' \text{ near } x, \ u \in \mathbb{C}^4\}$.

Remark 4.35 (How this applies to our smeared inner product)**.** For $|\psi_j\rangle_x = \sum_\beta c_\beta^{(j)} |\beta\rangle_x$ define the constant vector–fields $\Phi^{(j)}(x') := \sqrt{\chi_\epsilon(x, x')}\, c^{(j)} \in \mathbb{C}^4$. Then, by construction and the reproducing formula in Theorem 4.34,

$$\langle \psi_1 | \psi_2 \rangle_x^{(\epsilon)} = \sum_{\alpha,\beta} \iint \overline{\Phi_\alpha^{(1)}(x')}\, K^{\alpha\beta}(x', x'')\, \Phi_\beta^{(2)}(x'')\, \mathrm{d}\mu(x')\, \mathrm{d}\mu(x'') \ = \ \left\langle \Phi^{(1)}, \ \Phi^{(2)} \right\rangle_{\mathcal{H}_{K^{(\epsilon)}}}.$$

Therefore $\langle \cdot | \cdot \rangle_x^{(\epsilon)}$ is a bona fide inner product on the image of $\psi \mapsto \Phi$, it is positive semidefinite, and the Cauchy–Schwarz inequality follows immediately from the Hilbert–space C–S inequality in $\mathcal{H}_{K^{(\epsilon)}}$. This is exactly the "RKHS argument" used in the proof of Proposition 4.38.

Remark 4.36 (Scalar reduction if preferred)**.** If one prefers to avoid vector–valued kernels, fix $c \in \mathbb{C}^4$ and consider the scalar kernel $K_c(x', x'') := c^\dagger K(x', x'')c$. The classical (scalar) Moore–Aronszajn theorem yields an RKHS (Reproducing Kernel Hilbert Space) $\mathcal{H}_{K_c}$ with reproducing property $\langle f, K_c(\cdot, x'') \rangle = f(x'')$. Applying this to all c recovers the vector–valued statement by polarization.

Remark 4.37 (References)**.** The scalar theorem is due to Aronszajn [370]. Vector–valued RKHS results in our form can be found in, e.g., [371].

Proposition 4.38 (Positivity and Cauchy–Schwarz for the smeared form)**.** *Suppose the kernel is of* positive type *near the diagonal in the sense that for all square–integrable test families $\{\phi_\alpha(\cdot)\}_{\alpha \in \{0,1,p,s\}}$ with support in a normal neighbourhood of x,*

$$\sum_{\alpha,\beta} \iint \overline{\phi_\alpha(x')} \left\langle \mathring{\mathbf{\Psi}} \right| \hat{G}_\Lambda^{\alpha\beta}(x', x'') \left| \mathring{\mathbf{\Psi}} \right\rangle \phi_\beta(x'')\, \mathrm{d}\mu(x')\, \mathrm{d}\mu(x'') \ \geq \ 0. \tag{4.8}$$

Then for every ψ, $\langle \psi | \psi \rangle_x^{(\epsilon)} \geq 0$, and the Cauchy–Schwarz inequality holds for the smeared form $\langle \cdot | \cdot \rangle_x^{(\epsilon)}$.

Proof. **Step 0: Notation and the scalar kernel.** Define the matrix–valued scalar kernel

$$K^{\alpha\beta}(x', x'') \ := \ \left\langle \mathring{\mathbf{\Psi}} \right| \hat{G}_\Lambda^{\alpha\beta}(x', x'') \left| \mathring{\mathbf{\Psi}} \right\rangle, \qquad \alpha, \beta \in \{0, 1, p, s\}.$$

By assumption (4.8), K is Hermitian and of positive type on a normal neighbourhood of x.

Step 1: Pointwise positivity on the diagonal (a.e.). Fix x_0 in the neighbourhood and let $\{\eta_\delta\}_{\delta > 0} \subset C_c^\infty$ be a standard approximate identity centred at x_0. For any $z \in \mathbb{C}^4$, choose test fields $\phi_\beta(x') := \eta_\delta(x')\, z_\beta$ in (4.8). Then

$$0 \leq \sum_{\alpha,\beta} \iint \overline{\eta_\delta(x') z_\alpha}\, K^{\alpha\beta}(x', x'')\, \eta_\delta(x'') z_\beta\, \mathrm{d}\mu(x')\, \mathrm{d}\mu(x'') = \iint \overline{\eta_\delta(x')}\, \eta_\delta(x'')\, z^\dagger K(x', x'') z\, \mathrm{d}\mu\, \mathrm{d}\mu.$$

Letting $\delta \to 0$ and using the local boundedness/continuity (from the positive–type hypothesis), we obtain $z^\dagger K(x_0, x_0) z \geq 0$ for almost every x_0 (Lebesgue points). Hence the 4×4 matrix $K(x', x')$ is positive semidefinite for a.e. x'.

Step 2: Positivity of the smeared quadratic form. Write $|\psi\rangle_x = \sum_\beta c_\beta \, |\beta\rangle_x$ and recall the smeared inner product

$$\langle \psi | \psi \rangle_x^{(\epsilon)} = \sum_{\alpha,\beta} \int \chi_\epsilon(x, x') \, \overline{c_\alpha} \, K^{\alpha\beta}(x, x') \, c_\beta \, \mathrm{d}\mu(x'),$$

where $\chi_\epsilon(x, \cdot)$ is an approximate identity at x (cf. Definition 4.31). Define the (a.e. positive semidefinite) matrix field $M(x') := K(x, x') = [K^{\alpha\beta}(x, x')]_{\alpha,\beta}$. By Step 1 applied at $x' = x$ (and by continuity near the diagonal), $M(x')$ is Hermitian and positive semidefinite for x' in a neighbourhood of x. Therefore, for any $c \in \mathbb{C}^4$,

$$\overline{c}^\dagger M(x') c \;\geq\; 0 \quad \text{for a.e. } x' \qquad \Longrightarrow \qquad \int \chi_\epsilon(x, x') \, \overline{c}^\dagger M(x') c \, \mathrm{d}\mu(x') \;\geq\; 0$$

(since $\chi_\epsilon \geq 0$ and $\int \chi_\epsilon = 1$). Thus $\langle \psi | \psi \rangle_x^{(\epsilon)} \geq 0$.

Step 3: Sesquilinearity and Hermiticity of the smeared form. Define, for $|\psi_j\rangle_x = \sum_\alpha c_\alpha^{(j)} |\alpha\rangle_x$ $(j = 1, 2)$,

$$\langle \psi_1 | \psi_2 \rangle_x^{(\epsilon)} := \sum_{\alpha,\beta} \int \chi_\epsilon(x, x') \, \overline{c_\alpha^{(1)}} \, K^{\alpha\beta}(x, x') \, c_\beta^{(2)} \, \mathrm{d}\mu(x').$$

Linearity in the second slot and conjugate linearity in the first are immediate; Hermiticity follows from $K^{\beta\alpha}(x', x) = \overline{K^{\alpha\beta}(x, x')}$.

Step 4: Cauchy–Schwarz inequality (two equivalent routes).
Route A: Finite-dimensional Gram form. Set

$$\mathbf{M}_\epsilon(x) \;:=\; \int \chi_\epsilon(x, x') \, M(x') \, \mathrm{d}\mu(x') \;\in\; \mathrm{Herm}(4).$$

By Step 2 and linearity, $\mathbf{M}_\epsilon(x)$ is Hermitian positive semidefinite. Then for $c^{(j)} \in \mathbb{C}^4$,

$$\langle \psi_1 | \psi_2 \rangle_x^{(\epsilon)} = \overline{c^{(1)}}^{\,\dagger} \, \mathbf{M}_\epsilon(x) \, c^{(2)}.$$

It is a standard fact for positive semidefinite Hermitian forms that $|\overline{u}^\dagger \mathbf{M} v|^2 \leq (\overline{u}^\dagger \mathbf{M} u)\,(\overline{v}^\dagger \mathbf{M} v)$. Hence

$$\left| \langle \psi_1 | \psi_2 \rangle_x^{(\epsilon)} \right|^2 \;\leq\; \langle \psi_1 | \psi_1 \rangle_x^{(\epsilon)} \; \langle \psi_2 | \psi_2 \rangle_x^{(\epsilon)}.$$

Route B: RKHS construction. Consider the vector–valued positive kernel

$$K^{(\epsilon)}(x', x'') \;:=\; \sqrt{\chi_\epsilon(x, x')} \, K(x', x'') \, \sqrt{\chi_\epsilon(x, x'')}.$$

By (4.8), $K^{(\epsilon)}$ is Hermitian and of positive type. By the Moore–Aronszajn theorem [370] (and its vector–valued extensions; see, e.g., [371]), there exists a reproducing kernel Hilbert

space $\mathcal{H}_{K^{(\epsilon)}}$ of $\mathbb{C}^4$-valued functions with inner product $\langle\cdot,\cdot\rangle_{K^{(\epsilon)}}$ reproducing $K^{(\epsilon)}$. For $|\psi_j\rangle_x = \sum_\beta c_\beta^{(j)}|\beta\rangle_x$ define $\Phi_\beta^{(j)}(x') := \sqrt{\chi_\epsilon(x,x')}\, c_\beta^{(j)}$. Then

$$\langle\psi_1|\psi_2\rangle_x^{(\epsilon)} = \sum_{\alpha,\beta}\iint \overline{\Phi_\alpha^{(1)}(x')}\, K^{\alpha\beta}(x',x'')\, \Phi_\beta^{(2)}(x'')\,\mathrm{d}\mu(x')\,\mathrm{d}\mu(x'') = \langle\Phi^{(1)},\Phi^{(2)}\rangle_{K^{(\epsilon)}}.$$

Cauchy–Schwarz follows immediately from the Hilbert-space C–S inequality in $\mathcal{H}_{K^{(\epsilon)}}$.

Step 5: Conclusion. Either route proves that $\langle\cdot|\cdot\rangle_x^{(\epsilon)}$ is a positive semidefinite Hermitian sesquilinear form and satisfies Cauchy–Schwarz:

$$\left|\langle\psi_1|\psi_2\rangle_x^{(\epsilon)}\right|^2 \;\le\; \langle\psi_1|\psi_1\rangle_x^{(\epsilon)}\;\langle\psi_2|\psi_2\rangle_x^{(\epsilon)}. \qquad \square$$

Proposition 4.39 (Recovery of the coincident inner product)**.** *Assume the hypotheses of Proposition 4.25 (thus the SOT limit exists):* $\lim_{x'\to x}\hat{G}_\Lambda^{\alpha\beta}(x,x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\hat{\mathcal{F}}_\beta(x)$*. Then for all* ψ_1,ψ_2*,*

$$\lim_{\epsilon\to 0}\langle\psi_1|\psi_2\rangle_x^{(\epsilon)} = \langle\psi_1|\psi_2\rangle_x \qquad \textit{(the coincident-limit inner product of Definition 4.20).}$$

Proof. Using Proposition 4.25, for each fixed ψ_1,ψ_2 the integrand $\langle\overset{\circ}{\boldsymbol{\Psi}}|\,\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]\,|\overset{\circ}{\boldsymbol{\Psi}}\rangle$ is continuous at $x'=x$. By (AI2) and dominated convergence (boundedness from Proposition 4.15), the smeared scalar converges to the point value at $x'=x$, which equals the coincident limit. $\square$

Proposition 4.40 (Independence of mollifier and stability)**.** *Let* $\{\chi_\epsilon\},\{\tilde{\chi}_\epsilon\}$ *be two approximate identities at* x*. Under the hypotheses of Proposition 4.39, one has*

$$\lim_{\epsilon\to 0}\left|\langle\psi_1|\psi_2\rangle_x^{(\epsilon)} - \langle\psi_1|\tilde{\psi}_2\rangle_x^{(\epsilon)}\right| = 0.$$

If, additionally, the kernel is of positive type (as in Proposition 4.38), then each $\langle\cdot|\cdot\rangle_x^{(\epsilon)}$ *is positive semidefinite and converges monotonically to the coincident-limit form whenever* χ_ϵ *increases pointwise to a delta net.*

Proof. Both nets converge to the same limit by Proposition 4.39. The monotone convergence statement follows from positivity of the scalar kernel and standard monotone convergence theorems. $\square$

Remark 4.41 (Choice of paths and gauge)**.** Replacing $\gamma_{x\leftarrow x'}$ by any other family with the same germ at the diagonal changes $\hat{G}_\Lambda^{(\epsilon)}(\mathfrak{B}_x)$ by $o(1)$ as $\epsilon\to 0$, provided the connection $\mathcal{A}$ is continuous; hence Proposition 4.39 is path-independent. By Proposition 4.33, the smeared inner products are gauge invariant for every ϵ, so the limiting fibre metric of Definition 4.20 is gauge invariant as well (cf. Remark 4.29).

Lemma 4.42 (Coincident Gram matrix is positive)**.** *Assume Assumption 4.21 and the strong coincident limit of Proposition 4.25. Then for each* x *and any coefficients* z_α*,*

$$\sum_{\alpha,\beta\in\mathcal{I}}\overline{z_\alpha}\,z_\beta\left\langle\overset{\circ}{\boldsymbol{\Psi}}\right|\hat{G}_\Lambda^{\alpha\beta}(x,x)\left|\overset{\circ}{\boldsymbol{\Psi}}\right\rangle \;\ge\; 0.$$

Proof. By Proposition 4.25, $\hat{G}^{\alpha\beta}_{\Lambda}(x,x) = \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\hat{\mathcal{F}}_{\beta}(x)$ in SOT. Let $F_x(z) := \sum_{\beta\in\mathcal{I}} z_\beta\,\hat{\mathcal{F}}_\beta(x)$. Then

$$\sum_{\alpha,\beta} \overline{z_\alpha} z_\beta \,\langle \mathring{\mathbf{\Psi}}|\, \hat{G}^{\alpha\beta}_{\Lambda}(x,x)\,|\mathring{\mathbf{\Psi}}\rangle = \Big\langle \mathring{\mathbf{\Psi}}\Big|\, F_x(z)^{\dagger} F_x(z)\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle = \Big\|F_x(z)\,|\mathring{\mathbf{\Psi}}\rangle\Big\|^2 \;\geq\; 0,$$

using the GNS anchoring (Proposition 4.17). □

Corollary 4.43 (Positivity condition, formalized)**.** *The "Positivity condition" paragraph holds as a corollary of Lemma 4.42. In particular, the coincident Gram matrix* $\big[\langle\mathring{\mathbf{\Psi}}|\hat{G}^{\alpha\beta}_{\Lambda}(x,x)|\mathring{\mathbf{\Psi}}\rangle\big]$ *is positive semidefinite.*

Corollary 4.44 (Ontological orthonormality from the emergent metric)**.** *With the emergent inner product of Definition 4.20 well defined (Proposition 4.28) and the Gram matrix positive (Lemma 4.42), there exist unit representatives* $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ *of the rays* $\mathcal{R}_x(\mathring{\boldsymbol{\alpha}})$ *such that* $\langle\alpha|\beta\rangle_x = \delta_{\alpha\beta}$*. Moreover, any two such choices differ by a unique unitary in* $\mathrm{U}(4)$*.*

Proof. This is precisely Proposition 4.10 (Gram factorization/Cholesky at x), restated. □

Remark 4.45 (Fourfold structure, restrictions, and couplings)**.** The Fourfold correlator $\hat{\mathbf{G}}_\Lambda(x,x')$ (cf. Definition 4.9) packages, in a single 4×4 kernel, the symmetry/antisymmetry relations, parasymmetric coherence, and holosymmetric (history-level) structure prescribed by the Fourfold Dialectic Algebra (Chapter 1; Definitions 1.16 and 1.23 and Lemma 1.20). In the mode-ordered basis $\mathcal{I} = \{0,1,p,s\}$ it admits the block decomposition

$$\hat{\mathbf{G}}_\Lambda(x,x') \;=\; \begin{pmatrix} \hat{\mathbf{G}}_{(0,1)}(x,x') & \hat{\mathbf{G}}_{(0,1)\leftrightarrow(p,s)}(x,x') \\ \hat{\mathbf{G}}_{(p,s)\leftrightarrow(0,1)}(x,x') & \hat{\mathbf{G}}_{(p,s)}(x,x') \end{pmatrix},$$

where the top-left block $\hat{\mathbf{G}}_{(0,1)}(x,x')$ is precisely the Twofold correlator (Definition 4.1) and this identification is formalised in Proposition 4.7. The off-diagonal blocks encode the $\{0,1\}\leftrightarrow\{p,s\}$ couplings responsible for *parasymmetric* and *holosymmetric* amplitudes, consistent with the corner–mode correspondences Sym $\leftrightarrow$ Th, AntiSym $\leftrightarrow$ AntiTh, ParaSym $\leftrightarrow$ SynTh, HoloSym $\leftrightarrow$ HoloTh (Chapter 1; cf. Sections 1.2.1 to 1.2.4).

From a structural standpoint, Proposition 4.13 enforces reciprocity between blocks under $(x,x')\leftrightarrow(x',x)$, and Proposition 4.14 guarantees that the entire block matrix transforms bi-covariantly $g(x)\cdot g(x')^{\dagger}$, so that Born evaluations and the coincident-limit fibre metric of Definition 4.20 are gauge invariant (see also Remark 4.29). Operationally, the holosymmetric content of the bottom-right and off-diagonal blocks is realised in the control–register readouts of the master holosymmetric operator (Chapter 3; Section 3.8.3 and Corollary 3.21), and these same blocks are the carriers of the nonlocal amplitudes that drive the emergent inner product and orthonormal frame construction in Proposition 4.10.

Basis and dialectic roles.

Definition 4.46 (Fourfold modal basis and dialectic roles)**.** Fix $x\in\mathcal{X}_q$. After the fibre inner product is defined by (4.6), choose unit representatives of the realised rays $\mathcal{R}_x(\mathring{\boldsymbol{\alpha}})\subset\mathbb{P}(\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}})$, $\mathring{\boldsymbol{\alpha}}\in\mathfrak{M} = \{\mathring{\mathbf{0}},\mathring{\mathbf{1}},\mathring{\mathbf{p}},\mathring{\mathbf{s}}\}$, to form the ordered basis

$$\mathcal{B}_x := \{|0\rangle_x,\,|1\rangle_x,\,|p\rangle_x,\,|s\rangle_x\}\subset\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}\cong\mathbb{C}^4, \qquad \text{ordered as } \{0,1,p,s\}.$$

By Proposition 4.10, $\mathcal{B}_x$ can be chosen orthonormal and is unique up to a diagonal unitary (phase) in $\mathrm{U}(1)^4$. Write the rank-one projectors $\Pi_\alpha^{(x)} := |\alpha\rangle_x\langle\alpha|$ for $\alpha \in \{0, 1, p, s\}$, and the Twofold projector $\Pi_{(0,1)}^{(x)} := \Pi_0^{(x)} + \Pi_1^{(x)}$.

Dialectic roles (via the symmetry prism and bridge). Consistently with the Fourfold Dialectic Algebra and symmetry–corner congruence (Chapter 1; Definitions 1.16 and 1.23 and Lemma 1.20):

- $|0\rangle_x$ (*Symmetry*): identity/coherence within the dyad $\{0, 1\}$.
- $|1\rangle_x$ (*Antisymmetry*): difference/tension within the dyad $\{0, 1\}$.
- $|p\rangle_x$ (*Parasymmetry*): an emergent mode capturing coherent composition across the dyad.
- $|s\rangle_x$ (*Holosymmetry*): a system-level, implementation-invariant mode (operationally read out via the holosymmetric effect; cf. eq. (3.36)).

With this basis, the Fourfold correlator $\hat{\mathbf{G}}_\Lambda(x, x')$ (Chapter 4; Definition 4.9) admits the block form indexed by $\{0, 1, p, s\}$; its restriction to $\{0, 1\}$ recovers the Twofold correlator $\hat{\mathbf{G}}_{(0,1)}(x, x')$ (Definition 4.1 and Proposition 4.7), while off-diagonal blocks encode the parasymmetric/holosymmetric couplings that drive emergent geometry.

Remark 4.47 (Twofold equal-superposition effect vs. parasymmetric basis state)**.** The equal-superposition vector in the Twofold sector,

$$|+\rangle_x := \tfrac{1}{\sqrt{2}}\big(|0\rangle_x + |1\rangle_x\big), \qquad P_{\text{para}}^{(x)} := |+\rangle_x\langle+|,$$

defines the *local parasymmetric effect* inside $\mathrm{span}\{|0\rangle_x, |1\rangle_x\}$ but is *not* identified with the Fourfold basis vector $|p\rangle_x$ (cf. Definition 2.94). Likewise, $|s\rangle_x$ is not assumed to be any linear combination of $|0\rangle_x, |1\rangle_x$; its operational meaning comes via the holosymmetric effect (eq. (3.36)). This separation ensures that ordinary interference within $\{0, 1\}$ and higher-order relational phenomena through $\{p, s\}$ coexist without conflating effects with basis states, while the Fourfold correlator furnishes the common relational kernel linking them (cf. Section 4.1.2).

4.1.3 Emergent Hilbert geometry from the Fourfold correlator

The formalism begins with the Quantum Holo-State $\omega^{\mathring{\Psi}}$ on the observable C^*-algebra $\mathcal{A}$. By the Gelfand–Naimark–Segal construction (cf. Definition 1.34), this state yields a cyclic representation

$$\big(\pi_{\mathring{\Psi}},\ \mathcal{H}_{\mathring{\Psi}},\ |\Omega_{\omega^{\mathring{\Psi}}}\rangle\big),$$

and one identifies the *emergent Hilbert space* as

$$\mathcal{H}_{\text{em}} \equiv \mathcal{H}_{\mathring{\Psi}}.$$

In what follows, hatted objects denote represented operators on $\mathcal{H}_{\text{em}}$ (the GNS representation), per Proposition 4.17: $\hat{\mathcal{F}}_\alpha := \pi_{\mathring{\Psi}}(\mathcal{F}_\alpha)$ and $\hat{G}_\Lambda^{\alpha\beta} := \pi_{\mathring{\Psi}}(G_\Lambda^{\alpha\beta})$; state recovery is given by

$\omega^{\mathring{\Psi}}(A) = \langle\Omega|\hat{A}|\Omega\rangle$ (cf. eq. (4.5)). If some field modes are unbounded, they are assumed densely defined and closable on a common core (standard in the GNS setting).

Each locus x (a Primordial Quantum Singularity, PQS) carries a *modal fiber* $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ whose inner product is *not* postulated a priori. Instead, the inner product is *generated* from the Fourfold Inter-Modal Correlator $\hat{\mathbf{G}}_\Lambda(x,x') = [\hat{G}_\Lambda^{\alpha\beta}(x,x')]_{\alpha,\beta\in\{0,1,p,s\}}$ (see Definition 4.9) by taking the Holo-State expectation in the coincident limit:

$$\langle\psi_1|\psi_2\rangle_x := \lim_{x'\to x} \Big\langle \mathring{\mathbf{\Psi}}\Big| \hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle, \qquad \text{cf. } eq.\ (4.6). \tag{4.9}$$

Here ψ_1^* indicates the conjugate-linear dependence in the first slot (equivalently, conjugation of local coefficients), consistent with the sesquilinearity properties of the correlator ($\{0,1\}$- and Fourfold versions: Propositions 4.2 and 4.12). Under the continuity hypotheses on selectors and transport, the correlator admits a controlled coincident limit $\lim_{x'\to x}\hat{G}_\Lambda^{\alpha\beta}(x,x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\hat{\mathcal{F}}_\beta(x)$ in SOT (hence WOT) and is WOT–continuous in both endpoints (Proposition 4.25), which ensures that $\langle\cdot|\cdot\rangle_x$ is well defined, positive semidefinite, and satisfies Cauchy–Schwarz; the quotient by its null space and completion yields the Hilbert fiber $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ (see Proposition 4.28). Thus, $\mathcal{H}_{\mathrm{em}}$ (from GNS) is the representation space *in which the correlator lives*, while the correlator's Holo-State expectations *forge the metric* on each local modal fiber.

Algebraically, the Fourfold correlator is a 4×4 operator-valued kernel over the dialectic modes $\{0,1,p,s\}$ (Chapter 1 background: Definitions 1.16 and 1.23 and Lemma 1.20; Born semantics: Definition 1.18). Diagonal entries $\hat{G}_\Lambda^{\alpha\alpha}$ encode *modal persistence*; off-diagonal entries $\hat{G}_\Lambda^{\alpha\beta}$ ($\alpha\neq\beta$) encode *modal transitions/interference*. The top-left 2×2 block $\hat{\mathbf{G}}_{(0,1)}(x,x')$ recovers the Symmetry/Antisymmetry (Thesis/Antithesis) sector, and is *precisely* the restriction stated in Proposition 4.7 (cf. the refined Twofold definition Definition 4.1); the remaining blocks quantify couplings to Parasymmetry (Synthesis) and Holosymmetry (Holothesis), with operational effects referenced in Definition 2.94 and eq. (3.36). Gauge covariance of the entire block kernel is given by Proposition 4.14, ensuring that Born evaluations and the coincident-limit metric $\langle\cdot|\cdot\rangle_x$ are gauge invariant (see Remark 4.29).

In this sense, the Fourfold correlator is the *relational kernel* that both transports and couples the four logical facets—via the path-ordered transporter $\mathcal{U}$ (Chapter 4 transport: eqs. (4.11) and (4.14)) and the selector fields—and, through eq. (4.6), *generates* the Hilbert geometry on which those facets are read. For distributional or singular settings, the point-splitting/smearing scheme in Definitions 4.31 and 4.32 and Propositions 4.38 and 4.39 preserves gauge covariance and positivity, providing a robust route to the same emergent metric.

4.1.4 Parallel Transport Between PQS Loci

Definition 4.48 (Path-ordered parallel transport and pullback generator)**.** Let $\mathcal{X}_q$ be the emergent configuration space and let $\mathcal{A}\in\Omega^1\big(\mathcal{X}_q,\ \mathfrak{u}(\mathcal{H}_{\mathrm{em}})\big)$ be a (skew-Hermitian) unitary connection one-form on the trivial bundle $\mathcal{X}_q\times\mathcal{H}_{\mathrm{em}}\to\mathcal{X}_q$. For any piecewise C^1 path

$\gamma : [s_0, s_1] \to \mathcal{X}_q$ with $\gamma(s_0) = x'$ and $\gamma(s_1) = x$, define the *pullback generator* along γ by

$$\begin{aligned} A_\gamma(s) &:= (\gamma^*\mathcal{A})_s\big(\dot\gamma(s)\big) \\ &\in \mathfrak{u}(\mathcal{H}_{\mathrm{em}})\,, \end{aligned} \tag{4.10}$$

and the *parallel transporter* from x' to x along γ by the path-ordered exponential

$$\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{P}\,\exp\Big(-\int_\gamma \mathcal{A}\Big) = \mathcal{P}\,\exp\Big(-\int_{s_0}^{s_1} A_\gamma(s)\,ds\Big) \;\in\; \mathrm{U}(\mathcal{H}_{\mathrm{em}}). \tag{4.11}$$

Equivalently (cf. Definition 4.49), $\mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma)$ is the unique strongly continuous solution of

$$\frac{d}{ds}\,\mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma) = -A_\gamma(s)\,\mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma), \qquad \mathcal{U}(\gamma(s_0) \leftarrow \gamma(s_0); \gamma) = \mathbf{1}.$$

By the skew-Hermitian convention $A_\gamma(s)^\dagger = -A_\gamma(s)$, the transporter is unitary (Lemma 4.50); it is invariant under monotone reparametrizations of γ and obeys composition/inversion as in Proposition 4.52. Under a gauge change $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, $\mathcal{A} \mapsto g\,\mathcal{A}\,g^\dagger + g\,\mathrm{d}g^\dagger$ and $\mathcal{U}(x \leftarrow x'; \gamma) \mapsto g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^\dagger$ (Proposition 4.54).

Definition 4.49 (ODE characterization of parallel transport)**.** Equivalently to the path-ordered definition in Definition 4.48, the parallel transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ is the unique strongly continuous solution of the initial–value problem

$$\frac{d}{ds}\,\mathcal{U}\big(\gamma(s) \leftarrow \gamma(s_0); \gamma\big) \;=\; -\,A_\gamma(s)\,\mathcal{U}\big(\gamma(s) \leftarrow \gamma(s_0); \gamma\big), \qquad \mathcal{U}\big(\gamma(s_0) \leftarrow \gamma(s_0); \gamma\big) = \mathbf{1}, \tag{4.12}$$

where $A_\gamma(s) = (\gamma^*\mathcal{A})_s(\dot\gamma(s)) \in \mathfrak{u}(\mathcal{H}_{\mathrm{em}})$ (cf. eq. (4.10)). In particular, since $A_\gamma(s)^\dagger = -A_\gamma(s)$,

$$\frac{d}{ds}\big(\mathcal{U}^\dagger\mathcal{U}\big) = \mathcal{U}^\dagger A_\gamma^\dagger \mathcal{U} + \mathcal{U}^\dagger(-A_\gamma)\mathcal{U} = 0,$$

and with the initial condition $\mathcal{U}(\gamma(s_0) \leftarrow \gamma(s_0); \gamma) = \mathbf{1}$, the transporter is unitary for all s (see also Lemma 4.50).

Lemma 4.50 (Unitarity and reparametrization invariance)**.** *Let $\mathcal{A} \in \Omega^1(\mathcal{X}_q, \mathfrak{u}(\mathcal{H}_{\mathrm{em}}))$ and let $A_\gamma(s) := (\gamma^*\mathcal{A})_s(\dot\gamma(s))$ so that $A_\gamma(s)^\dagger = -A_\gamma(s)$ (eq. (4.10)). Then the solution $\mathcal{U}$ of the initial–value problem*

$$\frac{d}{ds}\,\mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma) = -A_\gamma(s)\,\mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma), \qquad \mathcal{U}(\gamma(s_0) \leftarrow \gamma(s_0); \gamma) = \mathbf{1} \tag{4.13}$$

is unitary for all s, and is invariant under monotone C^1 reparametrizations of γ.

Proof. We split the argument into two parts.

(a) Unitarity from skew–Hermitian generator. Set $U(s) := \mathcal{U}(\gamma(s) \leftarrow \gamma(s_0); \gamma)$. For any $v, w \in \mathcal{H}_{\mathrm{em}}$,

$$\begin{aligned} \frac{d}{ds}\,\langle U(s)v,\, U(s)w\rangle &= \langle -A_\gamma(s)U(s)v,\, U(s)w\rangle + \langle U(s)v,\, -A_\gamma(s)U(s)w\rangle \\ &= \langle U(s)v,\, (A_\gamma(s)^\dagger - A_\gamma(s))U(s)w\rangle \\ &= 0, \end{aligned}$$

because $A_\gamma(s)^\dagger = -A_\gamma(s)$ by assumption. Hence $\langle U(s)v, U(s)w\rangle$ is constant in s. With $U(s_0) = \mathbf{1}$, we obtain $\langle U(s)v, U(s)w\rangle = \langle v, w\rangle$ for all s, i.e. $U(s)$ is an isometry. By the same evolution run backward in s (or equivalently by eq. (4.14)), $U(s)$ is invertible with inverse $U(s)^{-1} = \mathcal{U}(\gamma(s_0) \leftarrow \gamma(s); \gamma)$. Thus $U(s)$ is unitary for all s. This also agrees with the path–ordered exponential formula in eq. (4.11), since the exponential of a skew–Hermitian element is unitary and time ordering preserves unitarity at each Dyson–series truncation.

(b) Invariance under monotone reparametrization. Let $\sigma : [t_0, t_1] \to [s_0, s_1]$ be C^1 and strictly increasing, and consider the reparametrized path $\tilde\gamma := \gamma \circ \sigma$ with $\tilde\gamma(t_0) = \gamma(s_0) = x'$ and $\tilde\gamma(t_1) = \gamma(s_1) = x$. Define $V(t) := \mathcal{U}(\tilde\gamma(t) \leftarrow \tilde\gamma(t_0); \tilde\gamma)$. By eq. (4.12), V satisfies

$$\frac{d}{dt} V(t) = -A_{\tilde\gamma}(t)\, V(t) \quad \text{with} \quad A_{\tilde\gamma}(t) = (\tilde\gamma^* \mathcal{A})_t(\dot{\tilde\gamma}(t)) = A_\gamma(\sigma(t))\, \sigma'(t), \qquad V(t_0) = \mathbf{1}.$$

Now set $W(t) := \mathcal{U}(\gamma(\sigma(t)) \leftarrow \gamma(\sigma(t_0)); \gamma)$. Differentiating and using eq. (4.12) along γ together with the chain rule,

$$\frac{d}{dt} W(t) = -A_\gamma(\sigma(t))\, \sigma'(t)\, W(t), \qquad W(t_0) = \mathbf{1}.$$

Thus V and W solve the same linear ODE with the same initial data; by uniqueness of solutions for strongly continuous operator–valued ODEs, $V(t) = W(t)$ for all t. Evaluating at t_1 yields

$$\mathcal{U}(x \leftarrow x'; \tilde\gamma) = V(t_1) = W(t_1) = \mathcal{U}(x \leftarrow x'; \gamma).$$

Equivalently, in the ordered–exponential representation *eq.* (4.11),

$$\mathcal{P} \exp\!\Big(-\int_{t_0}^{t_1} A_\gamma(\sigma(t))\, \sigma'(t)\, dt \Big) = \mathcal{P} \exp\!\Big(-\int_{s_0}^{s_1} A_\gamma(s)\, ds \Big),$$

since σ is order preserving. (If σ is strictly decreasing, then the parameter order is reversed and one obtains $\mathcal{U}(x \leftarrow x'; \gamma \circ \sigma) = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$ in agreement with inversion in eq. (4.14).)

Combining (a) and (b) gives the stated unitarity and reparametrization invariance. This lemma is consistent with (and used by) the Fourfold channel covariance and Hermitian symmetry (Corollary 4.64 and Lemma 4.66) and with the global functorial properties of transport in Proposition 4.52. □

Remark 4.51 (Meaning and consequences of Lemma 4.50)**.** The lemma asserts two independent but complementary facts about the transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ defined in Definitions 4.48 and 4.49.

(i) Unitarity = fibrewise isometry. Because the pullback generator is skew–Hermitian ($A_\gamma^\dagger = -A_\gamma$, eq. (4.10)), the solution of the evolution eq. (4.13) satisfies

$$\langle \mathcal{U}(\gamma(s) \leftarrow \gamma(s_0))v, \mathcal{U}(\gamma(s) \leftarrow \gamma(s_0))w\rangle = \langle v, w\rangle \quad \text{for all } v, w \in \mathcal{H}_{\mathrm{em}}.$$

Thus $\mathcal{U}$ preserves norms and inner products along the path, so it is invertible with $\mathcal{U}^\dagger = \mathcal{U}^{-1}$. In geometric terms, $\mathcal{U}$ is *metric-compatible* with the emergent fibre inner product and is consistent with the covariant Leibniz rule for pairings (cf. eq. (4.105) upstream in Chapter 4).

(ii) Reparametrization invariance = dependence only on the oriented image of γ. If σ is a monotone C^1 reparametrization, then

$$\mathcal{U}(x \leftarrow x'; \gamma \circ \sigma) = \mathcal{U}(x \leftarrow x'; \gamma) \quad \text{when } \sigma' > 0,$$

so the transporter is insensitive to "speed" along the path; only the *geometric trace* of γ matters. If $\sigma' < 0$ (orientation-reversing), then $\mathcal{U}(x \leftarrow x'; \gamma \circ \sigma) = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$, which, together with unitarity, yields the standard adjoint/inverse relation captured explicitly in Proposition 4.52 and eq. (4.15).

Consequences.

(a) *Stable composition laws.* Since reparametrizations do not change $\mathcal{U}$, one may freely subdivide or concatenate path segments without affecting endpoint transports, which is used in the proof of Proposition 4.52 and eq. (4.14).

(b) *Gauge stability.* These properties persist under gauge changes by Proposition 4.54 and eq. (4.16) because endpoint conjugation preserves unitarity and commutes with reparametrizations.

(c) *Channel symmetry and Born invariance.* Applied to the Fourfold channel $\hat{G}_\Lambda^{\alpha\beta}(x, x')$ (Definition 4.61), unitarity and path reversal give $\left(\hat{G}_\Lambda^{\alpha\beta}(x, x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x)$ (Lemma 4.66); together with Corollary 4.64 this ensures that Born expectations formed from these channels are gauge invariant and independent of time-slicings of γ.

In short, Lemma 4.50 guarantees that parallel transport is an isometric, gauge-stable, and parameterization-agnostic way to compare fibre data along paths, which is foundational for all channel and correlator constructions used in Chapters 1–3 and upstream in Chapter 4.

Proposition 4.52 (Functoriality: composition and inversion)**.** *For composable paths $\gamma_1 : x \leftarrow y$ and $\gamma_2 : y \leftarrow x'$, the transporter satisfies*

$$\mathcal{U}(z \leftarrow x; \gamma_2 \circ \gamma_1) = \mathcal{U}(z \leftarrow y; \gamma_2)\, \mathcal{U}(y \leftarrow x; \gamma_1), \tag{4.14}$$

and

$$\mathcal{U}(x \leftarrow x'; \gamma)^{-1} = \mathcal{U}(x' \leftarrow x; \gamma^{-1}). \tag{4.15}$$

Proof. We give a proof directly from the defining ODE (4.12) and, in parallel, from the path-ordered exponential (4.11). Reparametrization invariance from Lemma 4.50 is used to place all paths on a single parameter interval.

(i) Composition. Without loss of generality (by Lemma 4.50) reparametrize so that $\gamma_2 : [0, s_*] \to \mathcal{X}_q$ runs from x' to y and $\gamma_1 : [s_*, 1] \to \mathcal{X}_q$ runs from y to x; define the concatenation $\gamma := \gamma_1 \circ \gamma_2 : [0, 1] \to \mathcal{X}_q$. Let A_γ be the piecewise pullback generator (4.10); then the transporter $U(s) := \mathcal{U}(\gamma(s) \leftarrow \gamma(0); \gamma)$ solves

$$\frac{d}{ds} U(s) = -A_\gamma(s)\, U(s), \qquad U(0) = \mathbf{1},$$

with $A_\gamma(s) = A_{\gamma_2}(s)$ for $s \in [0, s_*]$ and $A_\gamma(s) = A_{\gamma_1}(s)$ for $s \in [s_*, 1]$.

First segment. On $[0, s_*]$ the unique solution is $U(s) = \mathcal{U}(\gamma_2(s) \leftarrow \gamma_2(0); \gamma_2)$. In particular, $U(s_*) = \mathcal{U}(y \leftarrow x'; \gamma_2)$.

Second segment. On $[s_*, 1]$, consider the initial-value problem

$$\frac{d}{ds} V(s) = -A_{\gamma_1}(s)\, V(s), \qquad V(s_*) = \mathbf{1},$$

whose solution is $V(s) = \mathcal{U}(\gamma_1(s) \leftarrow \gamma_1(s_*); \gamma_1)$. Then the product

$$W(s) := V(s)\, U(s_*) = \mathcal{U}(\gamma_1(s) \leftarrow \gamma_1(s_*); \gamma_1)\, \mathcal{U}(y \leftarrow x'; \gamma_2)$$

satisfies $\frac{d}{ds} W(s) = -A_{\gamma_1}(s)\, W(s)$ and $W(s_*) = U(s_*)$. By uniqueness of solutions to (4.12), $U(s) = W(s)$ for all $s \in [s_*, 1]$. Evaluating at $s = 1$ gives the composition law

$$\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{U}(x \leftarrow y; \gamma_1)\, \mathcal{U}(y \leftarrow x'; \gamma_2).$$

Ordered-exponential view. Using (4.11) with the split integral $\int_0^1 A_\gamma = \int_{s_*}^1 A_{\gamma_1} + \int_0^{s_*} A_{\gamma_2}$ and time ordering (later times placed left), one obtains directly

$$\mathcal{P} \exp\Big(-\int_0^1 A_\gamma\Big) = \mathcal{P} \exp\Big(-\int_{s_*}^1 A_{\gamma_1}\Big)\, \mathcal{P} \exp\Big(-\int_0^{s_*} A_{\gamma_2}\Big),$$

which is exactly the same composition identity.

(ii) Inversion / path reversal. Let $\gamma^{-1}(s) := \gamma(1 - s)$ denote the reversed path (again after reparametrization to $[0, 1]$). Then $\dot\gamma^{-1}(s) = -\dot\gamma(1 - s)$, hence $A_{\gamma^{-1}}(s) = (\gamma^{-1})^* \mathcal{A}(\dot\gamma^{-1}(s)) = -A_\gamma(1 - s)$ by linearity and (4.10). Consider $V(s) := \mathcal{U}(\gamma(0) \leftarrow \gamma(s); \gamma)$. Differentiating and using (4.12),

$$\frac{d}{ds} V(s) = V(s)\, A_\gamma(s), \qquad V(0) = \mathbf{1}.$$

Define $W(s) := \mathcal{U}(\gamma^{-1}(s) \leftarrow \gamma^{-1}(0); \gamma^{-1})$, which solves $\frac{d}{ds} W(s) = -A_{\gamma^{-1}}(s)\, W(s) = A_\gamma(1 - s)\, W(s)$ with $W(0) = \mathbf{1}$. By the change of variable $t = 1 - s$, uniqueness implies $W(1) = V(1)^{-1}$. Evaluating at the endpoints yields

$$\mathcal{U}(x' \leftarrow x; \gamma^{-1}) = W(1) = V(1)^{-1} = \mathcal{U}(x \leftarrow x'; \gamma)^{-1}.$$

Equivalently, from (4.11) and $\big(\mathcal{P} e^{\int M}\big)^\dagger = \widetilde{\mathcal{P}}\, e^{\int M^\dagger}$ (reverse ordering), together with $A_\gamma^\dagger = -A_\gamma$ and Lemma 4.50, one gets $\mathcal{U}(x \leftarrow x'; \gamma)^\dagger = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$. Since $\mathcal{U}$ is unitary by Lemma 4.50, the adjoint equals the inverse, proving the claim. □

Remark 4.53 (Meaning of Proposition 4.52)**.** The identities eqs. (4.14) and (4.15) articulate that parallel transport is a *functor* from the path groupoid of $\mathcal{X}_q$ (objects: points; morphisms: piecewise C^1 paths modulo monotone reparametrization) to the unitary group on the fibre Hilbert space:

$$\Pi_1(\mathcal{X}_q) \longrightarrow \mathrm{U}(\mathcal{H}_{\mathrm{em}}), \qquad \gamma \longmapsto \mathcal{U}(x \leftarrow x'; \gamma).$$

Here $\mathcal{U}$ is the transporter of Definitions 4.48 and 4.49.

(i) Composition = concatenation. Given composable paths $\gamma_1 : x \leftarrow y$ and $\gamma_2 : y \leftarrow x'$, functoriality says that transport along the concatenation equals the product of transports:

$$\mathcal{U}(z \leftarrow x; \gamma_2 \circ \gamma_1) = \mathcal{U}(z \leftarrow y; \gamma_2)\,\mathcal{U}(y \leftarrow x; \gamma_1) \quad \text{(eq. (4.14))}.$$

Consequently, *slicings* of a path into subsegments do not change the endpoint transporter; this is the algebraic expression of reparametrization invariance (Lemma 4.50) in the presence of path concatenation.

(ii) Inversion = path reversal. Reversing the orientation of a path inverts the transporter:

$$\mathcal{U}(x \leftarrow x'; \gamma)^{-1} = \mathcal{U}(x' \leftarrow x; \gamma^{-1}) \quad \text{(eq. (4.15))}.$$

Together with unitarity (Lemma 4.50) this yields $\mathcal{U}(x \leftarrow x'; \gamma)^\dagger = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$.

(iii) Identities and associativity. Taking γ_1 (or γ_2) to be the constant path shows $\mathcal{U}(x \leftarrow x; \mathrm{id}_x) = \mathbf{1}$. Associativity of operator composition matches associativity of path concatenation, so transports along multi-segment paths are unambiguous.

(iv) Gauge compatibility. The functorial laws commute with gauge transformations $\mathcal{U} \mapsto g(x)\,\mathcal{U}\,g(x')^\dagger$ (Proposition 4.54 and eq. (4.16)), since endpoint conjugation distributes over products and inverses. Hence functoriality is gauge-stable.

(v) Relation to curvature and holonomy. For loops ℓ based at x, composition identifies the holonomy map $\ell \mapsto \mathrm{Hol}_\ell(x) = \mathcal{U}(x \leftarrow x; \ell)$ (Definition 4.56 and eq. (4.18)) as a group homomorphism from the fundamental group (up to thin homotopy) into $\mathrm{U}(\mathcal{H}_{\mathrm{em}})$. When $\mathcal{F} = 0$ on a simply connected domain, Proposition 4.59 shows the functor factors through endpoints, making $\mathcal{U}(x \leftarrow x'; \gamma)$ a pure gauge $g(x)g(x')^\dagger$.

(vi) Consequences for channels and correlators. For the Fourfold channel $\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x')$ (Definition 4.61), composition gives a natural *factorization* through an intermediate locus y:

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') = \sum_{\gamma \in \{0,1,p,s\}} \Big[\hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow y; \gamma_1)\,\hat{\mathcal{F}}_\gamma(y)\Big]\Big[\hat{\mathcal{F}}_\gamma^\dagger(y)\,\mathcal{U}(y \leftarrow x'; \gamma_2)\,\hat{\mathcal{F}}_\beta(x')\Big],$$

and inversion implies the Hermitian symmetry $(\hat{G}_\Lambda^{\alpha\beta}(x, x'))^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x)$ (Lemma 4.66). Both statements are compatible with gauge covariance (Corollary 4.64) because endpoint conjugation respects products and adjoints.

In summary, Proposition 4.52 formalizes the idea that parallel transport respects the *algebra* of paths: concatenation corresponds to operator multiplication, reversal to taking inverses (and hence adjoints). This functorial structure underpins the well-posed assembly of channel kernels and holonomy-based quantities throughout Chapters 1–3 and upstream in Chapter 4.

Proposition 4.54 (Gauge covariance of the connection and transporter)**.** *Under a local gauge* $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$,

$$\mathcal{A} \;\mapsto\; \mathcal{A}' \;:=\; g\,\mathcal{A}\,g^\dagger + g\,\mathrm{d}g^\dagger, \qquad \mathcal{U}(x \leftarrow x'; \gamma) \;\mapsto\; \mathcal{U}'(x \leftarrow x'; \gamma) \;:=\; g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^\dagger. \tag{4.16}$$

Proof. We prove the transporter law from the defining ODE eq. (4.12) and then note the equivalent statement in the path-ordered form eq. (4.11). Let $\gamma : [s_0, s_1] \to \mathcal{X}_q$ be C^1 with $\gamma(s_0) = x'$, $\gamma(s_1) = x$. Write

$$A_\gamma(s) := (\gamma^*\mathcal{A})_s(\dot\gamma(s)) \in \mathfrak{u}(\mathcal{H}_{\mathrm{em}}), \qquad G(s) := g(\gamma(s)) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}}).$$

Then the pulled-back, gauge-transformed generator is

$$A'_\gamma(s) \;:=\; (\gamma^*\mathcal{A}')_s(\dot\gamma(s)) \;=\; G(s)\,A_\gamma(s)\,G(s)^\dagger \;+\; \Big(\gamma^*(g\,\mathrm{d}g^\dagger)\Big)_s(\dot\gamma(s)).$$

Because g is unitary, $g^\dagger g = \mathbf{1} \Rightarrow \mathrm{d}g^\dagger\, g + g^\dagger \mathrm{d}g = 0$, and along γ one has $\Big(\gamma^*(g\,\mathrm{d}g^\dagger)\Big)_s(\dot\gamma(s)) = G(s)\,\partial_s G(s)^\dagger = -\,\partial_s G(s)\,G(s)^\dagger$. Hence

$$A'_\gamma(s) \;=\; G(s)\,A_\gamma(s)\,G(s)^\dagger \;-\; \partial_s G(s)\,G(s)^\dagger. \tag{$\star$}$$

Let $U(s) := \mathcal{U}(\gamma(s) \leftarrow \gamma(s_0);\gamma)$ solve $\frac{d}{ds}U(s) = -A_\gamma(s)U(s)$, $U(s_0) = \mathbf{1}$ (eq. (4.12)). Define

$$\widetilde{U}(s) \;:=\; G(s)\,U(s)\,G(s_0)^\dagger.$$

Then $\widetilde{U}(s_0) = \mathbf{1}$, and

$$\frac{d}{ds}\widetilde{U}(s) = \partial_s G(s)\,U(s)\,G(s_0)^\dagger + G(s)\,\frac{d}{ds}U(s)\,G(s_0)^\dagger = \Big(\partial_s G(s) - G(s)A_\gamma(s)\Big)\,U(s)\,G(s_0)^\dagger.$$

Using $(\star)$ and $\widetilde{U}(s) = G(s)U(s)G(s_0)^\dagger$ we compute

$$-\,A'_\gamma(s)\,\widetilde{U}(s) = -\Big(GA_\gamma G^\dagger - \partial_s G\,G^\dagger\Big)\,GUG(s_0)^\dagger = \Big(\partial_s G - GA_\gamma\Big)\,U\,G(s_0)^\dagger = \frac{d}{ds}\widetilde{U}(s).$$

Thus $\widetilde{U}$ solves the gauge–transformed ODE $\frac{d}{ds}\widetilde{U}(s) = -A'_\gamma(s)\widetilde{U}(s)$ with $\widetilde{U}(s_0) = \mathbf{1}$. By uniqueness of solutions of eq. (4.12),

$$\mathcal{U}'(x \leftarrow x';\gamma) = \widetilde{U}(s_1) = G(s_1)\,U(s_1)\,G(s_0)^\dagger = g(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,g(x')^\dagger,$$

which is the desired covariance law.

Equivalently, in the path-ordered exponential form eq. (4.11) and using reparametrization invariance Lemma 4.50,

$$\mathcal{P}\exp\Big(-\int A'_\gamma\Big) = \mathcal{P}\exp\Big(-\int\Big(GA_\gamma G^\dagger - \partial_s G\,G^\dagger\Big)\,ds\Big) = G(s_1)\,\Big(\mathcal{P}\exp\Big(-\int A_\gamma\,ds\Big)\Big)\,G(s_0)^\dagger,$$

the last equality being the standard gauge–cocycle identity for ordered exponentials. This coincides with the ODE proof.

Finally, combining this with the selector transformation $\hat{\mathcal{F}}_\alpha(y) \mapsto g(y)\hat{\mathcal{F}}_\alpha(y)$, one immediately obtains the channel and Fourfold kernel covariance $\hat{G}^{\alpha\beta}_\Lambda(x,x') \mapsto g(x)\hat{G}^{\alpha\beta}_\Lambda(x,x')g(x')^\dagger$, in agreement with Corollary 4.64 and Proposition 4.14. □

Remark 4.55 (Meaning of Proposition 4.54)**.** The statement eq. (4.16) expresses how a change of local frame $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ affects both the connection one–form and the induced parallel transport of Definitions 4.48 and 4.49.

(i) Change of trivialization (connection level). The transformed connection $\mathcal{A}' = g\,\mathcal{A}\,g^\dagger + g\,\mathrm{d}g^\dagger$ contains an *adjoint* term (rotation of components) and an *inhomogeneous* term (the Maurer–Cartan 1-form $g\,\mathrm{d}g^\dagger$) that compensates the change of frame. This is the standard frame-change law for a unitary connection and ensures that the covariant derivative transforms tensorially.

(ii) Endpoint conjugation (transport level). For any path $\gamma : x' \to x$, the transporter transforms by endpoint conjugation,

$$\mathcal{U}'(x \leftarrow x'; \gamma) = g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^\dagger, \qquad \text{(eq. (4.16))}.$$

Thus $\mathcal{U}$ is not gauge *invariant* but gauge *covariant* as a morphism $\mathcal{H}_{\mathrm{em}}(x') \to \mathcal{H}_{\mathrm{em}}(x)$: changing frames applies the corresponding endpoint changes to source/target fibres.

(iii) Compatibility with functoriality and reparametrization. Since endpoint conjugation distributes over products and inverses, the gauge law is compatible with composition and path reversal in Proposition 4.52 and eqs. (4.14) and (4.15), and with unitarity/reparametrization invariance in Lemma 4.50. In categorical terms, g defines a natural isomorphism between the functors $\gamma \mapsto \mathcal{U}$ and $\gamma \mapsto \mathcal{U}'$ from the path groupoid of $\mathcal{X}_q$ to $\mathrm{U}(\mathcal{H}_{\mathrm{em}})$.

(iv) Curvature and holonomy. At the 2-form level, curvature transforms adjointly, $\mathcal{F}' = g\,\mathcal{F}\,g^\dagger$ (Corollary 4.57), so the Bianchi identity and flatness are gauge invariant. For loops ℓ based at x, holonomy obeys $\mathrm{Hol}'_\ell(x) = g(x)\,\mathrm{Hol}_\ell(x)\,g(x)^\dagger$ (Definition 4.56), hence its conjugacy class (e.g. trace/Wilson loop) is gauge invariant.

(v) Flat connections as pure gauges. On simply connected regions with $\mathcal{F} = 0$ one can choose g so that $\mathcal{A}' = 0$. Then transports are identity in that gauge, and in any gauge they reduce to the pure endpoint form $\mathcal{U}(x \leftarrow x'; \gamma) = g(x)\,g(x')^\dagger$, i.e. path independence (Proposition 4.59).

(vi) Channels and observable covariance. With selectors transforming as $\hat{\mathcal{F}}_\alpha(y) \mapsto g(y)\hat{\mathcal{F}}_\alpha(y)$ (Chapter 1), the Fourfold channel $\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x')$ transforms covariantly, $\hat{G}_\Lambda^{\alpha\beta} \mapsto g(x)\hat{G}_\Lambda^{\alpha\beta}g(x')^\dagger$ (Definition 4.61 and Corollary 4.64). Consequently, scalar Born quantities built by sandwiching with physical states are gauge invariant, and Hermitian symmetry $(\hat{G}_\Lambda^{\alpha\beta})^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x)$ remains compatible with covariance (Lemma 4.66).

In short, Proposition 4.54 formalizes gauge as a change of local frame: the connection picks up the expected inhomogeneous term, while parallel transport and all objects built from it transform by endpoint conjugation—preserving the gauge invariants that drive the theory upstream and across Chapters 1–3.

Definition 4.56 (Curvature and holonomy of the unitary connection)**.** Let $\mathcal{A} \in \Omega^1\big(\mathcal{X}_q,\ \mathfrak{u}(\mathcal{H}_{\mathrm{em}})\big)$ be the (skew-Hermitian) unitary connection one-form underlying the parallel transport of Definitions 4.48 and 4.49. The *curvature* two-form is

$$\mathcal{F} \;:=\; \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A} \;\in\; \Omega^2\big(\mathcal{X}_q,\ \mathfrak{u}(\mathcal{H}_{\mathrm{em}})\big), \tag{4.17}$$

which satisfies the (nonabelian) *Bianchi identity* $\mathrm{d}\mathcal{F} + \mathcal{A}\wedge\mathcal{F} - \mathcal{F}\wedge\mathcal{A} = 0$. For any piecewise C^1 loop ℓ based at $x \in \mathcal{X}_q$, the *holonomy* is

$$\mathrm{Hol}_\ell(x) = \mathcal{U}(x \leftarrow x; \ell) = \mathcal{P}\,\exp\!\Big(-\oint_\ell \mathcal{A}\Big) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}}). \tag{4.18}$$

(Flatness implies path-independence on simply connected regions; see Proposition 4.59. Gauge covariance of $\mathcal{F}$ is given in Corollary 4.57.)

Corollary 4.57 (Curvature covariance)**.** *Under the gauge change $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ with $\mathcal{A}' = g\,\mathcal{A}\,g^\dagger + g\,\mathrm{d}g^\dagger$ (cf. eq. (4.16)), the curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$ (cf. Definition 4.56) transforms covariantly:*

$$\mathcal{F}' \;:=\; \mathrm{d}\mathcal{A}' + \mathcal{A}'\wedge\mathcal{A}' \;=\; g\,\mathcal{F}\,g^\dagger.$$

In particular, the Bianchi identity and flatness are gauge invariant.

Proof. Write the *gauge–covariant exterior derivative* associated with a connection $\mathcal{A}$ as $D_{\mathcal{A}}X := \mathrm{d}X + \mathcal{A}\wedge X - X\wedge\mathcal{A}$ for any Lie–algebra valued form X. Then $\mathcal{F} = D_{\mathcal{A}}\mathcal{A} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$ (cf. Definition 4.56). We show the natural covariance

$$D_{\mathcal{A}'}(g\,X\,g^\dagger) \;=\; g\,D_{\mathcal{A}}X\,g^\dagger, \tag{4.19}$$

from which the claimed law follows by setting $X = \mathcal{A}$: $\mathcal{F}' = D_{\mathcal{A}'}\mathcal{A}' = D_{\mathcal{A}'}(g\mathcal{A}g^\dagger + g\,\mathrm{d}g^\dagger) = D_{\mathcal{A}'}(g\mathcal{A}g^\dagger) = g\,D_{\mathcal{A}}\mathcal{A}\,g^\dagger = g\,\mathcal{F}\,g^\dagger$.

To prove (4.19), expand using $\mathcal{A}' = g\mathcal{A}g^\dagger + g\,\mathrm{d}g^\dagger$ (eq. (4.16)), $g^\dagger g = \mathbf{1}$, and $\mathrm{d}(g^\dagger g) = 0 \Rightarrow \mathrm{d}g^\dagger\,g = -g^\dagger\mathrm{d}g$:

$$\begin{aligned} D_{\mathcal{A}'}(gXg^\dagger) &= \mathrm{d}(gXg^\dagger) + \mathcal{A}'\wedge(gXg^\dagger) - (gXg^\dagger)\wedge\mathcal{A}' \\ &= (\mathrm{d}g)\wedge Xg^\dagger + g\,\mathrm{d}X\,g^\dagger + gX\wedge\mathrm{d}g^\dagger \\ &\quad + (g\mathcal{A}g^\dagger)\wedge(gXg^\dagger) + (g\,\mathrm{d}g^\dagger)\wedge(gXg^\dagger) - (gXg^\dagger)\wedge(g\mathcal{A}g^\dagger) - (gXg^\dagger)\wedge(g\,\mathrm{d}g^\dagger). \end{aligned}$$

Because g and $g^\dagger$ are 0-forms, we may pull them through wedge products, preserving order. Using $\mathrm{d}g^\dagger = -g^\dagger\mathrm{d}g\,g^\dagger$ and $(g\,\mathrm{d}g^\dagger) = -(\mathrm{d}g)\,g^\dagger$, the terms involving $\mathrm{d}g$ cancel pairwise, leaving

$$D_{\mathcal{A}'}(gXg^\dagger) = g\Big(\mathrm{d}X + \mathcal{A}\wedge X - X\wedge\mathcal{A}\Big)g^\dagger = g\,D_{\mathcal{A}}X\,g^\dagger,$$

which establishes (4.19). Taking $X = \mathcal{A}$ gives $\mathcal{F}' = g\,\mathcal{F}\,g^\dagger$.

For the Bianchi identity, $D_{\mathcal{A}}\mathcal{F} = 0$ (stated with Definition 4.56) implies $D_{\mathcal{A}'}\mathcal{F}' = D_{\mathcal{A}'}(g\mathcal{F}g^\dagger) = g\,D_{\mathcal{A}}\mathcal{F}\,g^\dagger = 0$ by (4.19). In particular, $\mathcal{F} = 0$ (flatness) $\Rightarrow \mathcal{F}' = g\,0\,g^\dagger = 0$, so both the Bianchi identity and flatness are gauge invariant. □

Remark 4.58 (Meaning of Corollary 4.57)**.** The corollary states that while the connection $\mathcal{A}$ transforms *affinely* (a rotated part plus an inhomogeneous Maurer–Cartan term), its curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$ transforms *tensorially* (pure adjoint action):

$$\begin{aligned} &\mathcal{A}' = g\mathcal{A}g^\dagger + g\,\mathrm{d}g^\dagger \quad \text{but} \\ &\mathcal{F}' = g\,\mathcal{F}\,g^\dagger \qquad \text{(Proposition 4.54 and eq. (4.16) and Corollary 4.57).} \end{aligned} \tag{4.20}$$

Hence $\mathcal{F}$ is the intrinsic "field strength'' of the connection: a change of local frame does not create or destroy curvature; it only conjugates it pointwise in the fibre.

(i) Covariant differentiation and Bianchi. The identity $D_{\mathcal{A}'}(gXg^\dagger) = g\, D_{\mathcal{A}} X\, g^\dagger$ (eq. (4.19)) shows that the covariant exterior derivative respects gauge change. Setting $X = \mathcal{A}$ yields curvature covariance, and with $D_{\mathcal{A}}\mathcal{F} = 0$ (Bianchi; Definition 4.56) one obtains $D_{\mathcal{A}'}\mathcal{F}' = 0$. Thus both Bianchi identity and the condition $\mathcal{F} = 0$ (flatness) are gauge invariant.

(ii) Holonomy and local loop control. Holonomy along a loop ℓ based at x, $\mathrm{Hol}_\ell(x) = \mathcal{U}(x \leftarrow x; \ell)$ (Definition 4.56 and eq. (4.18)), transforms by endpoint conjugation: $\mathrm{Hol}'_\ell(x) = g(x)\,\mathrm{Hol}_\ell(x)\,g(x)^\dagger$ (Proposition 4.54). Curvature covariance is the infinitesimal counterpart of this statement: $\mathcal{F}$ governs holonomy around small loops, and its adjoint transformation mirrors the holonomy conjugation. Consequently, conjugacy-class quantities (e.g. Wilson loops, cyclic traces where defined) are gauge invariant.

(iii) Flat connections and pure gauges. On simply connected regions, $\mathcal{F} = 0$ implies there exists g with $\mathcal{A}' = 0$; then transports are identity in that gauge and, in any gauge, $\mathcal{U}(x \leftarrow x'; \gamma) = g(x)\, g(x')^\dagger$ (path independence) (Proposition 4.59). Curvature covariance guarantees this characterisation is frame-stable.

(iv) Building gauge invariants from curvature. Because $\mathcal{F}$ transforms adjointly, any Ad-invariant functional of $\mathcal{F}$ (e.g. class functions, cyclic traces of polynomials in $\mathcal{F}$ when defined) is gauge invariant. This is the curvature-level analogue of endpoint-conjugation invariance for holonomy-based observables.

(v) Compatibility with transport-level covariance. The transporter obeys $\mathcal{U} \mapsto g(x)\,\mathcal{U}\,g(x')^\dagger$ (Proposition 4.54 and eq. (4.16)); curvature obeys $\mathcal{F} \mapsto g\,\mathcal{F}\,g^\dagger$ (Corollary 4.57). These two laws are compatible through the nonabelian Stokes viewpoint linking small-loop holonomy to $\mathcal{F}$, and together ensure that all higher constructions (holonomy classes, channel and correlator objects assembled via transports) have the expected gauge behaviour upstream in Chapter 4 and across Chapters 1–3.

Proposition 4.59 (Flatness ⇒ path independence)**.** *If $\mathcal{F} = 0$ on a simply connected neighbourhood of x, then $\mathcal{U}(x \leftarrow x'; \gamma)$ depends only on the endpoints x', x (i.e. is path independent and reduces to a gauge choice. Equivalently, all holonomies $\mathrm{Hol}_\ell(x)$ are the identity there.*

Proof of Proposition 4.59. Step 0 (Setup). Fix a simply connected open set $U \subset \mathcal{X}_q$ containing x and any x' under consideration. Parallel transport along a piecewise C^1 path $\gamma : x' \to x$ is the ordered exponential $\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{P}\exp\!\left(-\int_\gamma \mathcal{A}\right)$ by Definition 4.48 and eq. (4.11), with composition/inversion as in Proposition 4.52 and eqs. (4.14) and (4.15). The curvature and holonomy are defined in Definition 4.56 and eqs. (4.17) and (4.18). Flatness is gauge-invariant by Corollary 4.57.

Step 1 (Zero curvature ⇒ trivial holonomy). Let ℓ be any (piecewise C^1) loop in U based at x. Choose a smooth spanning surface $S \subset U$ with $\partial S = \ell$ (which exists because U is simply connected). The nonabelian Stokes argument applied to $\mathcal{F} = 0$ yields $\mathrm{Hol}_\ell(x) = \mathcal{P}\exp\!\left(-\oint_\ell \mathcal{A}\right) = \mathbf{1}$ (see Definition 4.56 for Hol_ℓ). Hence every contractible loop has identity holonomy.

Step 2 (Trivial holonomy ⇒ path independence). Take two paths $\gamma_1, \gamma_2 : x' \to x$ in U. The concatenation $\ell := \gamma_1 \circ \gamma_2^{-1}$ is a loop at x. By Step 1, $\mathrm{Hol}_\ell(x) = \mathbf{1}$. Using functoriality eqs. (4.14) and (4.15),

$$\mathbf{1} = \mathcal{U}(x \leftarrow x; \ell) = \mathcal{U}(x \leftarrow x'; \gamma_1)\,\mathcal{U}(x' \leftarrow x; \gamma_2^{-1}) = \mathcal{U}(x \leftarrow x'; \gamma_1)\,\Big(\mathcal{U}(x \leftarrow x'; \gamma_2)\Big)^{-1},$$

so $\mathcal{U}(x \leftarrow x'; \gamma_1) = \mathcal{U}(x \leftarrow x'; \gamma_2)$. Thus the transporter depends only on the endpoints.

Step 3 (Path independence ⇒ pure gauge; explicit gauge form). Fix a basepoint $x_0 \in U$. Define $g : U \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ by

$$g(y) := \mathcal{U}\Big(y \leftarrow x_0; \gamma_{x_0 \to y}\Big),$$

where $\gamma_{x_0 \to y}$ is any path in U from x_0 to y. By Step 2 this is well-defined (independent of the path). Let γ be any curve with $\gamma(0) = y$. Along γ, the ODE characterisation Definition 4.49 and eq. (4.12) gives $\partial_s g(\gamma(s)) = -A_\gamma(s)\, g(\gamma(s))$. Multiplying on the right by $g(\gamma(s))^\dagger$ and recalling that $(\gamma^*\mathcal{A})_s(\dot\gamma) = A_\gamma(s)$ (eq. (4.10)) yields the pointwise identity

$$(\gamma^*\mathcal{A})_s(\dot\gamma) = -\,\partial_s g(\gamma(s))\, g(\gamma(s))^\dagger \quad \Longleftrightarrow \quad \mathcal{A} \;=\; -\,(\mathrm{d}g)\, g^\dagger \;\text{ on } U.$$

Equivalently, with the gauge $h := g^\dagger$ the transformed connection is $\mathcal{A}^h = h\,\mathcal{A}\,h^\dagger + h\,\mathrm{d}h^\dagger = 0$ by Proposition 4.54 and eq. (4.16).

Step 4 (Reduction to a gauge choice). In the gauge $\mathcal{A}^h = 0$, the transporter is the identity along every path by eq. (4.12). Transforming back (again Proposition 4.54 and eq. (4.16)),

$$\mathcal{U}(x \leftarrow x'; \gamma) = g(x)\,\mathbf{1}\,g(x')^\dagger = g(x)\,g(x')^\dagger,$$

which depends only on the endpoints and is a pure gauge. This proves the first claim.

Equivalence with holonomy triviality. Setting $x' = x$ and $\gamma = \ell$ a loop based at x gives $\mathrm{Hol}_\ell(x) = \mathcal{U}(x \leftarrow x; \ell) = g(x)g(x)^\dagger = \mathbf{1}$ (cf. eq. (4.18)), so the holonomy statement is equivalent to path independence on simply connected U.

Cross-chapter corollaries. (i) For the Fourfold channel operator $\hat G_\Lambda^{\alpha\beta}(x, x')$ (Definition 4.61), flatness on U gives the path-independent form

$$\hat G_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\, g(x)\, g(x')^\dagger\, \hat{\mathcal{F}}_\beta(x'),$$

consistent with gauge covariance (Corollary 4.64). The full correlator block hence depends only on endpoints, not on the chosen γ.

(ii) In the parasymmetric sector of Chapter 2, invariants defined by projectors/evolutions remain well-defined under the endpoint-only transporter (no path ambiguity), matching the invariance statements surrounding parasymmetry-preserving dynamics (see Chapter 2, esp. the unitary invariance property referenced as *eq.* (2.60)).

(iii) In the holosymmetric interferometer of Chapter 3, the normal form $\mathbf{U}_{\mathrm{holo}} = (\mathbf{U}_{\mathrm{read}} \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(\mathbf{U}_{\mathrm{prep}} \otimes I)$ (eq. (3.35)) and the holosymmetric effect $E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ (eq. (3.36)) simplify when the register-wide evolutions differ only by flat, endpoint-only transports: the "dissonance" channel measured by lensing in Chapter 3 vanishes in this regime, so the control readout becomes gauge-equivalent across branches. □

Remark 4.60 (Meaning of Proposition 4.59)**.** The proposition states that *vanishing curvature on a simply connected region* turns parallel transport into a purely endpoint object—no memory of the path remains. This is the local *integrability* of the connection: there exists a gauge in which the connection one–form vanishes and transports are identities.

(i) Flat ⇒ pure gauge. If $\mathcal{F} = 0$ on U, there is a frame $g : U \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ with $\mathcal{A}' = g\mathcal{A}g^\dagger + g\,\mathrm{d}g^\dagger = 0$ (Proposition 4.54 and eq. (4.16)). In that frame, the ODE of transport (Definition 4.49 and eq. (4.12)) yields $\mathcal{U}'(x \leftarrow x'; \gamma) = \mathbf{1}$ for all paths γ, so in any frame

$$\mathcal{U}(x \leftarrow x'; \gamma) = g(x)\, g(x')^\dagger,$$

i.e. a *pure gauge* depending only on endpoints (no path data).

(ii) Holonomy triviality as the loop version. Holonomy $\mathrm{Hol}_\ell(x) = \mathcal{U}(x \leftarrow x; \ell)$ (Definition 4.56 and eq. (4.18)) becomes the identity for every contractible loop in a simply connected region. This is the infinitesimal/nonabelian Stokes manifestation of $\mathcal{F} = 0$: curvature covariance $\mathcal{F}' = g\mathcal{F}g^\dagger$ (Corollary 4.57) shows flatness is gauge invariant, hence so is holonomy triviality.

(iii) Path groupoid collapse. Functoriality of transport (Proposition 4.52 and eqs. (4.14) and (4.15)) and reparametrization invariance (Lemma 4.50) together imply that, under flatness, the path groupoid over U collapses to the discrete groupoid of *points only*: morphisms are uniquely determined by their endpoints. Concatenations and reversals reduce to multiplication and inversion of endpoint factors $g(x)$.

(iv) Topological caveat (global vs. local). The simply connected hypothesis is essential. If U is not simply connected, $\mathcal{F} = 0$ still enforces *local* path independence, but nontrivial global holonomy may survive around noncontractible loops (flat connections with nontrivial monodromy). Thus the result is best viewed as "flat + no topological obstruction ⇒ pure gauge."

(v) Consequences for channels and observables. For the Fourfold channel $\hat{G}^{\alpha\beta}_\Lambda(x, x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$ (Definition 4.61), flatness gives the endpoint-only form

$$\hat{G}^{\alpha\beta}_\Lambda(x, x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\, g(x)\, g(x')^\dagger\, \hat{\mathcal{F}}_\beta(x'),$$

which is manifestly compatible with channel covariance (Corollary 4.64) and Hermitian symmetry (Lemma 4.66). Born quantities built from these channels then become independent of the choice of path γ.

In short, Proposition 4.59 identifies $\mathcal{F}$ as the sole local obstruction to path-dependent transport: when $\mathcal{F} = 0$ and the topology is simple, the connection is gauge-equivalent to zero and all transports/holonomies reduce to endpoint data.

Definition 4.61 (Frame-consistent comparison and Fourfold channel)**.** To compare modal data between distinct loci $x', x \in \mathcal{X}_q$ in a frame–consistent way, use the *gauge–covariant parallel transporter* $\mathcal{U}(x \leftarrow x'; \gamma) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, i.e. the unitary defined along a piecewise C^1 path $\gamma : x' \to x$ by the path–ordered exponential in Definition 4.48. Given Fourfold selectors $\hat{\mathcal{F}}_\alpha$ (Chapter 1; $\alpha \in \{0, 1, p, s\}$), the *single channel* of the Fourfold correlator from mode β at x' to mode α at x is the composite operator

$$\hat{G}^{\alpha\beta}_\Lambda(x, x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x'). \tag{4.21}$$

The transporter satisfies the standard covariant properties (see Propositions 4.52 and 4.54 and Lemma 4.50):

Composition: $\mathcal{U}(x \leftarrow x''; \gamma_1)\,\mathcal{U}(x'' \leftarrow x'; \gamma_2) = \mathcal{U}(x \leftarrow x'; \gamma_1 \circ \gamma_2)$,

Unitarity / reversal: $\mathcal{U}(x \leftarrow x'; \gamma)^\dagger = \mathcal{U}(x' \leftarrow x; \gamma^{-1}), \qquad \|\mathcal{U}\| = 1,$

Gauge covariance: $\hat{\mathcal{F}}_\alpha(y) \mapsto g(y)\hat{\mathcal{F}}_\alpha(y), \qquad \mathcal{U}(x \leftarrow x'; \gamma) \mapsto g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^\dagger,$

and therefore each channel transforms covariantly (cf. Corollary 4.64):

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') \;\longmapsto\; g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x, x')\,g(x')^\dagger.$$

Remark 4.62 (Gauge transformation, reparametrization, composition and inversion — collected laws)**.** Under a local gauge g, recall eq. (4.16). The transporter is invariant under monotone C^1 reparametrizations (Lemma 4.50) and satisfies eqs. (4.14) and (4.15).

Definition 4.63 (Gauge–covariant parallel transport between PQS loci (restatement))**.** This is exactly the parallel transporter of Definitions 4.48 and 4.49; no new content is introduced here.

Corollary 4.64 (Covariance of the channel operator)**.** *Under the gauge action of Proposition 4.54 and the selector law $\hat{\mathcal{F}}_\alpha(y) \mapsto g(y)\hat{\mathcal{F}}_\alpha(y)$,*

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') \;\mapsto\; g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x, x')\,g(x')^\dagger.$$

Proof of Corollary 4.64. Step 0 (Definitions and types). By Definition 4.61, the (α, β)-channel is

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x'),$$

where $\mathcal{U}$ is the parallel transporter of Definitions 4.48 and 4.49 and satisfies the gauge law of Proposition 4.54 and eq. (4.16): $\mathcal{U} \mapsto g(x)\,\mathcal{U}\,g(x')^\dagger$.

Step 1 (Selector conventions and induced adjoint action). Chapter 1 treats the Fourfold selectors as fibre-valued sections; at each locus y, the "ket–side" selector $\hat{\mathcal{F}}_\beta(y)$ transforms by left multiplication, $\hat{\mathcal{F}}_\beta(y) \mapsto g(y)\hat{\mathcal{F}}_\beta(y)$. This induces the *contragredient* action on the adjoint

$$\hat{\mathcal{F}}_\alpha^\dagger(y) \;\mapsto\; \hat{\mathcal{F}}_\alpha^\dagger(y)\,g(y)^\dagger.$$

Equivalently—viewing $\hat{\mathcal{F}}_\alpha^\dagger(y)$ as an intertwiner $\mathcal{H}_{\mathrm{em}}(y) \to \mathbb{C}$ while $\hat{\mathcal{F}}_\beta(y)$ as $\mathbb{C} \to \mathcal{H}_{\mathrm{em}}(y)$—the gauge acts on the fibre factor only.

Step 2 (Endpoint-wise transformation). Apply Proposition 4.54 and eq. (4.16) to the transporter and the selector rules of Step 1:

$$\begin{aligned}
\hat{G}_\Lambda^{\alpha\beta}(x, x') \;&\mapsto\; \big(\hat{\mathcal{F}}_\alpha^\dagger(x)\,g(x)^\dagger\big)\,\big(g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^\dagger\big)\,\big(g(x')\,\hat{\mathcal{F}}_\beta(x')\big) \\
&=\; \hat{\mathcal{F}}_\alpha^\dagger(x)\,\big[g(x)^\dagger g(x)\big]\,\mathcal{U}(x \leftarrow x'; \gamma)\,\big[g(x')^\dagger g(x')\big]\,\hat{\mathcal{F}}_\beta(x') \\
&=\; \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x') \\
&=\; \hat{G}_\Lambda^{\alpha\beta}(x, x').
\end{aligned}$$

This shows that, *as a scalar-valued intertwiner* $\mathbb{C} \to \mathbb{C}$ (obtained by composing the fibre maps with the selectors), the channel is gauge invariant.

If instead we regard the *pure transport operator* between fibres, namely $\mathsf{G}(x, x') := \mathcal{U}(x \leftarrow x'; \gamma) \in \mathrm{Hom}\big(\mathcal{H}_{\mathrm{em}}(x'), \mathcal{H}_{\mathrm{em}}(x)\big)$, then by Proposition 4.54 it transforms *covariantly*: $\mathsf{G}(x, x') \mapsto g(x)\, \mathsf{G}(x, x')\, g(x')^\dagger$. Inserting *gauge-neutral* intertwiners (fixing the selector frames as in Definition 4.61) recovers the endpoint conjugation rule for each operator-valued block:

$$\boxed{\hat{G}^{\alpha\beta}_\Lambda(x, x') \;\mapsto\; g(x)\, \hat{G}^{\alpha\beta}_\Lambda(x, x')\, g(x')^\dagger}$$

which is the stated covariance.

Step 3 (Block assembly and consistency). Assembling the blocks into $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}^{\alpha\beta}_\Lambda(x, x')]_{\alpha,\beta}$ (Remark 4.67 and Definition 4.9), the same computation yields $\hat{\mathbf{G}}_\Lambda(x, x') \mapsto g(x)\, \hat{\mathbf{G}}_\Lambda(x, x')\, g(x')^\dagger$, consistent with Fourfold gauge covariance (Proposition 4.14) and Hermitian symmetry (Lemma 4.66).

Cross-chapter links. (i) **Chapter 1 (selectors).** The transformation in Step 1 is the fibre action on mode-selecting sections; the endpoint conjugation claimed here is precisely the induced action on the assembled channel.

(ii) **Chapter 2 (Twofold slice).** Restricting to $\alpha, \beta \in \{0, 1\}$ recovers the Twofold kernel transform and its invariance of Born expectations, matching the Twofold properties (cf. *Proposition* 4.4 in the Twofold setting).

(iii) **Chapter 3 (holosymmetric effects).** Because holosymmetric effects are obtained by sandwiching the transport with control preparation/readout and taking Born values (eqs. (3.35) and (3.36)), their numerical predictions are gauge invariant even as the intermediate channel transforms covariantly as above.

This completes the proof. □

Remark 4.65 (Meaning of Corollary 4.64)**.** The corollary states that Fourfold channels transform by *endpoint conjugation* under a local gauge $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$:

$$\hat{G}^{\alpha\beta}_\Lambda(x, x') \;\longmapsto\; g(x)\, \hat{G}^{\alpha\beta}_\Lambda(x, x')\, g(x')^\dagger,$$

where $\hat{G}^{\alpha\beta}_\Lambda(x, x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$ (Definition 4.61) and $\mathcal{U}$ obeys the transport gauge law (Proposition 4.54 and eq. (4.16)). This captures the idea that a gauge change is a *change of frames* at the source and target fibres, so the channel—viewed as a morphism $\mathcal{H}_{\mathrm{em}}(x') \to \mathcal{H}_{\mathrm{em}}(x)$—is not invariant but *covariant*.

(i) Operator vs. scalar viewpoints. If one fixes selector frames (treating $\hat{\mathcal{F}}^\dagger_\alpha(x)$ and $\hat{\mathcal{F}}_\beta(x')$ as gauge-neutral intertwiners in the sense of Definition 4.61), the assembled operator block transforms by endpoint conjugation, as stated. If instead the selectors are allowed to co-transform with the fibre $\hat{\mathcal{F}}_\beta(y) \mapsto g(y)\hat{\mathcal{F}}_\beta(y)$ (and hence $\hat{\mathcal{F}}^\dagger_\alpha(y) \mapsto \hat{\mathcal{F}}^\dagger_\alpha(y)g(y)^\dagger$; cf. the proof), then all gauge factors cancel and the *scalar* obtained by full contraction is gauge invariant.

(ii) Block and matrix levels. Endpoint conjugation acts entrywise on the 4×4 Fourfold kernel $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}^{\alpha\beta}_\Lambda(x, x')]_{\alpha,\beta}$, hence $\hat{\mathbf{G}}_\Lambda(x, x') \mapsto g(x)\, \hat{\mathbf{G}}_\Lambda(x, x')\, g(x')^\dagger$, consistent with global Fourfold covariance (Proposition 4.14). This behaviour commutes with Hermitian symmetry $(\hat{G}^{\alpha\beta}_\Lambda)^\dagger = \hat{G}^{\beta\alpha}_\Lambda(x', x)$ (Lemma 4.66) because adjoint simultaneously swaps endpoints and applies the inverse conjugations.

(iii) Observables and Born values. Physical predictions are formed by sandwiching channels with preparation/readout maps or states; such Born quantities are invariant under $X \mapsto g(x)Xg(x')^\dagger$ because the gauge action is a change of basis on the boundary fibres. Thus covariance at the operator level implies invariance at the scalar (observable) level.

(iv) Compatibility with path structure and curvature. Covariance is compatible with composition/inversion of transports (Proposition 4.52) since endpoint conjugation distributes over products and inverses. In the flat, simply connected regime (Proposition 4.59), $\mathcal{U}(x \leftarrow x';\gamma) = g(x)g(x')^\dagger$, so the channel becomes an explicit pure endpoint conjugation of the selectors, matching the statement here.

(v) Twofold and cross-chapter consistency. Restricting $\alpha, \beta \in \{0, 1\}$ recovers the Twofold covariance used in Chapter 2; in Chapter 3, holosymmetric effects built from these channels (via the normal form and Born evaluation) inherit gauge invariance of their numerical predictions while the intermediate channels transform covariantly as above.

In short, Corollary 4.64 formalizes that channels are well-defined geometric intertwiners between fibres: they transport modal data in a way that respects frame changes at the endpoints, while leaving experimentally meaningful scalars unchanged.

Lemma 4.66 (Hermitian symmetry of channels)**.** *For all $\alpha, \beta \in \{0, 1, p, s\}$,*

$$\left(\hat{G}_\Lambda^{\alpha\beta}(x, x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x),$$

hence the block matrix $\hat{\mathbf{G}}_\Lambda(x, x')$ obeys $\hat{\mathbf{G}}_\Lambda(x, x')^\dagger = \hat{\mathbf{G}}_\Lambda(x', x)$.

Proof of Lemma 4.66. Step 0 (Channel and transport). By Definition 4.61, the (α, β)-channel is

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') \;=\; \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x';\gamma)\, \hat{\mathcal{F}}_\beta(x'),$$

with $\mathcal{U}$ the parallel transporter of Definitions 4.48 and 4.49. Unitarity and path reversal give

$$\mathcal{U}(x \leftarrow x';\gamma)^\dagger = \mathcal{U}(x' \leftarrow x;\gamma^{-1}) \qquad \text{(Lemma 4.50, Proposition 4.52, and eq. (4.15)).}$$

Step 1 (Take adjoint). Compute the adjoint using $(ABC)^\dagger = C^\dagger B^\dagger A^\dagger$ and the above identity:

$$\left(\hat{G}_\Lambda^{\alpha\beta}(x, x')\right)^\dagger = \hat{\mathcal{F}}_\beta^\dagger(x')\, \mathcal{U}(x' \leftarrow x;\gamma^{-1})\, \hat{\mathcal{F}}_\alpha(x).$$

Step 2 (Recognise the swapped channel). By Definition 4.61 evaluated at (x', x) with modes (β, α),

$$\hat{G}_\Lambda^{\beta\alpha}(x', x) = \hat{\mathcal{F}}_\beta^\dagger(x')\, \mathcal{U}(x' \leftarrow x;\gamma^{-1})\, \hat{\mathcal{F}}_\alpha(x).$$

Comparing with Step 1 yields $\left(\hat{G}_\Lambda^{\alpha\beta}(x, x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x)$.

Step 3 (Block Hermiticity). Assembling $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}_\Lambda^{\alpha\beta}(x, x')]_{\alpha,\beta}$ and applying the entrywise identity gives $\hat{\mathbf{G}}_\Lambda(x, x')^\dagger = \hat{\mathbf{G}}_\Lambda(x', x)$.

Alternative view (ordered exponentials). From Definition 4.48 and eq. (4.11) and the standard reverse-ordering rule $\left(\mathcal{P}e^{\int M}\right)^\dagger = \widetilde{\mathcal{P}}\, e^{\int M^\dagger}$, unitarity of the generator $A_\gamma^\dagger = -A_\gamma$ implies directly $\mathcal{U}(x \leftarrow x';\gamma)^\dagger = \mathcal{U}(x' \leftarrow x;\gamma^{-1})$, which feeds into Steps 1–2.

Consistency and cross-chapter links. (i) **Twofold slice (Chapter 2).** Restricting $\alpha, \beta \in \{0, 1\}$ recovers the Twofold Hermitian symmetry (Proposition 4.3). (ii) **Holosymmetric effects (Chapter 3).** Since holosymmetric readouts evaluate Born expectations of operators assembled from these channels (eqs. (3.35) and (3.36)), the result ensures the expected reality/adjoint consistency of those effects. (iii) **Gauge behaviour (Chapter 4 upstream).** This symmetry is compatible with covariance in Corollary 4.64 because taking adjoints exchanges $(x, \alpha) \leftrightarrow (x', \beta)$ while conjugating by endpoint gauges $g(x), g(x')$.

This completes the proof. □

Remark 4.67 (Consistency with Fourfold correlator assembly)**.** The block kernel $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}_\Lambda^{\alpha\beta}(x, x')]_{\alpha,\beta\in\{0,1,p,s\}}$ assembled from Definition 4.61 is exactly the Fourfold correlator of Definition 4.9. Its restriction to the Twofold sector yields the $(0, 1)$-block $\hat{\mathbf{G}}_{(0,1)}(x, x')$ (cf. Proposition 4.7). Gauge covariance (Corollary 4.64) and Hermitian symmetry (Lemma 4.66) match the Fourfold properties (Propositions 4.13 and 4.14); boundedness estimates are as in Proposition 4.15 and, for the Twofold slice, Proposition 4.5.

Remark 4.68 (Convention, domain, and geometric meaning)**. Convention.** The skew–Hermitian convention for the connection and transporter used in eqs. (4.11) and (4.18) (as organized in Section 4.1.4) takes $A_\gamma(s) = (\gamma^*\mathcal{A})_s(\dot\gamma(s)) \in \mathfrak{u}(\mathcal{H}_{\mathrm{em}})$ so that $A_\gamma(s)^\dagger = -A_\gamma(s)$. If one prefers Hermitian generators, set $H_\gamma(s) := -i\, A_\gamma(s)$, under which the transport ODE eq. (4.12) becomes $\frac{d}{ds}\mathcal{U} = -i\, H_\gamma \mathcal{U}$. This is a notational change only; all structural results (unitarity, functoriality, gauge covariance, curvature/holonomy relations) remain valid verbatim.

Domain. All operators act on the spectrally regulated fibres $\operatorname{Ran} E^{(x)}([0, \lambda_{\mathrm{cutoff}}])$ from eq. (4.303). This ensures strong continuity and well-posedness of the transport along any C^1 curve, in line with standard bundle/connection theory [248, 372].

Geometric meaning. Equation eq. (4.11) realises parallel transport as the path-ordered exponential of the unitary connection on the bundle of modal fibres over $\mathcal{X}_q$. Flat connections yield path-independent transport (pure gauge; Proposition 4.59), whereas nonzero curvature produces holonomy (Definition 4.56). Incorporating $\mathcal{U}(x \leftarrow x'; \gamma)$ into the Fourfold channels (Definition 4.61) is therefore essential for frame-consistent inter-locus comparison: endpoint data are related by a gauge–covariant map, and the assembled correlator inherits the correct transformation/adjoint properties (Corollary 4.64, Lemma 4.66, and Remark 4.67). Absent this transporter, the correlator entries—and the emergent inner product they induce—would be frame-dependent and hence ill-posed.

Remark 4.69 (Operational reading, tetralemma structure, diagnostics, and classical slice)**. Operational reading and its logical content.** The Fourfold inter–modal correlator is an operator–valued, gauge–covariant two–point kernel with entries

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x') \quad (\alpha, \beta \in \{0, 1, p, s\}),$$

that assemble into a 4×4 block $\hat{\mathbf{G}}_\Lambda(x, x')$ (Definition 4.61). Each channel effects a three–step procedure: *imprint* mode β at x', *gauge–align* along γ via $\mathcal{U}$, then *read out* mode α at x. Diagonals $\hat{G}^{\alpha\alpha}$ encode *modal persistence*, while off–diagonals $\hat{G}^{\alpha\beta}$ $(\alpha \neq \beta)$ encode *modal transitions* (e.g. $0 \leftrightarrow p$, $1 \leftrightarrow s$). Keeping $\hat{G}_\Lambda^{\alpha\beta}$ operator–valued ensures that context—state,

locus, and gauge—enters only upon taking expectations; covariance $\hat{G}_\Lambda^{\alpha\beta} \mapsto g(x)\hat{G}_\Lambda^{\alpha\beta}g(x')^\dagger$ (Corollary 4.64) guarantees gauge–invariant Born values after contraction. In the limit $x' \to x$, Holo–State expectations (Chapter 3) yield Born–valued amplitudes that *generate the local inner product* (cf. eq. (4.6)); thus the kernel is *generative* of the emergent Hilbert geometry.

From tetralemma to transport. The correlator realises the four corners of the tetralemma as operational facets and furnishes the transport/coupling among them. The top–left 2×2 block captures Thesis/Antithesis (Symmetry/Antisymmetry), recovering the classical dyad and its ordinary interference. Channels to p (Parasymmetry/Synthesis) quantify coherence–sensitive composition beyond mixtures (cf. Definition 2.94); channels to s (Holosymmetry/Holothesis) register implementation–invariant structure by comparing whole mechanisms (cf. eq. (3.36)). In this way the correlator acts as a multiport interferometer for logical facets, routing/mixing/reading each facet in a frame–consistent manner, with cross–couplings made explicit and measurable.

Prismatic diagnostics and duality. Given a state ρ, expectations of the matrix entries become Born–valued *degrees of warrant* for each facet and their couplings, thereby implementing the "prism of interrogations." The Axiom of Duality appears as completeness on the Twofold sector ($P_T + P_A = P_{(0,1)}$), while parasymmetric and holosymmetric channels extend the diagnostic space to coherent coexistence and global invariance (cf. Chapters 2–3).

Classical slice as a limit. When interrogations commute or decoherence suppresses phase information, off–diagonal and higher–mode couplings carry no independent signal: the 4×4 kernel *collapses to the Twofold block*. Non–Contradiction and Excluded Middle then re–emerge on their proper domain. Where coherence and architectural structure matter, the full Fourfold kernel is indispensable: it quantifies how logical facets persist, convert, and entangle across loci and—via its expectations—carves the inner–product geometry on which those facets are defined. This behaviour is consistent with functoriality/adjoint relations of transport (Proposition 4.52 and Lemma 4.66) and with gauge covariance at the operator level (Corollary 4.64).

4.1.5 Tensor Notation for the Fourfold Inter-Modal Correlator

Definition 4.70 (Dialectic mode labels and realization map)**.** Fix the ordered set of dialectic *mode labels* $\mathcal{I} := \{0, 1, p, s\}$. For each locus x, the *realization map*

$$\mathcal{R}_x : \mathcal{I} \longrightarrow \mathbb{P}\Big(\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}\Big)$$

sends a label $\alpha \in \mathcal{I}$ to a ray $\mathcal{R}_x(\alpha)$ in the emergent modal fiber at x. After the inner product is defined (cf. eq. (4.6)), choose unit representatives to form the ordered local dialectic frame

$$\mathcal{B}_x := \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}, \qquad \mathcal{R}_x(\alpha) = [\,|\alpha\rangle_x\,], \quad \alpha \in \mathcal{I}.$$

Remark 4.71 (Non-superpositional status of p and s)**.** The vectors $|p\rangle_x$ and $|s\rangle_x$ are *not* defined as linear combinations of $|0\rangle_x, |1\rangle_x$. The equal-superposition state $|+\rangle_x := \frac{1}{\sqrt{2}}(|0\rangle_x + |1\rangle_x)$ belongs to the Twofold sector and induces the local parasymmetric *effect* $P_{\text{para}}^{(x)} = |+\rangle_x\langle+|$, but it is not identified with $|p\rangle_x$.

Definition 4.72 (Dialectically resolved channel components)**.** Given Fourfold selectors $\hat{\mathcal{F}}_\alpha$ (Chapter 1), the gauge–covariant transporter $\mathcal{U}(x \leftarrow x';\gamma)$ (Chapter 4; cf. Definitions 4.48 and 4.49), and a path $\gamma \subset \mathcal{X}_q$ from x' to x, the *dialectically resolved components* of the correlator are the operator-valued tensor entries

$$\hat{G}_\Lambda^{\alpha\beta}(x,x') := \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x') \;\in\; \mathcal{B}(\mathcal{H}_{\mathrm{em}}), \qquad \alpha,\beta \in \mathcal{I}, \tag{4.22}$$

where α,β index the dialectic modes at the endpoints.

Definition 4.73 (Tensor-assembled kernel in a local dialectic frame)**.** For states $|\psi_1\rangle_x = \sum_{\alpha\in\mathcal{I}} c_{1\alpha}\,|\alpha\rangle_x$ and $|\psi_2\rangle_{x'} = \sum_{\beta\in\mathcal{I}} c_{2\beta}\,|\beta\rangle_{x'}$, write $c^{(1)} := (c_{10}, c_{11}, c_{1p}, c_{1s})^\top$ and $c^{(2)} := (c_{20}, c_{21}, c_{2p}, c_{2s})^\top$. The *tensor-assembled* operator-valued kernel is

$$\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2] = \sum_{\alpha,\beta\in\mathcal{I}} c_{1\alpha}^*\,c_{2\beta}\,\hat{G}_\Lambda^{\alpha\beta}(x,x') = \left(c^{(1)}\right)^\dagger \hat{\mathbf{G}}_\Lambda(x,x')\,c^{(2)}, \tag{4.23}$$

with the 4×4 block $\hat{\mathbf{G}}_\Lambda(x,x') = [\hat{G}_\Lambda^{\alpha\beta}(x,x')]_{\alpha,\beta\in\mathcal{I}}$.

Lemma 4.74 (Sesquilinearity and frame dependence)**.** *Define*

$$\mathcal{G}_{x,x'} :\; \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \times \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})} \longrightarrow \mathcal{B}(\mathcal{H}_{\mathrm{em}}), \qquad (|\psi_1\rangle_x,\,|\psi_2\rangle_{x'}) \longmapsto \hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2].$$

Then $\mathcal{G}_{x,x'}$ is conjugate–linear in $|\psi_1\rangle_x$ and linear in $|\psi_2\rangle_{x'}$. If the local dialectic frames $\mathcal{B}_x,\mathcal{B}_{x'}$ are changed to $\widetilde{\mathcal{B}}_x,\widetilde{\mathcal{B}}_{x'}$ by fixed relabelings within $\mathcal{I}$, then the column coefficients and the $\mathcal{I}$–indexed block transform compatibly so that the contracted quantity in eq. (4.23) is unchanged. (Gauge changes act as in Corollary 4.64.)

Corollary 4.75 (Componentwise covariance and Hermitian symmetry)**.** *The entries in eq. (4.22) satisfy, for all $\alpha,\beta\in\mathcal{I}$,*

$$\hat{G}_\Lambda^{\alpha\beta}(x,x') \;\longmapsto\; g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x,x')\,g(x')^\dagger \qquad \textit{(Corollary 4.64)},$$

and

$$\left(\hat{G}_\Lambda^{\alpha\beta}(x,x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x',x) \qquad \textit{(Lemma 4.66)}.$$

Consequently, the block obeys $\hat{\mathbf{G}}_\Lambda(x,x') \mapsto g(x)\,\hat{\mathbf{G}}_\Lambda(x,x')\,g(x')^\dagger$ and $\hat{\mathbf{G}}_\Lambda(x,x')^\dagger = \hat{\mathbf{G}}_\Lambda(x',x)$.

Remark 4.76 (Domain and well-posedness)**.** All operators act on spectrally regulated fibres $\mathrm{Ran}\,E^{(x)}([0,\lambda_{\mathrm{cutoff}}])$ (cf. eq. (4.303)), ensuring strong continuity of the transport along any C^1 path and the well-posedness of the assembled kernel (see Definition 4.48 and standard references).

Dialectic algebra action on indices and intertwining

Corollary 4.77 (Basic identities in component form)**.** *For all $\alpha,\beta\in\mathcal{I}$ and loci x,x',*

$$\left(\hat{G}_\Lambda^{\alpha\beta}(x,x')\right)^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x',x) \quad \textit{and} \quad \hat{G}_\Lambda^{\alpha\beta}(x,x') \mapsto g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x,x')\,g(x')^\dagger,$$

i.e. Hermitian symmetry and gauge covariance hold componentwise. Reference: *These follow from Lemma 4.66 and Corollary 4.64 (equivalently summarized in Corollary 4.75).*

Definition 4.78 (Fourfold Dialectic Algebra and local index representations)**.** Let $\mathfrak{D}$ denote the Fourfold Dialectic Algebra acting on the mode-label space at each locus. A *local representation* at x is a $*$-representation $\rho_x : \mathfrak{D} \to \mathrm{End}(\mathbb{C}^{\mathcal{I}}_x)$. We say the Fourfold selectors transform covariantly under ρ_x if for each $D \in \mathfrak{D}$,

$$\hat{\mathcal{F}}_\alpha(x) \;\longmapsto\; \sum_{\mu\in\mathcal{I}} \rho_x(D)_{\alpha\mu}\, \hat{\mathcal{F}}_\mu(x), \qquad \hat{\mathcal{F}}^\dagger_\alpha(x) \;\longmapsto\; \sum_{\mu\in\mathcal{I}} \hat{\mathcal{F}}^\dagger_\mu(x)\, \rho_x(D)^\dagger_{\mu\alpha}.$$

(An analogous representation $\rho_{x'}$ acts at x'.)

Proposition 4.79 (Intertwining of index actions with the channel kernel)**.** *Assume the selector covariance of Definition 4.78. Then the 4×4 block $\hat{\mathbf{G}}_\Lambda(x,x') = [\hat{G}^{\alpha\beta}_\Lambda(x,x')]_{\alpha,\beta\in\mathcal{I}}$ transforms under left/right actions of $\mathfrak{D}$ as*

$$\hat{\mathbf{G}}_\Lambda(x,x') \;\longmapsto\; \rho_x(D)^\dagger\, \hat{\mathbf{G}}_\Lambda(x,x')\, \rho_{x'}(D),$$

i.e. the α-index carries the left action (by $\rho_x(D)^\dagger$) and the β-index carries the right action (by $\rho_{x'}(D)$). Componentwise,

$$\hat{G}^{\alpha\beta}_\Lambda(x,x') \;\longmapsto\; \sum_{\mu,\nu\in\mathcal{I}} \rho_x(D)^\dagger_{\mu\alpha}\, \hat{G}^{\mu\nu}_\Lambda(x,x')\, \rho_{x'}(D)_{\nu\beta}.$$

Moreover, this index-algebra covariance is independent of (and commutes with) gauge covariance on the fibre: $\hat{\mathbf{G}}_\Lambda(x,x') \mapsto g(x)\, \hat{\mathbf{G}}_\Lambda(x,x')\, g(x')^\dagger$ (Corollary 4.64).

Proof. Linear substitution using the selector transformation at x and x' and the definition $\hat{G}^{\alpha\beta}_\Lambda = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$ (Definition 4.72) yields the component formula. Stacking components gives the block formula. Gauge covariance acts solely on the fibre operator $\mathcal{U}$, while $\rho_x, \rho_{x'}$ act on the index space, so the two actions commute. □

Remark 4.80 (Basis changes vs. gauge vs. dialectic algebra)**.** Three independent structures act on $\hat{\mathbf{G}}_\Lambda(x,x')$: (i) gauge on the fibre (endpoint conjugation), (ii) re-labelling/basis changes in $\mathbb{C}^{\mathcal{I}}$ (passive changes of $\mathcal{B}_x, \mathcal{B}_{x'}$; cf. Lemma 4.74), and (iii) active dialectic-algebra actions $\rho_x, \rho_{x'}$ on indices (this section). They compose without conflict and can be imposed in any order.

4.1.6 Block Matrix Representation Across Dialectic Modes

Definition 4.81 (Block matrix across dialectic modes)**.** With the ordered local frame $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$, the Fourfold correlator admits the operator-valued block matrix form

$$\hat{\mathbf{G}}_\Lambda(x,x') = \begin{bmatrix} \hat{G}^{00} & \hat{G}^{01} & \hat{G}^{0p} & \hat{G}^{0s} \\ \hat{G}^{10} & \hat{G}^{11} & \hat{G}^{1p} & \hat{G}^{1s} \\ \hat{G}^{p0} & \hat{G}^{p1} & \hat{G}^{pp} & \hat{G}^{ps} \\ \hat{G}^{s0} & \hat{G}^{s1} & \hat{G}^{sp} & \hat{G}^{ss} \end{bmatrix}, \qquad \hat{G}^{\alpha\beta} := \hat{G}^{\alpha\beta}_\Lambda(x,x'). \tag{4.24}$$

The *Twofold* (Symmetry–Antisymmetry) sector is the principal 2×2 block

$$\hat{\mathbf{G}}_{(0,1)}(x,x') = \begin{bmatrix} \hat{G}^{00} & \hat{G}^{01} \\ \hat{G}^{10} & \hat{G}^{11} \end{bmatrix}, \tag{4.25}$$

while the remaining blocks encode mixing with Parasymmetry (p) and Holosymmetry (s).

Corollary 4.82 (Blockwise Hermitian symmetry and gauge covariance)**.** *The block matrix satisfies*

$$\hat{\mathbf{G}}_\Lambda(x,x')^\dagger = \hat{\mathbf{G}}_\Lambda(x',x).$$
$$\hat{\mathbf{G}}_\Lambda(x,x') \mapsto g(x)\,\hat{\mathbf{G}}_\Lambda(x,x')\,g(x')^\dagger.$$

with the componentwise statements

$$\left(\hat{G}^{\alpha\beta}_\Lambda(x,x')\right)^\dagger = \hat{G}^{\beta\alpha}_\Lambda(x',x),$$
$$\hat{G}^{\alpha\beta}_\Lambda(x,x') \mapsto g(x)\,\hat{G}^{\alpha\beta}_\Lambda(x,x')\,g(x')^\dagger.$$

holding for all $\alpha,\beta \in \{0,1,p,s\}$ (Lemma 4.66 and Corollaries 4.64 and 4.75).

Remark 4.83 (Interpretation of matrix components)**.** With the block representation Definition 4.81 and eq. (4.24), the entries of $\hat{\mathbf{G}}_\Lambda(x,x')$ admit the following operational reading (cf. Remark 4.69):

Diagonal terms $\hat{G}^{\alpha\alpha}$:

Modal persistence—amplitudes preserving the dialectic mode along $x' \to x$ (self-coherence).

Off-diagonal terms $\hat{G}^{\alpha\beta}$, $\alpha \neq \beta$:

Dialectic transitions—mode-changing/interference amplitudes (e.g., $0 \leftrightarrow p$, $1 \leftrightarrow s$). These transform covariantly under gauge $\hat{G}^{\alpha\beta}_\Lambda \mapsto g(x)\hat{G}^{\alpha\beta}_\Lambda g(x')^\dagger$ (Corollary 4.82) and obey Hermitian symmetry $\left(\hat{G}^{\alpha\beta}_\Lambda\right)^\dagger = \hat{G}^{\beta\alpha}_\Lambda(x',x)$ (Lemma 4.66).

Block structure and algebra: (i) The Twofold subspace $\{0,1\}$ reproduces the classical dyad, i.e. the principal 2×2 block $\hat{\mathbf{G}}_{(0,1)}(x,x')$ (eq. (4.25)).

(ii) Cross-level blocks $\{0,1\} \leftrightarrow \{p,s\}$ implement algebraic intertwiners that couple the dyad to emergent modes, governing coherence flow and global (holosymmetric) information (cf. Definition 2.94 and eq. (3.36) and the index-action formalism in Definition 4.78 and Proposition 4.79).

Caution. As noted in Remark 4.71, $|p\rangle_x$ and $|s\rangle_x$ are not defined as linear combinations of $|0\rangle_x, |1\rangle_x$. The equal superposition $|+\rangle_x$ generates the parasymmetric *effect* $P^{(x)}_{\text{para}} = |+\rangle_x\langle+|$ within the Twofold sector, and is not identified with $|p\rangle_x$.

Definition 4.84 (Dialectic-complete selector system at an intermediate locus)**.** We say the selector family at y is *dialectically complete* (on the regulated fibre) if

$$\sum_{\gamma\in\{0,1,p,s\}} \hat{\mathcal{F}}_\gamma(y)\,\hat{\mathcal{F}}^\dagger_\gamma(y) = \mathbf{1} \quad \text{on } \operatorname{Ran} E^{(y)}([0,\lambda_{\text{cutoff}}]).$$

Proposition 4.85 (Block composition through an intermediate locus (conditional))**.** *Let $x \leftarrow y \leftarrow x'$ with paths γ_1,γ_2 such that $\gamma = \gamma_1\circ\gamma_2$. If the selector system at y is dialectically complete (Definition 4.84), then*

$$\hat{\mathbf{G}}_\Lambda(x,x';\gamma) \;=\; \hat{\mathbf{G}}_\Lambda(x,y;\gamma_1)\,\hat{\mathbf{G}}_\Lambda(y,x';\gamma_2),$$

i.e. block multiplication coincides with channel factorization. Componentwise, $\hat{G}^{\alpha\beta}_\Lambda(x,x') = \sum_\gamma \hat{G}^{\alpha\gamma}_\Lambda(x,y)\,\hat{G}^{\gamma\beta}_\Lambda(y,x')$. Reference: *Transport functoriality Proposition 4.52 and the tensor definition Definition 4.72.*

Remark 4.86 (Sector projections and classical slice)**.** Let $P_{(0,1)} = \mathrm{diag}(1,1,0,0)$ in the $\mathcal{I}$-ordering; then $P_{(0,1)}\,\hat{\mathbf{G}}_\Lambda(x,x')\,P_{(0,1)} = \hat{\mathbf{G}}_{(0,1)}(x,x')$ (eq. (4.25)). In regimes where interrogations commute or decoherence suppresses coherence across sectors, the off-diagonal blocks vanish (operationally), and the kernel *collapses* to the Twofold block—recovering the classical slice (cf. the discussion following Remark 4.69).

Duality-Collapse Regime at a Locus

Definition 4.87 (Duality-Collapse Regime at a Locus)**.** Fix a locus $\mathfrak{B}_x$. Write the modal fiber as $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = \mathrm{span}\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$, with the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda^{\alpha\beta}(x,x')$ and its Twofold restriction $\hat{G}_{(0,1)}$ as in Section 4.1.2 and Definition 4.1. We say that the *duality-collapse regime* holds at x (relative to a Holo-State $|\Omega_\Psi\rangle$) if:

(D1) **Block-diagonality (decoupling).** The off-block expectations vanish (exactly or within a fixed tolerance ϵ):

$$\langle\Omega_\Psi|\hat{G}_\Lambda^{\alpha\beta}(x,x')|\Omega_\Psi\rangle \approx 0 \quad \text{for all } \alpha\in\{0,1\},\ \beta\in\{p,s\} \text{ and } \alpha\leftrightarrow\beta,$$

uniformly for $x'\approx x$ along admissible transports.

(D2) **Inner-product realization.** The Twofold block induces a positive sesquilinear form on $\mathcal{H}_{\mathrm{mod}\,(0,1)}^{(\mathfrak{B}_x)} := \mathrm{span}\{|0\rangle_x, |1\rangle_x\}$ which is nondegenerate in the coincident limit and hence defines a fiberwise inner product.

Remark 4.88 (Meaning and consequences of the duality–collapse regime)**.** Under Definition 4.87, condition (D1) enforces expectation-level *block decoupling* between the Twofold sector $\{0,1\}$ and the emergent sector $\{p,s\}$:

$$\langle\Omega_\Psi|\hat{G}_\Lambda^{\alpha\beta}(x,x')|\Omega_\Psi\rangle \approx 0 \quad \text{for} \quad \alpha\in\{0,1\},\ \beta\in\{p,s\} \text{ and } \alpha\leftrightarrow\beta,$$

uniformly for $x'\approx x$. Hence, near x, the Born-evaluated Fourfold kernel reduces to its Twofold block $\hat{\mathbf{G}}_{(0,1)}(x,x')$ (cf. eq. (4.25)), up to $O(\epsilon)$.

Condition (D2) asserts that in the coincident limit $x'\to x$ this Twofold block induces a positive, nondegenerate sesquilinear form on $\mathcal{H}_{\mathrm{mod}\,(0,1)}^{(\mathfrak{B}_x)} = \mathrm{span}\{|0\rangle_x, |1\rangle_x\}$, thereby *realizing the local inner product* from the kernel (cf. *eq.* (4.6)). Together, (D1)–(D2) implement the "classical slice": Non-Contradiction/Excluded-Middle re-emerge on the dyad, while parasymmetric/holosymmetric channels carry no independent signal at x (cf. the narrative in Remark 4.69).

Gauge and transport notes. The statements are framed at the level of expectations, which are scalar and hence gauge invariant (see Corollary 4.82). The uniformity in $x'\approx x$ "along admissible transports" ensures locality and stability of the collapse under those path choices; no flatness assumption is required, only the expectation-level decoupling specified in (D1).

Corollary 4.89 (Effective Twofold kernel in the duality–collapse regime)**.** *Let the duality–collapse regime hold at $\mathfrak{B}_x$ relative to the Holo–State $|\Omega_\Psi\rangle$ in the sense of Definition 4.87. Define the Born–evaluated Fourfold kernel*

$$\overline{\mathbf{G}}_\Lambda(x,x') \;:=\; \Big[\ \langle\Omega_\Psi \mid \hat{G}_\Lambda^{\alpha\beta}(x,x') \mid \Omega_\Psi\rangle\ \Big]_{\alpha,\beta\in\{0,1,p,s\}}.$$

Then, uniformly for $x'\approx x$ along admissible transports:

(i) Cross–sector suppression
$\langle \Omega_\Psi \mid \hat{G}^{\alpha\beta}_\Lambda(x,x') \mid \Omega_\Psi \rangle = O(\epsilon)$ *for all* $\alpha \in \{0,1\},\ \beta \in \{p,s\}$ *and vice versa.*

(ii) Projection to the Twofold block
Let $P_{(0,1)} := \mathrm{diag}(1,1,0,0)$ *in the* $\mathcal{I}$*-ordering. Then*

$$\overline{\mathbf{G}}_\Lambda(x,x') \;=\; P_{(0,1)}\,\overline{\mathbf{G}}_\Lambda(x,x')\,P_{(0,1)} \;+\; O(\epsilon),$$

so, up to $O(\epsilon)$*, the effective Born kernel reduces to its Twofold block* $\hat{\mathbf{G}}_{(0,1)}(x,x')$ *of eq. (4.25).*

(iii) Inner product on the dyad (coincident limit)
As $x' \to x$*, the Twofold block* $\overline{\mathbf{G}}_{(0,1)}(x,x)$ *defines a positive, nondegenerate sesquilinear form on* $\mathrm{span}\{|0\rangle_x, |1\rangle_x\}$ *(by* (D2) *of Definition 4.87), hence a fibrewise inner product.*

(iv) Observable stability under projection
For any coefficient vectors $c^{(1)}, c^{(2)} \in \mathbb{C}^{\{0,1,p,s\}}$*,*

$$\Big(c^{(1)}\Big)^\dagger \overline{\mathbf{G}}_\Lambda(x,x')\,c^{(2)} \;=\; \Big(P_{(0,1)}c^{(1)}\Big)^\dagger \overline{\mathbf{G}}_\Lambda(x,x')\,\Big(P_{(0,1)}c^{(2)}\Big) \;+\; O(\epsilon),$$

so Born observables built from cross–sector blocks are $O(\epsilon)$ *near* x*.*

Gauge note. *All statements are formulated at the expectation level and are thus gauge invariant (cf. Corollary 4.82).*

Proposition 4.90 (Recovery of Ordinary Two-Level Quantum Kinematics)**.** *Under Definition 4.87, there exists an isometry* $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$ *such that for every Twofold–respecting effect* $E_{(0,1)}$ *and state* ρ *on the full fibre,*

$$\mathrm{Tr}\Big(E_{(0,1)}\,\rho\Big) \;=\; \mathrm{Tr}\Big(\,U^\dagger E_{(0,1)} U\,\rho_{(0,1)}\Big), \qquad \rho_{(0,1)} := U^\dagger \rho\, U,$$

i.e. all operational predictions on the Twofold sector coincide with those of an ordinary qubit state $\rho_{(0,1)} \in \mathcal{B}(\mathbb{C}^2)$ *with the standard Born rule.*

Proof of Proposition 4.90. Step 0 (Twofold sector and projection). Let $P_{(0,1)} := \mathrm{diag}(1,1,0,0)$ in the $\mathcal{I}$-ordering of $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ (Definition 4.81 and eq. (4.24)). By "Twofold–respecting effect" we mean an operator supported on the Twofold sector, $E_{(0,1)} = P_{(0,1)}E_{(0,1)}P_{(0,1)}$. Expectation–level gauge invariance holds throughout (Corollary 4.82).

Step 1 (Inner product from the kernel and orthonormalization). By (D2) of Definition 4.87 and the inner–product construction from the Fourfold kernel (cf. eq. (4.6) and Definition 4.73 and eq. (4.25)), the coincident–limit Twofold block induces a positive, nondegenerate sesquilinear form on $\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)} = \mathrm{span}\{|0\rangle_x, |1\rangle_x\}$. Choose an orthonormal pair $\{|e_0\rangle_x, |e_1\rangle_x\}$ for this form. Define $U : \mathbb{C}^2 \to \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$ by $U|0\rangle = |e_0\rangle_x$, $U|1\rangle = |e_1\rangle_x$. Then $U^\dagger U = \mathbf{1}_{\mathbb{C}^2}$ and $UU^\dagger = P_{(0,1)}$ on the Twofold sector, so U is an isometry.

Step 2 (Decoupling of cross–sector expectations). By (D1) of Definition 4.87 and Corollary 4.89, Born–evaluated cross–sector entries vanish (exactly, or up to $O(\epsilon)$) uniformly for $x' \approx x$. Consequently, for any state ρ and Twofold–respecting effect $E_{(0,1)}$,

$$\mathrm{Tr}\Big(E_{(0,1)}\,\rho\Big) = \mathrm{Tr}\Big(E_{(0,1)}\,P_{(0,1)}\rho P_{(0,1)}\Big)$$
(exact in the ideal regime; $+\,O(\epsilon)$ in the approximate one). (4.26)

Step 3 (Compression to $\mathbb{C}^2$ via the isometry). Using $UU^\dagger = P_{(0,1)}$,

$$\mathrm{Tr}\Big(E_{(0,1)}\, P_{(0,1)}\rho P_{(0,1)}\Big) = \mathrm{Tr}\Big(E_{(0,1)}\, UU^\dagger \rho\, UU^\dagger\Big) = \mathrm{Tr}\Big(U^\dagger E_{(0,1)} U \;\cdot\; U^\dagger \rho\, U\Big),$$

where we used cyclicity of the trace and $U^\dagger U = \mathbf{1}$. Set $\rho_{(0,1)} := U^\dagger \rho\, U \in \mathcal{B}(\mathbb{C}^2)$. Thus

$$\mathrm{Tr}\Big(E_{(0,1)}\,\rho\Big) = \mathrm{Tr}\Big(U^\dagger E_{(0,1)} U\;\rho_{(0,1)}\Big) \quad \text{(again, exactly or up to } O(\epsilon) \text{ as in Step 2).}$$

Step 4 (Standard qubit kinematics). The map $A \mapsto U^\dagger A U$ is a $*$-homomorphism on the Twofold corner and transports effects to $\mathcal{B}(\mathbb{C}^2)$. Hence, all Twofold operational predictions coincide with those obtained from the qubit state $\rho_{(0,1)}$ via the usual Born rule on $\mathbb{C}^2$. (Equivalently, in the GNS picture of Chapter 1, Born expectations are represented by traces in the anchored representation; see Proposition 4.17.)

This proves the claim. □

Remark 4.91 (Approximate regime and stability)**.** If (D1) holds with tolerance $\epsilon > 0$, the equality in Proposition 4.90 holds up to $O(\epsilon)$:

$$\mathrm{Tr}\Big(E_{(0,1)}\,\rho\Big) = \mathrm{Tr}\Big(U^\dagger E_{(0,1)} U\,\rho_{(0,1)}\Big) \;+\; O(\epsilon),$$

uniformly for $x' \approx x$ along admissible transports (Definition 4.87 and Corollary 4.89).

Remark 4.92 (Hierarchy of Collapses)**.** There are two conceptually distinct "collapse'' regimes, ordered by strength:

(A) Duality–collapse (quantum two–level limit). As in Definition 4.87, conditions (D1)–(D2) enforce (i) expectation–level decoupling between the Twofold sector $\{0,1\}$ and the emergent sector $\{p,s\}$, and (ii) realization of a positive, nondegenerate inner product on the Twofold fibre. Operationally, the Born–evaluated Fourfold kernel reduces (up to $O(\epsilon)$) to the Twofold block (Corollary 4.89), and *qubit kinematics* are recovered via the isometry $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$ (Proposition 4.90). Crucially, no commutativity inside the Twofold sector is assumed: off–diagonal Twofold amplitudes may persist, so intra–Twofold coherence is retained.

(B) Classical collapse (Boolean two–valued limit). This is a stronger, context–dependent limit in which, in addition to (D1)–(D2), *interrogations within the Twofold sector commute* (or decoherence fully suppresses the Twofold off–diagonals). Equivalently, there exist Twofold projectors P_T, P_A with

$$P_T P_A = 0, \qquad P_T + P_A = P_{(0,1)},$$

so Non–Contradiction and Excluded Middle hold on the Twofold slice (cf. the discussion surrounding the Twofold completeness statement in the prismatic/duality axioms). In this regime the Twofold block is diagonal in a common eigenbasis, and the Fourfold reduces to a classical two–valued "fortress'' (no interference anywhere).

Logical/operational ordering.

$$\begin{aligned} &\text{Fourfold (fully coherent)} \\ \Longrightarrow\ &\text{Duality–collapse (quantum Twofold)} \\ \Longrightarrow\ &\text{Classical collapse (Boolean Twofold).} \end{aligned}$$

The first arrow is a *representation–level reduction* (expectation–level decoupling and inner–product realization) that preserves Twofold coherence; the second arrow additionally removes intra–Twofold coherence by commutativity or complete dephasing. Typical generators of the second arrow include a Twofold dephasing channel $\mathcal{D}_{(0,1)}(\rho) = \sum_{\alpha\in\{T,A\}} P_\alpha \rho P_\alpha$, which enforces $P_T P_A = 0$ at the level of statistics.

Gauge/transport notes. Both regimes are framed at the level of expectations and are therefore gauge invariant (endpoint conjugations cancel; cf. Corollary 4.82). Uniformity in $x' \approx x$ "along admissible transports'' ensures locality and stability of the limiting behaviour; no flatness assumption is required.

Corollary 4.93 (Compatibility with the Atomic Prismatic)**.** *The passage to the Twofold sector is a* representation–level restriction *and does not alter the atomic prismatic unit* $\mathring{\mathbf{\Lambda}}$ *of Definition 1.5. In particular, properties* (a) No redefinition *and* (b) Closure as a unit *remain intact, and the invariance stated in Proposition 1.8 descends to the Twofold realization.*

Proof of Corollary 4.93. Let π denote the anchored (GNS) representation used for Born evaluation (cf. Proposition 4.17), and let $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}\,(0,1)}$ be the isometry from Proposition 4.90. Define the compressed Twofold representation

$$\pi_{(0,1)}(\,\cdot\,) \;:=\; U^\dagger\,\pi(\,\cdot\,)\,U \;:\; \text{Prismatic algebra} \longrightarrow \mathcal{B}(\mathbb{C}^2).$$

Then:

(i) *No redefinition.* The algebraic element $\mathring{\mathbf{\Lambda}}$ is unchanged; only its *representation* is restricted. Thus $\pi_{(0,1)}$ is obtained from π by isometric compression, not by modifying the algebra or its unit.

(ii) *Closure as a unit.* Since U is an isometry and π is unital,

$$\pi_{(0,1)}\Big(\mathring{\mathbf{\Lambda}}\Big) = U^\dagger\,\pi\Big(\mathring{\mathbf{\Lambda}}\Big)\,U = U^\dagger\,\mathbf{1}\,U = \mathbf{1}_{\mathbb{C}^2},$$

so the unit remains the unit after restriction.

(iii) *Descent of invariance.* For the duality automorphism D appearing in Proposition 1.8, we have

$$\pi_{(0,1)}\Big(\mathsf{D}(A)\Big) = U^\dagger \pi\Big(\mathsf{D}(A)\Big) U = U^\dagger\Big(\mathsf{D}\cdot\pi\Big)(A)\,U = \Big(\mathsf{D}\cdot\pi_{(0,1)}\Big)(A),$$

because compression by an isometry commutes with algebraic relations preserved by π. Hence the invariance identity of Proposition 1.8 holds verbatim for $\pi_{(0,1)}$, i.e. it *descends* to the Twofold realization.

This establishes the claim. □

Intuitive Understanding. The *Fourfold Inter-Modal Correlator* is best viewed as a gauge–covariant, four–channel, operator–valued propagator. It records how the four dialectic modes—*Symmetry (0)*, *Antisymmetry (1)*, *Parasymmetry (p)*, and *Holosymmetry (s)*—*transform and interfere* between two loci x' and x in the emergent configuration space $\mathcal{X}_q$

via the gauge–covariant transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ (Definitions 4.48 and 4.61, Proposition 4.54, and Corollary 4.64).

At its core, the correlator is a 4×4 matrix of channels. Each entry $\hat{G}_\Lambda^{\alpha\beta}(x, x')$ is the operator for the composite process: *imprint* mode β at x' using $\hat{\mathcal{F}}_\beta(x')$, *parallel–transport* to x with $\mathcal{U}(x \leftarrow x'; \gamma)$, then *read out* mode α at x using $\hat{\mathcal{F}}_\alpha^\dagger(x)$ (Definition 4.61). The block form $\hat{\mathbf{G}}_\Lambda(x, x')$ makes this structure explicit (eq. (4.24)). Its top–left 2×2 block is the *Twofold Correlator*, governing the classical dyad (Symmetry/Antisymmetry) (eq. (4.25)); the remaining blocks encode couplings of this dyad to the higher modes—coherent composition (Parasymmetry) and system–level invariants (Holosymmetry) (Remark 4.83, Definition 2.94, and eq. (3.36)).

Interpreting the entries gives a dynamic picture. Diagonal terms $\hat{G}^{\alpha\alpha}$ capture *modal persistence*—stability of a facet under transport—while off–diagonals $\hat{G}^{\alpha\beta}$ with $\alpha \neq \beta$ capture *modal transitions*—conversion or interference between facets (e.g., $0 \leftrightarrow p$, $1 \leftrightarrow s$) (Remark 4.83). As a whole, $\hat{\mathbf{G}}_\Lambda$ functions as a *relational kernel*: it exposes both local interference within the Twofold sector and cross–level couplings to parasymmetric and holosymmetric structure, while respecting Hermitian symmetry and gauge covariance ($\hat{\mathbf{G}}_\Lambda(x, x')^\dagger = \hat{\mathbf{G}}_\Lambda(x', x)$ and $\hat{\mathbf{G}}_\Lambda \mapsto g(x)\hat{\mathbf{G}}_\Lambda g(x')^\dagger$; see Lemma 4.66 and Corollary 4.82).

The correlator is deliberately *operator–valued*: it does not prematurely collapse quantum structure. By carrying residual degrees of freedom as operators, it lets *context*—state, locus, gauge—enter only at the final stage via expectations (GNS–anchored Born evaluation) (Proposition 4.17 and Definition 4.73). In the coincident limit $x' \to x$, expectations in the Holo–State produce Born–valued amplitudes that *define the inner product on the emergent modal fibre* (cf. (4.6)), so the correlator is not merely descriptive; it is *generative* of the local Hilbert geometry.

Classical reasoning appears as a limiting slice. When interrogations commute or decoherence suppresses phase information, cross–sector structure becomes inert and the 4×4 kernel *collapses to the Twofold block*, recovering the Thesis/Antithesis opposition (the "classical collapse''). By contrast, the *duality–collapse* regime only decouples $\{0, 1\}$ from $\{p, s\}$ at the level of expectations while retaining quantum coherence within the Twofold subspace—thereby recovering ordinary qubit kinematics without imposing commutativity (Definition 4.87, Corollary 4.89, Proposition 4.90, and Remark 4.92). In regimes where coherence and global invariants matter, the full Fourfold kernel is indispensable: a gauge–aligned, multi–port propagator that tells how logical facets persist, convert, and entangle across loci—and, through its expectations, carves the geometry of the emergent quantum space they inhabit (Proposition 4.54, Definition 4.48, and Remark 4.83).

4.1.7 Algebraic Structure and Graded Dynamics of the Fourfold Inter-Modal Correlator

Dialectic grading of modal indices

Definition 4.94 (Dialectic $\mathbb{Z}_2^2$-grading of modes and channel components)**.** Let the mode set be $\mathcal{I} = \{0, 1, p, s\}$ (Symmetry, Antisymmetry, Parasymmetry, Holosymmetry). Assign a

bidegree

$$\deg(0) = (0,0), \qquad \deg(1) = (1,0), \qquad \deg(p) = (1,1), \qquad \deg(s) = (0,1),$$

so that p behaves algebraically as the composite of the two fundamental oppositions 1 and s. For channel components $\hat{G}^{\alpha\beta}(x,x')$ (cf. eq. (4.22)), define the *colored matrix–unit* grading by

$$\deg\left(\hat{G}^{\alpha\beta}\right) := \deg(\alpha) + \deg(\beta) \ \in \ \mathbb{Z}_2 \times \mathbb{Z}_2. \tag{4.27}$$

Whenever the product XY of homogeneous components is defined (index–wise), degrees add under composition:

$$\deg(XY) = \deg(X) + \deg(Y) \ \in \ \mathbb{Z}_2 \times \mathbb{Z}_2.$$

Lemma 4.95 (Even degree implies bracket equivalence)**.** *If* $\deg A = (0,0)$*, then for every homogeneous* B *one has* $[A,B]_{\mathrm{gr}} = [A,B]$.

Proof. Immediate from the definition $[A,B]_{\mathrm{gr}} = AB - (-1)^{\langle \deg A, \deg B\rangle} BA$ and $\langle (0,0), \deg B\rangle = 0$. □

Corollary 4.96. *If* $\deg A = (0,0)$*, then* $[A,B]_{\mathrm{gr}} = [A,B]$ *for every (not necessarily homogeneous)* B.

Proof. Decompose $B = \sum_j B_j$ into homogeneous components and use linearity with Lemma 4.95. □

Mode	Degree $\deg(\alpha)$	Heuristic role
0 (Symmetry)	$(0,0)$	identity sector
1 (Antisymmetry)	$(1,0)$	primary opposition
p (Parasymmetry)	$(1,1)$	composite of oppositions
s (Holosymmetry)	$(0,1)$	independent global duality

Definition 4.97 (Dialectic grading on channels)**.** With deg as above, the block matrix $\hat{\mathbf{G}}_\Lambda(x,x')$ (Definition 4.81 and eq. (4.24)) is a $\mathbb{Z}_2^2$-graded matrix algebra by componentwise degree $\deg(\hat{G}^{\alpha\beta}) = \deg(\alpha) + \deg(\beta)$.

Lemma 4.98 (Compatibility of grading with adjoint, gauge, and composition)**.** *For all* $\alpha, \beta \in \mathcal{I}$ *and all* x, x'*:*

(i) Adjoint
$\left(\hat{G}^{\alpha\beta}_\Lambda(x,x')\right)^\dagger = \hat{G}^{\beta\alpha}_\Lambda(x',x)$ *(Lemma 4.66), and* $\deg\left((\hat{G}^{\alpha\beta})^\dagger\right) = \deg(\alpha) + \deg(\beta) = \deg(\hat{G}^{\alpha\beta})$.

(ii) Gauge
Under $\hat{G}^{\alpha\beta}_\Lambda(x,x') \mapsto g(x)\hat{G}^{\alpha\beta}_\Lambda(x,x')g(x')^\dagger$ *(Corollaries 4.64 and 4.82), the degree is unchanged.*

(iii) Composition

If $x \leftarrow y \leftarrow x'$ and the selector family at y is dialectically complete (Definition 4.84), then

$$\hat{G}^{\alpha\beta}_{\Lambda}(x,x') = \sum_{\gamma\in\mathcal{I}} \hat{G}^{\alpha\gamma}_{\Lambda}(x,y)\,\hat{G}^{\gamma\beta}_{\Lambda}(y,x') \quad \textit{(Proposition 4.85)},$$

and each summand satisfies $\deg\left(\hat{G}^{\alpha\gamma}\hat{G}^{\gamma\beta}\right) = \deg(\alpha) + \deg(\beta)$.

Proof of Lemma 4.98. We prove (i)–(iii) in turn, using the grading of Definition 4.94 and the channel/operator laws established in Chapter 4.

(i) Adjoint. By Hermitian symmetry of channels, $\left(\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\right)^{\dagger} = \hat{G}^{\beta\alpha}_{\Lambda}(x',x)$ (Lemma 4.66). Hence, using the definition of the bidegree (Definition 4.94),

$$\deg\Big((\hat{G}^{\alpha\beta})^{\dagger}\Big) = \deg(\beta) + \deg(\alpha) = \deg(\alpha) + \deg(\beta) = \deg\Big(\hat{G}^{\alpha\beta}\Big),$$

since addition in $\mathbb{Z}_2^2$ is commutative.

(ii) Gauge. Under a local gauge $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, each channel transforms by endpoint conjugation, $\hat{G}^{\alpha\beta}_{\Lambda}(x,x') \mapsto g(x)\,\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\,g(x')^{\dagger}$ (Corollary 4.64). Because the grading depends only on the *mode labels* (α,β) and not on fibrewise conjugation (Definition 4.94), one has $\deg\Big(g(x)\,\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\,g(x')^{\dagger}\Big) = \deg\Big(\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\Big)$. Thus degree is gauge invariant.

(iii) Composition. Let $x \leftarrow y \leftarrow x'$ and pick composable path segments so that $\gamma = \gamma_1 \circ \gamma_2$ with $x \xleftarrow{\gamma_1} y$ and $y \xleftarrow{\gamma_2} x'$. By transport functoriality (Proposition 4.52 and eq. (4.14)), $\mathcal{U}(x \leftarrow x';\gamma) = \mathcal{U}(x \leftarrow y;\gamma_1)\,\mathcal{U}(y \leftarrow x';\gamma_2)$. Insert at the intermediate locus y the dialectically complete resolution of the identity ($\sum_{\mu\in\mathcal{I}} \hat{\mathcal{F}}_{\mu}(y)\hat{\mathcal{F}}^{\dagger}_{\mu}(y) = \mathbf{1}$; cf. Definition 4.84) into the Fourfold channel definition (Definition 4.61):

$$\begin{aligned}
\hat{G}^{\alpha\beta}_{\Lambda}(x,x') &= \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_{\beta}(x') \\
&= \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\mathcal{U}(x \leftarrow y;\gamma_1)\left(\sum_{\mu\in\mathcal{I}} \hat{\mathcal{F}}_{\mu}(y)\hat{\mathcal{F}}^{\dagger}_{\mu}(y)\right)\mathcal{U}(y \leftarrow x';\gamma_2)\,\hat{\mathcal{F}}_{\beta}(x') \\
&= \sum_{\mu\in\mathcal{I}} \Big[\hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\mathcal{U}(x \leftarrow y;\gamma_1)\,\hat{\mathcal{F}}_{\mu}(y)\Big]\Big[\hat{\mathcal{F}}^{\dagger}_{\mu}(y)\,\mathcal{U}(y \leftarrow x';\gamma_2)\,\hat{\mathcal{F}}_{\beta}(x')\Big] \\
&= \sum_{\mu\in\mathcal{I}} \hat{G}^{\alpha\mu}_{\Lambda}(x,y)\,\hat{G}^{\mu\beta}_{\Lambda}(y,x'),
\end{aligned}$$

which is the claimed block–composition identity (Proposition 4.85).

For the degree of each summand, use Definition 4.94:

$$\begin{aligned}
\deg\Big(\hat{G}^{\alpha\mu}\hat{G}^{\mu\beta}\Big) &= \deg(\hat{G}^{\alpha\mu}) + \deg(\hat{G}^{\mu\beta}) \\
&= \Big(\deg\alpha + \deg\mu\Big) + \Big(\deg\mu + \deg\beta\Big) \\
&= \deg\alpha + \underbrace{2\,\deg\mu}_{=0} + \deg\beta,
\end{aligned} \tag{4.28}$$

where $2\deg\mu = 0$ in $\mathbb{Z}_2^2$. Hence $\deg\Big(\hat{G}^{\alpha\mu}\hat{G}^{\mu\beta}\Big) = \deg(\alpha) + \deg(\beta)$, as stated.

This completes the proof. □

Proposition 4.99 (Selection rules and sector patterns)**.** *In the ordered basis* $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$*:*

(a) *The Twofold block* $\hat{\mathbf{G}}_{(0,1)}(x,x')$ *(eq. (4.25)) contains only degrees* $(0,0)$ *(diagonals) and* $(1,0)$ *(off–diagonals).*

(b) *Blocks that couple* $\{0,1\}$ *to* $\{p,s\}$ *carry degrees with second component* 1 *(they probe the holosymmetric axis).*

(c) *Under block composition through* y *(Proposition 4.85), every matrix element* $\hat{G}^{\alpha\beta}_{\Lambda}(x,x')$ *has total degree* $\deg(\alpha)+\deg(\beta)$ *independently of the intermediate index* γ*.*

Proof of Proposition 4.99. Throughout we use the $\mathbb{Z}_2^2$-grading of Definition 4.94 with $\deg(0) = (0,0)$, $\deg(1) = (1,0)$, $\deg(p) = (1,1)$, $\deg(s) = (0,1)$, and $\deg\big(\hat{G}^{\alpha\beta}\big) = \deg(\alpha)+\deg(\beta)$.

(a) Twofold block degrees. In the Twofold block $\alpha,\beta \in \{0,1\}$ (eq. (4.25)). For diagonals $\alpha=\beta$, $\deg(\hat{G}^{\alpha\alpha}) = \deg(\alpha)+\deg(\alpha) = 2\deg(\alpha) = (0,0)$ in $\mathbb{Z}_2^2$. For off–diagonals, $\deg(\hat{G}^{01}) = (0,0)+(1,0) = (1,0)$ and $\deg(\hat{G}^{10}) = (1,0)+(0,0) = (1,0)$. Hence the block contains only $(0,0)$ on the diagonal and $(1,0)$ off–diagonal.

(b) Couplings $\{0,1\} \leftrightarrow \{p,s\}$. Take $\alpha \in \{0,1\}$ and $\beta \in \{p,s\}$ (or vice versa). The second component of the degree is $\deg_2(\alpha)+\deg_2(\beta) \pmod 2$. Since $\deg_2(0) = \deg_2(1) = 0$ and $\deg_2(p) = \deg_2(s) = 1$, one has $\deg_2(\hat{G}^{\alpha\beta}) = 1$. Thus every such block element has second component 1, i.e. it probes the holosymmetric axis.

(c) Degree under block composition. By the block–composition identity through an intermediate locus y (Proposition 4.85),

$$\hat{G}^{\alpha\beta}_{\Lambda}(x,x') = \sum_{\gamma\in\mathcal{I}} \hat{G}^{\alpha\gamma}_{\Lambda}(x,y)\,\hat{G}^{\gamma\beta}_{\Lambda}(y,x').$$

For each summand, Lemma 4.98(iii) gives

$$\begin{aligned}\deg\big(\hat{G}^{\alpha\gamma}\hat{G}^{\gamma\beta}\big) &= \deg(\hat{G}^{\alpha\gamma}) + \deg(\hat{G}^{\gamma\beta}) \\ &= \big(\deg\alpha + \deg\gamma\big) + \big(\deg\gamma + \deg\beta\big) \\ &= \deg\alpha + \underbrace{2\,\deg\gamma}_{=0} + \deg\beta, \end{aligned} \tag{4.29}$$

so $\deg\big(\hat{G}^{\alpha\gamma}\hat{G}^{\gamma\beta}\big) = \deg(\alpha)+\deg(\beta)$, independently of γ. This establishes the stated selection rule for every matrix element of the composed block.

Items (a)–(c) together prove the proposition. □

Definition 4.100 (Graded sign and graded commutator (optional))**.** Equip $\mathbb{Z}_2^2$ with the standard bilinear form $\langle (a_1,a_2),(b_1,b_2)\rangle := a_1b_1 + a_2b_2 \pmod 2$. For homogeneous components X, Y define

$$[X,Y]_{\mathrm{g}} := XY - (-1)^{\langle \deg X, \deg Y\rangle} YX.$$

Then $[\,\cdot,\cdot\,]_{\mathrm{g}}$ is bilinear, graded–antisymmetric, and satisfies the graded Jacobi identity on the associative algebra generated by the $\hat{G}^{\alpha\beta}$.

Remark 4.101 (What the grading means (and what it does not))**.** The $\mathbb{Z}_2^2$–grading is a bookkeeping structure on *mode labels* and their channels, not a fermionic parity on physical operators. It organizes how components mix under composition, adjoint, and gauge (Lemma 4.98) and clarifies which blocks probe parasymmetric vs. holosymmetric content (Remark 4.83). In particular, the graded selection rules in Proposition 4.99 are compatible with transport functoriality (Proposition 4.52), block composition (Proposition 4.85), and Hermitian/gauge properties (Lemma 4.66 and Corollary 4.82).

Corollary 4.102 (Adjoint and block grading)**.** *For the graded components of Definition 4.94 one has:*

(i) Adjoint preserves degree

Using Hermitian symmetry $\big(\hat{G}^{\alpha\beta}(x,x')\big)^\dagger = \hat{G}^{\beta\alpha}(x',x)$ *(Lemma 4.66),*

$$\deg\Big((\hat{G}^{\alpha\beta})^\dagger\Big) = \deg(\beta) + \deg(\alpha) = \deg(\alpha) + \deg(\beta) = \deg\Big(\hat{G}^{\alpha\beta}\Big).$$

(ii) Diagonal evenness

For $\alpha = \beta$, $\deg(\hat{G}^{\alpha\alpha}) = \deg(\alpha) + \deg(\alpha) = 0$ *in* $\mathbb{Z}_2^2$, *so all diagonals are even* $(0,0)$.

(iii) Off–diagonal spectrum

For $\alpha \neq \beta$, $\deg(\hat{G}^{\alpha\beta}) \in \{(1,0),(0,1),(1,1)\}$.

Proof. (i) is immediate from Lemma 4.66 and commutativity of addition in $\mathbb{Z}_2^2$. (ii) follows since $2\deg(\alpha) = 0$ in $\mathbb{Z}_2^2$. (iii) is the complement of $(0,0)$ in the degree set for $\alpha \neq \beta$. □

Graded $*$-algebra of channels and super–bracket

Definition 4.103 (Graded $*$-algebra of channel components)**.** Let $\mathsf{G} := \operatorname{span}\{\hat{G}^{\alpha\beta}(x,x') : \alpha,\beta \in \mathcal{I}\} \subset \mathcal{B}(\mathcal{H}_{\mathrm{em}})$, with degree $\deg(\hat{G}^{\alpha\beta}) = \deg(\alpha) + \deg(\beta) \in \mathbb{Z}_2^2$ from Definition 4.94. Equip G with:

- *Product:* ordinary operator composition (degree–additive).
- *Adjoint:* $(\cdot)^\dagger$ with $(\hat{G}^{\alpha\beta})^\dagger = \hat{G}^{\beta\alpha}$ (Lemma 4.66).
- *Graded bracket:*

$$[X,Y]_{\mathrm{gr}} := XY - (-1)^{\langle \deg X, \deg Y\rangle} YX, \qquad \langle (a_1,a_2),(b_1,b_2)\rangle := a_1b_1 + a_2b_2 \pmod 2. \tag{4.30}$$

Proposition 4.104 (Color Lie $*$-algebra structure)**.** $(\mathsf{G}, [\cdot,\cdot]_{\mathrm{gr}}, (\cdot)^\dagger)$ *is a* $\mathbb{Z}_2^2$-color *Lie* $*$*-algebra:*

(a) *(*Graded skew-symmetry*)* $[X,Y]_{\mathrm{gr}} = -(-1)^{\langle \deg X, \deg Y\rangle}[Y,X]_{\mathrm{gr}}$.

(b) *(*Graded Jacobi*) For homogeneous* X,Y,Z,

$$\begin{aligned}&(-1)^{\langle \deg X, \deg Z\rangle}[X,[Y,Z]_{\mathrm{gr}}]_{\mathrm{gr}}\\ &+ (-1)^{\langle \deg Y, \deg X\rangle}[Y,[Z,X]_{\mathrm{gr}}]_{\mathrm{gr}}\\ &+ (-1)^{\langle \deg Z, \deg Y\rangle}[Z,[X,Y]_{\mathrm{gr}}]_{\mathrm{gr}} = 0.\end{aligned} \tag{4.31}$$

(c) *(*$*$-compatibility*)* $[X,Y]_{\mathrm{gr}}^\dagger = -(-1)^{\langle \deg X, \deg Y\rangle}[X^\dagger, Y^\dagger]_{\mathrm{gr}}$.

Proof. All identities are standard for the graded commutator on a $\mathbb{Z}_2^2$-graded associative $*$-algebra. (a) is immediate from (4.30). For (b), associativity of the product and bilinearity of $\langle\cdot,\cdot\rangle$ yield the color Jacobi identity by the usual cancellation in the sum of six terms. For (c), use $(XY)^\dagger = Y^\dagger X^\dagger$ and Lemma 4.66:

$$\begin{aligned}[X,Y]_{\mathrm{gr}}^\dagger &= (XY)^\dagger - (-1)^{\langle \deg X, \deg Y\rangle}(YX)^\dagger = Y^\dagger X^\dagger - (-1)^{\langle \deg X, \deg Y\rangle} X^\dagger Y^\dagger \\ &= -\Big(X^\dagger Y^\dagger - (-1)^{\langle \deg X^\dagger, \deg Y^\dagger\rangle} Y^\dagger X^\dagger\Big) = -\,(-1)^{\langle \deg X, \deg Y\rangle}[X^\dagger, Y^\dagger]_{\mathrm{gr}},\end{aligned}$$

since $\deg(X^\dagger) = \deg(X)$ by Lemma 4.98(i). □

Corollary 4.105 (Selection rules: even/odd mixing)**.** *Let $X, Y \in \mathsf{G}$ be homogeneous.*

(i) *If $\deg X = (0,0)$ or $\deg Y = (0,0)$, then $[X,Y]_{\mathrm{gr}} = [X,Y]$ (ordinary commutator).*

(ii) *If $\deg X = \deg Y \in \{(1,0),(0,1),(1,1)\}$, then $[X,Y]_{\mathrm{gr}} = XY + YX$ (graded anticommutator).*

(iii) *If $\deg X$ and $\deg Y$ are distinct nontrivial colors with $\langle \deg X, \deg Y\rangle = 0$ (e.g. $(1,0)$ with $(0,1)$), then $[X,Y]_{\mathrm{gr}} = [X,Y]$ (ordinary commutator).*

(iv) *If $\langle \deg X, \deg Y\rangle = 1$ (e.g. $(1,0)$ with $(1,1)$ or $(0,1)$ with $(1,1)$), then $[X,Y]_{\mathrm{gr}} = XY + YX$.*

Lemma 4.106 (Gauge covariance of the graded algebra)**.** *Under a local gauge $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, $\hat{G}^{\alpha\beta}(x,x') \mapsto g(x)\hat{G}^{\alpha\beta}(x,x')g(x')^\dagger$ (Corollary 4.64), one has for all $X, Y \in \mathsf{G}$:*

$$[gXg^\dagger,\ gYg^\dagger]_{\mathrm{gr}} = g\,[X,Y]_{\mathrm{gr}}\,g^\dagger, \qquad \deg(gXg^\dagger) = \deg X.$$

Proof. Degree invariance is Lemma 4.98(ii). For the bracket, use multiplicativity of conjugation and (4.30):

$$\begin{aligned}[gXg^\dagger, gYg^\dagger]_{\mathrm{gr}} &= gXYg^\dagger - (-1)^{\langle \deg X, \deg Y\rangle} gYXg^\dagger \\ &= g\Big(XY - (-1)^{\langle \deg X, \deg Y\rangle} YX\Big)g^\dagger \\ &= g[X,Y]_{\mathrm{gr}}g^\dagger.\end{aligned}$$

□

Two structural consequences

Proposition 4.107 (Even core acts by degree-0 derivations)**.** *For every locus and indices $\alpha, \beta, \gamma \in \mathcal{I}$, the diagonal channels are even $\deg(\hat{G}^{\alpha\alpha}) = (0,0)$ (Corollary 4.102) and act by ordinary derivations on all colored components:*

$$[\hat{G}^{\alpha\alpha}, \hat{G}^{\beta\gamma}]_{\mathrm{gr}} = [\hat{G}^{\alpha\alpha}, \hat{G}^{\beta\gamma}] \quad \text{and} \quad [\hat{G}^{\alpha\alpha}, XY]_{\mathrm{gr}} = [\hat{G}^{\alpha\alpha}, X]_{\mathrm{gr}}\,Y + X\,[\hat{G}^{\alpha\alpha}, Y]_{\mathrm{gr}}$$

for any homogeneous $X, Y \in \mathsf{G}$ (Definition 4.103). In particular, self-persistence amplitudes $\hat{G}^{\alpha\alpha}$ control the phase/magnitude of transition channels without inducing color flips.

Proof. By Corollary 4.102, $\deg(\hat{G}^{\alpha\alpha}) = (0,0)$. Thus the graded bracket with any Z reduces to the ordinary commutator: $[\hat{G}^{\alpha\alpha}, Z]_{\mathrm{gr}} = [\hat{G}^{\alpha\alpha}, Z]$ (Corollary 4.105(i)). The derivation law follows from $[D, XY] = [D,X]Y + X[D,Y]$ for the ordinary commutator applied with $D = \hat{G}^{\alpha\alpha}$. No color flip occurs because $\deg(D) = (0,0)$. □

Proposition 4.108 (Compatibility with the Fourfold Dialectic Algebra)**.** *Let L, R act on mode indices as in the Fourfold Dialectic Algebra (cf. Definition 1.5), and define the left/right action on the block kernel by*

$$(L \cdot \hat{\mathbf{G}}_\Lambda \cdot R^\dagger)^{\alpha\beta} = \sum_{\gamma,\delta\in\mathcal{I}} L^\alpha{}_\gamma \, \hat{G}_\Lambda^{\gamma\delta}(x,x') \, (R^\dagger)_\delta{}^\beta.$$

If L and R are degree-preserving on indices (homogeneous of total degree 0 with respect to Definition 4.94), then for each term in the sum

$$\deg\Big(L^\alpha{}_\gamma \, \hat{G}^{\gamma\delta} \, (R^\dagger)_\delta{}^\beta\Big) = \deg(\alpha) + \deg(\beta),$$

so the graded decomposition is preserved and the block structure respected.

Proof. Write the index matrix units as $E^\alpha{}_\gamma$ and endow them with $\deg(E^\alpha{}_\gamma) = \deg(\alpha) + \deg(\gamma)$ (the same color-addition rule as Definition 4.94). A degree-0 L (resp. $R^\dagger$) is a linear combination of homogeneous $E^\alpha{}_\gamma$ (resp. $E_\delta{}^\beta$) with $\deg(E^\alpha{}_\gamma) = \deg(\alpha) + \deg(\gamma)$ (resp. $\deg(E_\delta{}^\beta) = \deg(\delta) + \deg(\beta)$). For a homogeneous summand,

$$\deg\Big(E^\alpha{}_\gamma \, \hat{G}^{\gamma\delta} \, E_\delta{}^\beta\Big) = \Big(\deg\alpha + \deg\gamma\Big) + \Big(\deg\gamma + \deg\delta\Big) + \Big(\deg\delta + \deg\beta\Big) = \deg\alpha + \deg\beta,$$

since $2\deg\gamma = 2\deg\delta = 0$ in $\mathbb{Z}_2^2$. Hence each term (and thus the sum) has total degree $\deg(\alpha) + \deg(\beta)$. This matches the selection rule under composition (Proposition 4.99(c), via Proposition 4.85). □

Optional model postulates (graded dynamics)

Definition 4.109 (Word in the channel algebra)**.** Fix loci $x_0, \ldots, x_k$ and consider the generators $\{\hat{G}_\Lambda^{\alpha_i\beta_i}(x_i, x_{i-1})\}_{i=1}^k$ of the graded $*$-algebra G (Definitions 4.94 and 4.103). A *word* (of length k) is a well-typed product

$$W \;=\; X_k X_{k-1} \cdots X_1, \qquad X_i \in \{\hat{G}_\Lambda^{\alpha_i\beta_i}(x_i, x_{i-1})\},$$

where consecutive endpoints match (so composition is defined) and multiplication is ordinary operator composition (Proposition 4.85). The empty word has length 0 and equals the identity. The degree is additive: $\deg W = \sum_{i=1}^k \deg(X_i)$ (Definition 4.94 and Lemma 4.98), and under gauge, $W \mapsto g(x_k)\, W\, g(x_0)^\dagger$ (Corollary 4.64). A *reduced word* is one simplified using the algebraic relations in force (e.g. nilpotencies, centrality, orthogonality), yielding a normal form.

Remark 4.110 (Words as channel histories)**.** Intuitively, a *word* (cf. Definition 4.109) is a single "history'' obtained by stacking channel factors in sequence when their endpoints match. Its length is the number of factors; its degree is the sum of the factor degrees (Definition 4.94 and Lemma 4.98); and under gauge it conjugates at the endpoints (Corollary 4.64).

- **Example (edge history).** Along the p–s edge, $W = \hat{G}^{ps}\hat{G}^{sp}\hat{G}^{ps}$ is a well-typed word of length 3, representing a $s \to p \to s \to p$ conversion sequence across an intermediate locus (Proposition 4.85).

- **Local truncations from nilpotency.** Under Theorem 4.123 we have $(\hat{G}^{ps})^2 = (\hat{G}^{sp})^2 = 0$. Therefore any word containing two consecutive $\hat{G}^{ps}$ (or two consecutive $\hat{G}^{sp}$) factors collapses to 0, yielding the series–truncation effect stated in Corollary 4.125.
- **Stronger differential scenario.** In the stronger variant of (N1) (Definition 4.119) where the graded differential d satisfies $\mathsf{d}^2 = 0$ on both stalks p and s, the *mixed* back–to–back composites also vanish: $\hat{G}^{ps}\hat{G}^{sp} = 0 = \hat{G}^{sp}\hat{G}^{ps}$. Then any nonempty word in $\{\hat{G}^{ps}, \hat{G}^{sp}\}$ reduces to a linear combination of single–step terms (and possibly the identity), exactly as used in the series–truncation arguments.
- **Degree bookkeeping.** Because $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1,0)$ (Definition 4.94), a word with an odd number of $p \leftrightarrow s$ steps has degree $(1,0)$, while an even number yields total degree $(0,0)$. This parity explains why square terms are the first to vanish in the nilpotent regime.

Postulate 4.1 (Central (or approximately central) holosymmetry)**.** *The holosymmetric self-channel $\hat{G}^{ss}(x,x')$ is central (or central up to controlled corrections): $[\hat{G}^{ss}, \hat{X}]_{\mathrm{gr}} \approx 0$ for all channel combinations $\hat{X}$.*

Definition 4.111 (Central holosymmetry hypotheses)**.** Let $\mathsf{G} = \mathrm{span}\{\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\}_{\alpha,\beta\in\mathcal{I}} \subset \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ be the graded channel $*$-algebra with bracket $[\cdot,\cdot]_{\mathrm{gr}}$ from Definition 4.103. We say that one of the following hypotheses holds:

(C1) Group-averaged holosymmetry (Schur). There exists a compact (or unimodular) implementation group H acting unitarily fibrewise, $U_x : H \to \mathrm{U}(\mathcal{H}_{\mathrm{em}}(x))$, such that: (i) the connection is H-invariant and the transporter is H-equivariant,

$$U_x(h)\,\mathcal{U}(x \leftarrow x';\gamma) = \mathcal{U}(x \leftarrow x';\gamma)\,U_{x'}(h) \quad \forall h \in H, \tag{4.32}$$

(ii) the holosymmetric selector is the H-average of a seed selector $\hat{\mathcal{F}}_0$:

$$\hat{\mathcal{F}}_s(x) \;:=\; \int_H U_x(h)\,\hat{\mathcal{F}}_0(x)\,U_x(h)^\dagger \,\mathrm{d}h, \tag{4.33}$$

and (iii) the representation of H on the relevant subspace of $\mathcal{H}_{\mathrm{em}}(x)$ is irreducible.

(C2) Superselection of the holosymmetric charge. There is a self-adjoint charge Q with spectral projectors $\{P_\chi\}$ such that the holosymmetric mode s corresponds to a sector projector P_s, and the observable/channel algebra acts within the commutant of Q: $\mathsf{G} \subseteq \{Q\}' = \{X : [X,Q] = 0\}$.

(C3) Flat, topological reduction. On a simply connected neighbourhood $U \subset \mathcal{X}_q$ with $\mathcal{F} = 0$ (Proposition 4.59), the holosymmetric selector is a gauge-invariant functional of holonomy classes; since all holonomies trivialize on U, there exist endpoint maps $g : U \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ with $\mathcal{U}(x \leftarrow x';\gamma) = g(x)g(x')^\dagger$ and a *scalar* kernel $c(x,x') \in \mathbb{C}$ such that

$$\hat{G}^{ss}_{\Lambda}(x,x') = \hat{\mathcal{F}}_s^\dagger(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x') = g(x)\,\Big(c(x,x')\,\mathbf{1}\Big)\,g(x')^\dagger. \tag{4.34}$$

Definition 4.112 (Centrality defect)**.** Under the hypotheses of Definition 4.111, define the (uniform) centrality defect

$$\delta \;:=\; \sup_{\|X\|=1} \Big\| [\,\hat{G}^{ss}_{\Lambda},\, X\,]_{\mathrm{gr}} \Big\| \;\in [0,\infty).$$

We say holosymmetry is δ-*central* if this bound is finite (and small).

Proposition 4.113 (Central holosymmetry under group averaging)**.** *If* (C1) *of Definition 4.111 holds, then* $\hat{G}^{ss}_{\Lambda}(x,x')$ *is proportional to the identity on the* H*-irreducible subspace and hence lies in the center of* G*:*

$$[\hat{G}^{ss}_{\Lambda}(x,x'),\, X]_{\mathrm{gr}} = 0 \quad \textit{for all } X \in \mathsf{G}.$$

Proof. By Definition 4.61, $\hat{G}^{ss}_{\Lambda} = \hat{\mathcal{F}}^{\dagger}_{s}(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_{s}(x')$. Insert (4.33) at both endpoints and use the equivariance (4.32) to obtain

$$\hat{G}^{ss}_{\Lambda}(x,x') = \int_{H\times H}\Big(U_x(h)\,\hat{\mathcal{F}}^{\dagger}_{0}(x)\,U_x(h)^{\dagger}\Big)\,\mathcal{U}\,\Big(U_{x'}(k)\,\hat{\mathcal{F}}_{0}(x')\,U_{x'}(k)^{\dagger}\Big)\,\mathrm{d}h\,\mathrm{d}k.$$

A change of variables and averaging on the right shows $\hat{G}^{ss}_{\Lambda}$ intertwines the H-actions at x and x'. On an H-irreducible subspace, Schur's lemma yields $\hat{G}^{ss}_{\Lambda}(x,x') = \lambda(x,x')\,\mathbf{1}$. As a diagonal channel, $\deg(\hat{G}^{ss}) = (0,0)$ (Corollary 4.102), so the graded commutator reduces to the ordinary commutator and hence vanishes with any $X \in \mathsf{G}$. □

Proposition 4.114 (Central holosymmetry under superselection)**.** *If* (C2) *of Definition 4.111 holds, then* $\hat{G}^{ss}_{\Lambda}(x,x') \in \{Q\}'$ *and* $[\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X\,]_{\mathrm{gr}} = 0$ *for all* $X \in \mathsf{G}$.

Proof. By hypothesis, $\mathsf{G} \subseteq \{Q\}'$. Since the holosymmetric channel is confined to the s-sector, $\hat{G}^{ss}_{\Lambda} = P_s\,\hat{G}^{ss}_{\Lambda}\,P_s$ and $[P_s, Q] = 0$. Thus $\hat{G}^{ss}_{\Lambda} \in \{Q\}'$. For each $X \in \mathsf{G}$, $[X,Q] = 0 \Rightarrow [X,P_s] = 0$, whence $[\hat{G}^{ss}_{\Lambda}, X] = 0$. Again $\deg(\hat{G}^{ss}) = (0,0)$ (Corollary 4.102), so $[\,\hat{G}^{ss}_{\Lambda},\, X\,]_{\mathrm{gr}} = [\,\hat{G}^{ss}_{\Lambda},\, X\,] = 0$. □

Proposition 4.115 (Central holosymmetry under flat, topological reduction)**.** *If* (C3) *of Definition 4.111 holds on a simply connected* U*, then for all* $x,x' \in U$*,* $[\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X(x,x')\,]_{\mathrm{gr}} = 0$ *for every channel block* $X \in \mathsf{G}$.

Proof. By Proposition 4.59, choose a gauge with $\mathcal{A} = 0$ on U, hence $\mathcal{U} = \mathbf{1}$ and holonomies are trivial. By the assumption in (4.34), $\hat{G}^{ss}_{\Lambda}(x,x') = c(x,x')\,\mathbf{1}$ in this gauge, hence it commutes with all blocks. Gauge covariance of the bracket (Lemma 4.106) then implies centrality holds in any gauge, i.e. for the covariant form $g(x)\,(c\,\mathbf{1})\,g(x')^{\dagger}$ as written in (4.34). □

Theorem 4.116 (Central (or approximately central) holosymmetry)**.** *Assume any one of* (C1), (C2)*, or* (C3) *in Definition 4.111. Then for all* $X \in \mathsf{G}$*,*

$$[\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X\,]_{\mathrm{gr}} = 0, \qquad [\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X\,] = 0,$$

where the second equality follows from $\deg(\hat{G}^{ss}_{\Lambda}) = (0,0)$ *and Lemma 4.95.*

If the corresponding hypothesis holds only approximately (e.g. the H*-representation in* (C1) *is nearly irreducible, or* (4.34) *holds up to a small scalar defect), then letting* δ *be as in Definition 4.112, we have the uniform bound*

$$\big\|[\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X\,]_{\mathrm{gr}}\big\| = \big\|[\,\hat{G}^{ss}_{\Lambda}(x,x'),\, X\,]\big\| \;\le\; \delta\,\|X\| \quad \textit{for all } X \in \mathsf{G}.$$

In the exact cases (C1)–(C3) *one has* $\delta = 0$.

Proof. Preliminaries. Fix endpoints (x, x'). By construction $\mathsf{G} = \mathrm{span}\{\hat{G}^{\alpha\beta}_{\Lambda}(x, x')\}_{\alpha,\beta\in\mathcal{I}} \subset \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is a graded $*$-algebra (Definition 4.103); in particular $\deg(\hat{G}^{ss}) = \deg(s) + \deg(s) = (0,1) + (0,1) = (0,0)$ (even) by Definition 4.94. Hence the graded bracket with $\hat{G}^{ss}$ coincides with the ordinary commutator: $[\,\hat{G}^{ss}, X\,]_{\mathrm{gr}} = [\,\hat{G}^{ss}, X\,]$ for all X (Corollary 4.102). Moreover, by gauge covariance of the graded structure, the vanishing of the bracket is gauge-invariant (Lemma 4.106 and Corollary 4.64); we may therefore work in any convenient gauge.

Case (C1): Group averaging / Schur. Let H act unitarily on the fibres at each locus and assume the holosymmetric selector is defined by averaging, $\hat{\mathcal{F}}_s(y) = \int_H U_y(h)\,\hat{\mathcal{F}}_0(y)\,U_y(h)^\dagger\,dh$ (Haar measure), so $\hat{\mathcal{F}}_s(y)$ is H-equivariant. Denote by $\mathrm{End}_H(\mathcal{H}_{\mathrm{em}}(y))$ the H-intertwiners at y. Then $\hat{\mathcal{F}}_s(y), \hat{\mathcal{F}}_s(y)^\dagger \in \mathrm{End}_H(\mathcal{H}_{\mathrm{em}}(y))$ by construction, and the channel

$$\hat{G}^{ss}_{\Lambda}(x, x') = \hat{\mathcal{F}}_s^\dagger(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_s(x') \qquad \text{(Definition 4.61)}$$

is an H-intertwiner from $\mathcal{H}_{\mathrm{em}}(x')$ to $\mathcal{H}_{\mathrm{em}}(x)$. Under the same symmetry, every block $\hat{G}^{\alpha\beta}_{\Lambda}(x, x')$ is also an H-intertwiner (selectors and transport are H-equivariant), so $\mathsf{G} \subset \mathrm{Hom}_H\Big(\mathcal{H}_{\mathrm{em}}(x'), \mathcal{H}_{\mathrm{em}}(x)\Big)$. Decompose both endpoint fibres into H-isotypic components. By the double-commutant/Schur decomposition, Hom_H is block-diagonal with scalar matrices on each multiplicity space; in particular, any two intertwiners commute on each isotypic block. Therefore $\hat{G}^{ss}_{\Lambda}$ commutes with every $X \in \mathsf{G}$, i.e. $[\,\hat{G}^{ss}_{\Lambda}, X\,] = 0$. In the irreducible case on the relevant subspace, Schur's lemma sharpens this to $\hat{G}^{ss}_{\Lambda} = c\,\Pi$ with $c \in \mathbb{C}$ and Π the intertwiner identity, which is manifestly central.

Case (C2): Superselection. Assume that label s determines a superselection charge and that the observable/channel algebra at fixed endpoints is the commutant of that charge, i.e. $\mathsf{G} \subset \mathcal{A}'$ for the charge representation, while $\hat{G}^{ss}_{\Lambda} \in Z(\mathcal{A}')$ by construction. Then $[\,\hat{G}^{ss}_{\Lambda}, X\,] = 0$ for all $X \in \mathsf{G}$ since central elements of the commutant commute with the whole commutant. (See Proposition 4.114 for a detailed realization.)

Case (C3): Flat, topological reduction. On a simply connected neighbourhood with $\mathcal{F} = 0$ (Proposition 4.59), choose a flat gauge so that $\mathcal{U}(x \leftarrow x'; \gamma) = g(x)\,g(x')^\dagger$ and holonomies are trivial. If s is defined as a gauge-invariant functional of holonomy classes, then in this flat gauge it reduces to an endpoint functional, yielding (for some scalar functions c_s) the reduction

$$\hat{G}^{ss}_{\Lambda}(x, x') = \; c_s(x)\,c_s(x')^*\,\mathbf{1}, \tag{4.35}$$

which clearly commutes with every $X \in \mathsf{G}$ (see Proposition 4.115 for the explicit reduction). By gauge covariance of the bracket (Lemma 4.106 and Corollary 4.64), commutation holds in all gauges.

Combining the three cases shows $[\,\hat{G}^{ss}_{\Lambda}, X\,] = 0$ for all $X \in \mathsf{G}$, hence $[\,\hat{G}^{ss}_{\Lambda}, X\,]_{\mathrm{gr}} = 0$ since $\hat{G}^{ss}$ is even.

Approximate statement. Suppose the hypotheses hold with defect ε. Typical instances: (i) in (C1), the H-averaging projects to an "almost irreducible" block so that on the regulated fibre $\|\hat{G}^{ss}_{\Lambda} - c\,\Pi\| \le \varepsilon$ for some scalar c; (ii) in (C3), flatness/holonomy reduction holds up to $\|\hat{G}^{ss}_{\Lambda} - c_s(x)c_s(x')^*\,\mathbf{1}\| \le \varepsilon$. For any $X \in \mathsf{G}$,

$$\|[\,\hat{G}^{ss}_{\Lambda}, X\,]\| = \|[\,(\hat{G}^{ss}_{\Lambda} - c\mathbf{1}) + c\mathbf{1},\, X\,]\| = \|[\,\hat{G}^{ss}_{\Lambda} - c\mathbf{1},\, X\,]\| \le 2\,\varepsilon\,\|X\|,$$

using bilinearity, $[c\mathbf{1}, X] = 0$, and the standard bound $\|AB - BA\| \le \|A\|\,\|B\| + \|B\|\,\|A\|$. Since $\hat{G}^{ss}$ is even, the same estimate holds for the graded bracket. The bound is uniform in X on norm-bounded subsets of G, completing the approximate centrality claim.

Conclusion. Under any of (C1)–(C3) we have $[\,\hat{G}^{ss}_{\Lambda},\, X\,]_{\mathrm{gr}} = 0$ for all $X \in \mathsf{G}$; under approximate hypotheses the commutator norm is uniformly $O(\varepsilon)$. This proves the theorem. □

Remark 4.117 (Operational meaning of central holosymmetry)**.** Theorem 4.116 asserts that the holosymmetric channel $\hat{G}^{ss}_{\Lambda}(x, x')$ is an *even, graded–central* element of the channel $*$-algebra G (Definitions 4.94 and 4.103): for every $X \in \mathsf{G}$, $[\,\hat{G}^{ss}_{\Lambda}, X\,]_{\mathrm{gr}} = 0$. Concretely:

(a) **No color mixing, only uniform weighting.** Since $\deg(\hat{G}^{ss}) = (0, 0)$, the graded bracket reduces to the ordinary commutator (Corollary 4.102). Thus $\hat{G}^{ss}_{\Lambda}$ preserves the $\mathbb{Z}_2^2$-grading of every channel (Proposition 4.99): it cannot create or annihilate dialectic "color''; it only rescales/phases existing amplitudes.

(b) **Order–insensitivity in compositions.** In any word of channels built by block composition through intermediate loci (Proposition 4.85), $\hat{G}^{ss}_{\Lambda}$ may be moved freely to the left or right without changing the value. Perturbatively, insertions of $\hat{G}^{ss}_{\Lambda}$ can be regrouped in Dyson/Neumann expansions with no effect on the sum, and with $O(\varepsilon)$ control in the approximate case of Theorem 4.116.

(c) **Gauge stability and endpoint interpretation.** Centrality is invariant under local gauge by the covariance of the graded structure (Lemma 4.106 and Corollary 4.64). In the flat, simply connected regime (Proposition 4.59), $\hat{G}^{ss}_{\Lambda}$ reduces to an endpoint scalar (or scalar multiple of the identity) (Proposition 4.115), so holosymmetric "phases'' can be pushed to the endpoints without altering any inter-modal coupling.

(d) **Compatibility with Twofold reductions.** Within the Twofold block (eq. (4.25)) and in the duality–collapse regime (Definition 4.87), centrality implies that $\hat{G}^{ss}_{\Lambda}$ acts as a scalar on the effective qubit sector; hence it does not obstruct the qubit recovery (Proposition 4.90).

(e) **Relation to symmetry mechanisms.** The three sufficient mechanisms in Definition 4.111 explain why centrality is natural: group averaging/Schur (C1) makes $\hat{G}^{ss}_{\Lambda}$ an intertwiner–scalar, superselection (C2) places it in the center of the commutant, and flat topological reduction (C3) collapses it to endpoint data. Each mechanism yields the same algebraic consequence in G.

In short, central (holosymmetric) structure *controls* amplitudes but does not *couple* dialectic sectors: it is globally present, gauge-stable, and algebraically inert with respect to graded commutation, so that physical predictions extracted from the Fourfold kernel (Section 4.1.2 and eq. (4.23)) are insensitive to the ordering of holosymmetric factors.

Remark 4.118 (Cross-chapter anchoring)**.** The ingredients used above are intrinsic to the developed formalism: (i) channel assembly and gauge covariance (Definition 4.61, Proposition 4.54, and Corollary 4.64), (ii) flatness ⇒ pure gauge transports (Proposition 4.59), and (iii) graded algebraic control of commutators (Definition 4.103, Proposition 4.104, and Lemma 4.106). When H encodes implementation symmetries of the holosymmetric interferometer (Chapter 3), (C1) matches the group-averaging constructions leading to implementation-invariant

effects; superselection scenarios (C2) arise naturally from the Chapter 1/2 mode-typing when charge sectors are fixed by preparation/measurement.

Postulate 4.2 (Graded nilpotency along the p–s edge)**.** *Certain colored transitions are graded-nilpotent, e.g.* $(\hat{G}^{ps})^2 = 0$ *and* $(\hat{G}^{sp})^2 = 0$*, capturing one-step synthesis/holothesis conversions that cannot pile up coherently in series.*

Definition 4.119 (Nilpotency hypotheses on the p–s edge)**.** Let $\mathsf{G} = \mathrm{span}\{\hat{G}^{\alpha\beta}_{\Lambda}(x,x')\}_{\alpha,\beta\in\mathcal{I}} \subset \mathcal{B}(\mathcal{H}_{\mathrm{em}})$ be the graded channel $*$-algebra of Definition 4.103, with degrees $\deg(\hat{G}^{\alpha\beta}) = \deg(\alpha) + \deg(\beta)$ as in Definition 4.94. We say that one of the following hypotheses holds.

(N1) Differential structure. There exists a graded differential d of degree $(1,1)$ on the mode complex (with $\mathsf{d}^2 = 0$) such that the functorial channel assignment $\Gamma : \mathrm{End}(\mathrm{Modes}) \to \mathsf{G}$ satisfies $\Gamma(\mathsf{d}) = \hat{G}^{ps}_{\Lambda}$ and is multiplicative with respect to composition, in the sense implemented by block composition through an intermediate locus $\big($cf. Proposition 4.85$\big)$.

(N2) Orthogonality at an intermediate locus. There exists a locus y (with dialectic completeness Definition 4.84) such that the p– and s–selectors have orthogonal supports,

$$\hat{\mathcal{F}}_s^{\dagger}(y)\,\hat{\mathcal{F}}_p(y) = 0 \quad = \quad \hat{\mathcal{F}}_p^{\dagger}(y)\,\hat{\mathcal{F}}_s(y), \tag{4.36}$$

and transports are unitary (Definition 4.48 and Lemma 4.50), so that orthogonality is preserved under insertion of resolutions at y.

(N3) Spectral selection rule (cutoff). With the spectral regulation $\mathrm{Ran}\, E^{(x)}([0,\lambda_{\mathrm{cutoff}}])$ from eq. (4.303), composing two $p\to s$ (or two $s\to p$) channels exits the regulated band, i.e.

$$E^{(x)}\hat{G}^{ps}_{\Lambda}(x,x')\big(\mathbf{1} - E^{(x')}\big) = \hat{G}^{ps}_{\Lambda}(x,x') \quad \text{and} \quad \big(\mathbf{1} - E^{(x)}\big)\hat{G}^{ps}_{\Lambda}(x,x')E^{(x')} = \hat{G}^{ps}_{\Lambda}(x,x'), \tag{4.37}$$

so that on the regulated fibres the square of $\hat{G}^{ps}_{\Lambda}$ (and similarly $\hat{G}^{sp}_{\Lambda}$) vanishes.

Proposition 4.120 (Nilpotent p–s edge under differential structure)**.** *If* (N1) *of Definition 4.119 holds, then* $(\hat{G}^{ps}_{\Lambda})^2 = 0$ *and* $(\hat{G}^{sp}_{\Lambda})^2 = 0$*.*

Proof. By hypothesis, $\hat{G}^{ps}_{\Lambda} = \Gamma(\mathsf{d})$ and Γ respects composition via the block composition identity of Proposition 4.85. Thus $(\hat{G}^{ps}_{\Lambda})^2 = \Gamma(\mathsf{d})\,\Gamma(\mathsf{d}) = \Gamma(\mathsf{d}^2) = \Gamma(0) = 0$. The same argument applies to $\hat{G}^{sp}_{\Lambda}$ when $\Gamma(\mathsf{d}^{\dagger}) = \hat{G}^{sp}_{\Lambda}$, using $\mathsf{d}^2 = 0$ and Lemma 4.66 for adjoints. □

Proposition 4.121 (Nilpotent p–s edge under orthogonality)**.** *If* (N2) *of Definition 4.119 holds, then* $(\hat{G}^{ps}_{\Lambda}(x,x'))^2 = 0$ *and* $(\hat{G}^{sp}_{\Lambda}(x,x'))^2 = 0$ *for all* x, x'*.*

Proof. Fix x, x' and insert the dialectically complete resolution at y (Definition 4.84) into the product $(\hat{G}^{ps})^2$ using the block composition rule (Proposition 4.85):

$$\hat{G}^{ps}(x,x')\,\hat{G}^{ps}(x,x') = \sum_{\gamma\in\mathcal{I}} \hat{G}^{p\gamma}(x,y)\,\hat{G}^{\gamma s}(y,x')\,\hat{G}^{ps}(x,x').$$

Expanding one more time through y and using the channel definition $\hat{G}^{\alpha\beta} = \hat{\mathcal{F}}_{\alpha}^{\dagger}\,\mathcal{U}\,\hat{\mathcal{F}}_{\beta}$ (Definition 4.61), every contribution contains at the locus y a factor of the form $\hat{\mathcal{F}}_s^{\dagger}(y)\hat{\mathcal{F}}_p(y)$ (or its adjoint) between two unitary transports. By (4.36) this factor is zero, and unitarity of transport (Lemma 4.50) preserves the orthogonality. Hence each summand vanishes and $(\hat{G}^{ps})^2 = 0$. The same argument, with p and s exchanged, yields $(\hat{G}^{sp})^2 = 0$. □

Proposition 4.122 (Nilpotent p–s edge under spectral selection)**.** *If* (N3) *of Definition 4.119 holds, then on the regulated fibres* $\operatorname{Ran} E^{(x)}([0,\lambda_{\text{cutoff}}])$ *one has* $(\hat{G}^{ps}_{\Lambda})^2 = 0$ *and* $(\hat{G}^{sp}_{\Lambda})^2 = 0$.

Proof. Let $\Pi_x := E^{(x)}([0,\lambda_{\text{cutoff}}])$. By (4.37), $\Pi_x \hat{G}^{ps}(x,x')\Pi_{x'} = 0$ while $\hat{G}^{ps}(x,x') = \Pi_x^{\perp}\hat{G}^{ps}(x,x')\Pi_{x'}^{\perp}$. Therefore

$$\Pi_x\,\hat{G}^{ps}(x,x')\,\Pi_{x'}\,\hat{G}^{ps}(x,x')\,\Pi_{x'} = \Big(\Pi_x\hat{G}^{ps}(x,x')\Pi_{x'}\Big)\Big(\hat{G}^{ps}(x,x')\Pi_{x'}\Big) = 0,$$

and similarly for all other placements of $\Pi/\Pi^{\perp}$ that restrict to the regulated fibres. Hence $(\hat{G}^{ps})^2 = 0$ on $\Pi\mathcal{H}_{\text{em}}$. The same argument applies to $\hat{G}^{sp}$. □

Theorem 4.123 (Nilpotent p–s edge under Y)**.** *Assume any one of* (N1), (N2), *or* (N3) *in Definition 4.119. Then*

$$(\hat{G}^{ps}_{\Lambda})^2 = (\hat{G}^{sp}_{\Lambda})^2 = 0.$$

Moreover, the degree constraint $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1,0)$ *(Definition 4.94) is consistent with nilpotency and with gauge covariance of products (Lemma 4.98).*

Proof. Preliminaries. For fixed endpoints (x,x'), recall $\hat{G}^{\alpha\beta}_{\Lambda}(x,x') = \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_{\beta}(x')$ (Definition 4.61). By the grading convention, $\deg(\hat{G}^{\alpha\beta}) = \deg(\alpha) + \deg(\beta)$ (Definition 4.94), hence

$$\begin{aligned}\deg(\hat{G}^{ps}) &= \deg(p) + \deg(s) = (1,1) + (0,1) = (1,0),\\ \deg(\hat{G}^{sp}) &= \deg(s) + \deg(p) = (0,1) + (1,1) = (1,0).\end{aligned} \tag{4.38}$$

and $\deg\Big((\hat{G}^{ps})^2\Big) = \deg\Big((\hat{G}^{sp})^2\Big) = (0,0)$. Degree additivity and gauge covariance under endpoint conjugation will be used repeatedly (Lemma 4.98, Corollary 4.64, and Proposition 4.54).

Square expansion and the "kill term". We compute

$$(\hat{G}^{ps}_{\Lambda})^2 = \hat{\mathcal{F}}^{\dagger}_{p}\,\mathcal{U}\,\hat{\mathcal{F}}_{s}\,\hat{\mathcal{F}}^{\dagger}_{p}\,\mathcal{U}\,\hat{\mathcal{F}}_{s} \tag{4.39}$$

$$= \hat{\mathcal{F}}^{\dagger}_{p}\,\mathcal{U}\,\underbrace{\big(\hat{\mathcal{F}}\,\hat{\mathcal{F}}^{\dagger}_{p}\big)}_{s}{}_{\text{kill term}}\,\mathcal{U}\,\hat{\mathcal{F}}_{s}. \tag{4.40}$$

Case (N1): Differential/typing structure on the p–s edge. By the domain/codomain *typing* of holosymmetric words (Remark 4.140 together with Proposition 4.85), the composition $\hat{\mathcal{F}}_s\hat{\mathcal{F}}^{\dagger}_p$ in (4.40) is ill-typed and hence vanishes under (N1). Therefore

$$\hat{\mathcal{F}}_s\hat{\mathcal{F}}^{\dagger}_p = 0 \quad\Longrightarrow\quad (\hat{G}^{ps}_{\Lambda})^2 = 0. \tag{4.41}$$

The $(\hat{G}^{sp}_{\Lambda})^2 = 0$ case is identical by swapping $p \leftrightarrow s$.

(Optional alternative under (N1)). Equivalently, if d is the graded differential on the two–node subcomplex $\{p,s\}$ with $\mathsf{d}^2 = 0$ and representation $\mathsf{d}|_{s\to p} \mapsto \hat{G}^{ps}_{\Lambda}$, $\mathsf{d}|_{p\to s} \mapsto \hat{G}^{sp}_{\Lambda}$, then functoriality yields $(\hat{G}^{ps}_{\Lambda})^2 = \rho((\mathsf{d}|_{s\to p})^2) = 0$ and likewise for sp.

Case (N2): Rank/orthogonality at an intermediate locus. Assume $\hat{\mathcal{F}}^{\dagger}_s(y)\hat{\mathcal{F}}_p(y) = 0$ at some intermediate locus y and that the selector family at y is dialectically complete (Definition 4.84). Using block composition through y (Proposition 4.85),

$$\hat{G}^{ps}_{\Lambda}(x,x') = \sum_{\gamma\in\mathcal{I}} \hat{G}^{p\gamma}_{\Lambda}(x,y)\,\hat{G}^{\gamma s}_{\Lambda}(y,x').$$

Hence

$$(\hat{G}^{ps}_{\Lambda})^2 = \sum_{\gamma,\delta} \hat{G}^{p\gamma}_{\Lambda}(x,y)\, \underbrace{\hat{G}^{\gamma s}_{\Lambda}(y,x')\, \hat{G}^{p\delta}_{\Lambda}(x,y)}_{\mathsf{M}_{\gamma\delta}}\, \hat{G}^{\delta s}_{\Lambda}(y,x').$$

Expanding $\mathsf{M}_{\gamma\delta}$ into selectors and transports, one finds that every term contains, at the locus y, a factor of the form $\hat{\mathcal{F}}^{\dagger}_{s}(y)\hat{\mathcal{F}}_{p}(y)$ or its adjoint, produced by the contraction of the γ- and δ-legs across y. By the orthogonality hypothesis this vanishes, whence $\mathsf{M}_{\gamma\delta} = 0$ for all γ, δ, and therefore $(\hat{G}^{ps}_{\Lambda})^2 = 0$. The same argument with $p \leftrightarrow s$ yields $(\hat{G}^{sp}_{\Lambda})^2 = 0$. Degree additivity and gauge covariance are preserved termwise (Lemma 4.98), so the conclusion is gauge-invariant.

Case (N3): Spectral cutoff / support exit. Let $E^{(y)}([0, \lambda_{\text{cutoff}}])$ be the spectral projector defining the regulated fibre at y (eq. (4.303)). Suppose the realizations are arranged so that a $p \to s$ map lands outside the admissible band for a subsequent $p \to s$ application (support–exit selection rule in Definition 4.119(N3)). Insert the resolution of the identity at y, $\mathbf{1} = E^{(y)} + [I - E^{(y)}]$, between the two factors of $\hat{G}^{ps}_{\Lambda}$. By hypothesis the image of the first $p \to s$ step lies in $\mathrm{Ran}(I - E^{(y)})$, while the second $p \to s$ factor has domain restricted to $\mathrm{Ran}(E^{(y)})$; hence their composition vanishes on the regulated fibre, and $(\hat{G}^{ps}_{\Lambda})^2 = 0$. The same holds for $s \to p$. Since endpoint conjugation preserves spectral bands and zero operators (Proposition 4.54 and Corollary 4.64), the statement is gauge-stable. Degree additivity remains as above.

Degree/gauge consistency. In all cases, $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1,0)$ by construction (Definition 4.94), and products transform covariantly under gauge with unchanged degree (Lemma 4.98). The vanishing of a product is preserved under unitary conjugation, so nilpotency holds in any gauge.

Conclusion. Under any one of (N1)–(N3), both $(\hat{G}^{ps}_{\Lambda})^2$ and $(\hat{G}^{sp}_{\Lambda})^2$ vanish, with grading and gauge properties consistent with Definition 4.94 and Lemma 4.98. □

Remark 4.124 (Operational meaning of a nilpotent p–s edge)**.** Theorem 4.123 states that the $p \leftrightarrow s$ converters behave as *odd, square–zero* morphisms in the channel algebra: $(\hat{G}^{ps}_{\Lambda})^2 = (\hat{G}^{sp}_{\Lambda})^2 = 0$ with $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1,0)$ (Definition 4.94). Concretely:

(a) **One–step conversion only.** Any word containing two successive $p \to s$ (or $s \to p$) factors collapses to zero. Hence series over the p–s edge *truncate at first order* (Corollary 4.125); higher multiple–conversion histories do not contribute.

(b) **Graded selection and interference.** The $(1,0)$ color of the edge maps fits the $\mathbb{Z}_2^2$ calculus of Definition 4.103 and eq. (4.30) and the blockwise selection rules in Proposition 4.99. In particular, graded commutators with $(0,1)$-colored channels pick up the expected sign, but the *squares* vanish identically, so there is no coherent stacking of $p \leftrightarrow s$ transitions.

(c) **Composed transport is simplified.** In block compositions through an intermediate locus (Proposition 4.85), any term that attempts a two–step $p \to s \to s$ or $s \to p \to p$ conversion vanishes termwise. Perturbative (Dyson/Neumann) expansions therefore have strictly fewer nonzero diagrams along the p–s edge.

(d) **Gauge stability.** Nilpotency and color are preserved by endpoint conjugation (Lemma 4.98, Corollary 4.64, and Proposition 4.54); thus the statement is *gauge–invariant* and holds in any local frame.

(e) **Compatibility with central holosymmetry.** When $\hat{G}^{ss}_\Lambda$ is central (Theorem 4.116), the $\{p, s\}$ subblock is (graded) upper–triangular with a nilpotent off–diagonal: ordering with $\hat{G}^{ss}_\Lambda$ is immaterial, and no iterative $p \leftrightarrow s$ cycling can build up.

(f) **Twofold reductions unaffected.** Because the edge is nilpotent, projecting to the Twofold sector ($\{0, 1\}$) does not acquire hidden higher–order contributions from p, s-loops; this supports the qubit recovery in the duality–collapse regime (Proposition 4.90).

In summary, a nilpotent p–s edge means *single–pass synthesis/holothesis conversion* with no iterative coherence. It is consistent with the graded algebraic structure, stable under gauge, and it reduces the combinatorics of channel compositions without constraining the Twofold slice.

Corollary 4.125 (Series truncation along the p–s edge)**.** *Assume the p–s nilpotency of Theorem 4.123, i.e. $(\hat{G}^{ps}_\Lambda)^2 = (\hat{G}^{sp}_\Lambda)^2 = 0$.*

(a) Pruning of nonalternating words

Every monomial in $\{\hat{G}^{ps}_\Lambda, \hat{G}^{sp}_\Lambda\}$ that contains $(\hat{G}^{ps}_\Lambda)^2$ or $(\hat{G}^{sp}_\Lambda)^2$ as a contiguous subword vanishes. Hence, in Dyson/Neumann or block–composition expansions (Proposition 4.85) all terms with two successive $p \to s$ or two successive $s \to p$ steps vanish termwise. Only strictly alternating *subwords (e.g. $\hat{G}^{ps}\hat{G}^{sp}\hat{G}^{ps}\cdots$) can survive.*

(b) Strong truncation under orthogonality and local flatness (optional)

If, in addition, the dialectic family is complete at each inserted intermediate locus (Definition 4.84), the p– and s–selectors are orthogonal there ($\hat{\mathcal{F}}_s^\dagger \hat{\mathcal{F}}_p = 0 = \hat{\mathcal{F}}_p^\dagger \hat{\mathcal{F}}_s$, Definition 4.119 (N2)), and transport is locally flat (so path-ordered transport reduces to endpoint conjugation, Propositions 4.54 and 4.59), then any surviving (alternating) word reduces to a linear combination of $\mathbf{1}$, $\hat{G}^{ps}_\Lambda$, and $\hat{G}^{sp}_\Lambda$.

Proof. (a) Let W be any word in the alphabet $\{E, F\} := \{\hat{G}^{ps}_\Lambda, \hat{G}^{sp}_\Lambda\}$. If W contains EE or FF contiguously, then by Theorem 4.123 the corresponding factor equals 0, so the entire monomial vanishes. In Dyson/Neumann or block–composition series (Proposition 4.85) the terms are ordered products of channels; the same cancellation applies termwise. Thus only strictly alternating subwords can contribute.

(b) Under Definition 4.84, insert the resolution at each intermediate locus y to factor alternating products via $\hat{G}^{\alpha\beta}(x, x') = \sum_{\gamma\in\mathcal{I}} \hat{G}^{\alpha\gamma}(x, y)\hat{G}^{\gamma\beta}(y, x')$ (Proposition 4.85). For an alternating pair, e.g. $\hat{G}^{ps}(x, y)\hat{G}^{sp}(y, x')$, the definition $\hat{G}^{\alpha\beta} = \hat{\mathcal{F}}^\dagger_\alpha \mathcal{U}\, \hat{\mathcal{F}}_\beta$ (Definition 4.61) gives

$$\hat{G}^{ps}(x, y)\hat{G}^{sp}(y, x') = \hat{\mathcal{F}}^\dagger_p(x)\,\mathcal{U}(x \leftarrow y)\, \underbrace{\hat{\mathcal{F}}_s(y)\hat{\mathcal{F}}^\dagger_s(y)}_{=:P_s(y)}\, \mathcal{U}(y \leftarrow x')\, \hat{\mathcal{F}}_p(x').$$

Orthogonality $(N2)$ implies $P_s(y)$ is a projection orthogonal to the p-support ($\hat{\mathcal{F}}_s^\dagger \hat{\mathcal{F}}_p = 0$), and unitarity of transport preserves these supports (Lemma 4.50). Under local flatness (Proposition 4.59) we may gauge-fix so that transports collapse to endpoint conjugations, whence $P_s(y)$ can be moved to an endpoint and absorbed into a diagonal factor that either acts as the identity on its support or is zero. Iterating this reduction shows that any alternating word collapses to a linear combination of $\mathbf{1}$, $\hat{G}^{ps}$, and $\hat{G}^{sp}$. Gauge covariance of the reduction follows from Corollary 4.64 and Lemma 4.106. □

Remark 4.126 (Cross-chapter anchoring and interpretation)**.** *Differential view (N1).* In Chapter 1 the tetralemma modes carry algebraic operations; modeling $p \leftrightarrow s$ as a graded differential d matches the $\mathbb{Z}_2^2$-grading of Definition 4.94 and promotes $\hat{G}^{ps}$ to a "boundary" map whose square vanishes. *Orthogonality view (N2).* If the parasymmetric and holosymmetric selectors are realized as partial isometries onto orthogonal subspaces at an intermediate locus, then the block-composition identity (Proposition 4.85) forces two-step $p \to s \to s$ (and $s \to p \to p$) processes to vanish. *Spectral view (N3).* In Chapter 2/3 implementations with spectral windows (eq. (4.303)), certain cross-mode transitions leave the energy band; restricting to the regulated fibre yields algebraic nilpotency of the corresponding channel squares.

Postulate 4.3 (Bosonic compatibility in the 0–s sector)**.** *Even channels generated by symmetry and holosymmetry diagonals commute:* $[\hat{G}^{00}, \hat{G}^{ss}] = 0$*, and more generally* $[\hat{G}^{00}, \hat{X}]_{\mathrm{gr}} = [\hat{G}^{00}, \hat{X}]$ *(no color flips).*

Definition 4.127 (Bosonic-commutation hypotheses in the 0–s sector)**.** Let

$$\mathsf{G} := \operatorname{span}\left\{ \hat{G}^{\alpha\beta}_{\Lambda}(x,x') \;\middle|\; \alpha,\beta \in \mathcal{I} \right\} \subset \mathcal{B}\big(\mathcal{H}_{\mathrm{em}}\big)$$

be the graded channel $*$-algebra of Definition 4.103, with degrees as in Definition 4.94. We consider the following sufficient hypotheses for the commutation

$$\Big[\hat{G}^{00}_{\Lambda}(x,x'),\, \hat{G}^{ss}_{\Lambda}(x,x')\Big] = 0$$

(hence also $\Big[\hat{G}^{00}_{\Lambda},\, \hat{G}^{ss}_{\Lambda}\Big]_{\mathrm{gr}} = 0$, since diagonals are even by Corollary 4.102).

(B1) Shared spectral functional. There exists a self-adjoint observable $Z(x,x')$ (gauge-invariant under Corollary 4.64) such that both diagonal channels are Borel functions of Z on the regulated fibre $\operatorname{Ran} E^{(x)}([0,\lambda_{\mathrm{cutoff}}])$ (cf. eq. (4.303)):

$$\hat{G}^{00}_{\Lambda}(x,x') = f\Big(Z(x,x')\Big), \qquad \hat{G}^{ss}_{\Lambda}(x,x') = g\Big(Z(x,x')\Big).$$

(B2) Central holosymmetry. The holosymmetric diagonal is central in G, e.g. under any of the hypotheses (C1)–(C3) of Definition 4.111 (see Theorem 4.116).

(B3) Joint unitary diagonalizability. On the regulated fibre, $\hat{G}^{00}_{\Lambda}(x,x')$ and $\hat{G}^{ss}_{\Lambda}(x,x')$ are normal and there exists a unitary W (possibly obtained in a flat gauge, cf. Propositions 4.54 and 4.59) such that $W^{\dagger}\hat{G}^{00}_{\Lambda}W = \operatorname{diag}(\lambda_i)$ and $W^{\dagger}\hat{G}^{ss}_{\Lambda}W = \operatorname{diag}(\mu_i)$.

Proposition 4.128 (Commutation from shared functional calculus)**.** *If* (B1) *of Definition 4.127 holds, then* $[\hat{G}^{00}_{\Lambda}(x,x'), \hat{G}^{ss}_{\Lambda}(x,x')] = 0$.

Proof. By the spectral theorem, Borel functions of the same self-adjoint operator commute: $[f(Z), g(Z)] = 0$. Since both diagonals are even-degree blocks (Corollary 4.102), the graded bracket coincides with the ordinary one. Gauge covariance of Z follows from Corollary 4.64, hence the statement is representation-independent. □

Proposition 4.129 (Commutation from central holosymmetry)**.** *If* (B2) *of Definition 4.127 holds, then* $[\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}] = 0$.

Proof. Centrality (e.g. from Theorem 4.116) gives $[\hat{G}^{ss}_\Lambda, X]_{\mathrm{gr}} = 0$ for all $X \in \mathsf{G}$; in particular with $X = \hat{G}^{00}_\Lambda$. Since both are even, the graded and ordinary commutators coincide. □

Proposition 4.130 (Commutation from joint diagonalizability)**.** *If* (B3) *of Definition 4.127 holds, then* $[\hat{G}^{00}_\Lambda(x,x'), \hat{G}^{ss}_\Lambda(x,x')] = 0$.

Proof. Normal operators that are simultaneously unitarily diagonalizable commute. Hence

$$W^\dagger\,[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda]\,W = [\mathrm{diag}(\lambda_i), \mathrm{diag}(\mu_i)] = 0.$$

If the joint diagonalization is obtained in a flat gauge (Proposition 4.59), commutation holds in that gauge and thus in any gauge by covariance of the bracket (Lemma 4.106). □

Theorem 4.131 (Bosonic compatibility in the 0–*s* sector under Z)**.** *Assume any one of* (B1), (B2), *or* (B3) *in Definition 4.127. Then for all* x, x',

$$[\hat{G}^{00}_\Lambda(x,x'), \hat{G}^{ss}_\Lambda(x,x')] = 0, \qquad [\hat{G}^{00}_\Lambda(x,x'), \hat{G}^{ss}_\Lambda(x,x')]_{\mathrm{gr}} = 0.$$

The conclusion is stable under endpoint conjugation $X \mapsto g(x)\,X\,g(x')^\dagger$ *by Corollary 4.64 and Lemma 4.106.*

Corollary 4.132 (Even-sector control of 0–*s* dynamics)**.** *Assume the hypotheses of Theorem 4.131 (any of* (B1)–(B3) *in Definition 4.127), so that* $[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda] = 0$. *Then:*

(a) Degree-0 derivation (no color flips)
For every channel $X \in \mathsf{G}$ *supported on the* 0–*s sector,* $[\hat{G}^{00}_\Lambda, X]_{\mathrm{gr}} = [\hat{G}^{00}_\Lambda, X]$, *and* $\mathrm{ad}_{\hat{G}^{00}_\Lambda}$ *acts as a degree-*0 *derivation on that sector.*

(b) Endpoint gauging of even phases
If, in addition, (B3) *holds (joint unitary diagonalizability; cf. Proposition 4.130) or flatness holds on a simply connected neighbourhood (Proposition 4.59), then phases generated by* $\hat{G}^{00}_\Lambda$ *can be pushed to the endpoints by a gauge change: for any* $\theta \in \mathbb{R}$, *conjugations by* $e^{i\theta\hat{G}^{00}_\Lambda}$ *on* 0–*s channels are realized by endpoint unitaries via Corollary 4.64, leaving holosymmetric couplings unchanged.*

Proof. (a) Diagonal blocks are even by Corollary 4.102, hence for any X the graded bracket with $\hat{G}^{00}_\Lambda$ equals the ordinary commutator: $[\hat{G}^{00}_\Lambda, X]_{\mathrm{gr}} = [\hat{G}^{00}_\Lambda, X]$. Since G is an associative $*$-algebra (Definition 4.103), $\mathrm{ad}_{\hat{G}^{00}_\Lambda}$ is a derivation. Restricted to the 0–*s* sector, degrees are preserved (no color flips) by Lemma 4.98 and Proposition 4.99(a–b). (b) Under $[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda] = 0$ (Theorem 4.131), functional calculus gives $e^{i\theta\hat{G}^{00}_\Lambda}\hat{G}^{ss}_\Lambda = \hat{G}^{ss}_\Lambda e^{i\theta\hat{G}^{00}_\Lambda}$. With (B3) or flatness, we may simultaneously diagonalize (or reduce transport to endpoint conjugation), so conjugation by $e^{i\theta\hat{G}^{00}_\Lambda}$ can be implemented as an endpoint gauge $X \mapsto g(x)\,X\,g(x')^\dagger$ (Proposition 4.54 and Corollary 4.64), which does not alter holosymmetric couplings; invariance of the graded structure under such conjugations is Lemma 4.106. □

Remark 4.133 (Interpretation and cross-chapter links)**.** Even-sector diagonals $\hat{G}^{00}$ (local symmetry persistence) and $\hat{G}^{ss}$ (holosymmetric persistence) behave "bosonically": their mutual commutation means that self-persistence amplitudes in the symmetry and holosymmetry channels can be simultaneously resolved without color mixing. Under flatness (Proposition 4.59)

and the holosymmetric constructions of Chapter 3 (eqs. (3.35) and (3.36)), this translates to a common eigenbasis for endpoint observables controlling local symmetry and global invariants, so that the corresponding effects can be measured compatibly. In Chapter 1's selector formalism, this compatibility matches the even-degree structure (Definition 4.94 and Corollary 4.102) and sits naturally inside the graded Lie $*$-algebra of channels (Proposition 4.104 and Lemma 4.106).

Graded covariant kinematics (along a path)

Let $\mathcal{A} \in \Omega^1(\mathcal{X}_q, \mathfrak{u}(\mathcal{H}_{\mathrm{em}}))$ be the (skew–Hermitian) connection entering the transporter $\mathcal{U} = \mathcal{P}\exp\!\left(-\int_\gamma \mathcal{A}\right)$ (Definitions 4.48 and 4.49). Write $\mathcal{A} = \mathcal{A}_\mu\, dx^\mu$ in local coordinates near the endpoint x. Throughout, the graded bracket $[\cdot,\cdot]_{\mathrm{gr}}$ is that of Section 4.1.7 and eq. (4.30), and degrees are as in Definition 4.94.

Definition 4.134 (Graded covariant derivative on channel blocks)**.** For each component $\hat{G}^{\alpha\beta} = \hat{G}^{\alpha\beta}_\Lambda(x,x')$ (Definition 4.61), define

$$\mathfrak{D}_\mu \hat{G}^{\alpha\beta} := \partial_\mu \hat{G}^{\alpha\beta} + [\,\mathcal{A}_\mu, \hat{G}^{\alpha\beta}\,]_{\mathrm{gr}}. \tag{4.42}$$

Here ∂_μ differentiates with respect to the first endpoint x (holding x' fixed).

Lemma 4.135 (Gauge covariance and degree preservation)**.** *Under $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$,*

$$\mathcal{A}_\mu \mapsto \mathcal{A}'_\mu = g\,\mathcal{A}_\mu\, g^\dagger + (\partial_\mu g)\, g^\dagger, \qquad \hat{G}^{\alpha\beta}(x,x') \mapsto \hat{G}^{\alpha\beta\prime}(x,x') = g(x)\,\hat{G}^{\alpha\beta}(x,x')\,g(x')^\dagger$$

(Proposition 4.54 and Corollary 4.64), and

$$\mathfrak{D}'_\mu \hat{G}^{\alpha\beta\prime} = g(x)\left(\mathfrak{D}_\mu \hat{G}^{\alpha\beta}\right) g(x')^\dagger.$$

Moreover $\deg(\mathfrak{D}_\mu \hat{G}^{\alpha\beta}) = \deg(\hat{G}^{\alpha\beta})$ *since* $\deg(\mathcal{A}_\mu) = (0,0)$ *and the graded bracket preserves degree (Lemma 4.98).*

Proof. Direct computation with the stated gauge laws and bilinearity of $[\cdot,\cdot]_{\mathrm{gr}}$; degree preservation uses that even elements act without changing color and $\deg[X,Y]_{\mathrm{gr}} = \deg X + \deg Y$ (Section 4.1.7 and Lemma 4.98). □

Lemma 4.136 (Graded Leibniz rule)**.** *For channel-valued operators X, Y (with well-defined degrees), $\mathfrak{D}_\mu(XY) = (\mathfrak{D}_\mu X)Y + X(\mathfrak{D}_\mu Y)$.*

Proof. Expand $\partial_\mu(XY)$ and use $[\,\mathcal{A}_\mu, XY\,]_{\mathrm{gr}} = [\,\mathcal{A}_\mu, X\,]_{\mathrm{gr}}\, Y + X\,[\,\mathcal{A}_\mu, Y\,]_{\mathrm{gr}}$, which holds because $\deg(\mathcal{A}_\mu) = (0,0)$ (even). □

Proposition 4.137 (Parallel consistency along a path)**.** *Let $\gamma : [s_0, s_1] \to \mathcal{X}_q$ be C^1 with $\gamma(s_0) = x'$, $\gamma(s_1) = x$. Along γ, set $D_s := \partial_s + [A_\gamma(s), \cdot\,]_{\mathrm{gr}}$ with $A_\gamma(s) = (\gamma^*\mathcal{A})_s(\dot\gamma(s))$ (eq. (4.10)). Assume the endpoint selectors are* covariantly rigid *along γ at the readout end, i.e. $\partial_s \hat{\mathcal{F}}^\dagger_\alpha(\gamma(s)) + [A_\gamma(s), \hat{\mathcal{F}}^\dagger_\alpha(\gamma(s))] = 0$. Then for $\hat{G}^{\alpha\beta}(\gamma(s), x') = \hat{\mathcal{F}}^\dagger_\alpha(\gamma(s))\,\mathcal{U}(\gamma(s) \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x')$ one has*

$$D_s \hat{G}^{\alpha\beta}(\gamma(s), x') = 0.$$

Proof. Differentiate the defining product and use the ODE for transport $\partial_s \mathcal{U} = -A_\gamma(s)\mathcal{U}$ (Definition 4.49 and eq. (4.12)), the rigidity hypothesis at the left endpoint, and $[A_\gamma, \cdot]_{\mathrm{gr}}$ acting by derivations (Lemma 4.136). Terms cancel pairwise, yielding $D_s \hat{G}^{\alpha\beta} = 0$. □

Proposition 4.138 (Curvature identity)**.** *For any channel-valued X,*

$$[\mathfrak{D}_\mu, \mathfrak{D}_\nu]_{\mathrm{gr}} X = \Big[\, \mathcal{F}_{\mu\nu},\, X \,\Big]_{\mathrm{gr}}, \qquad \mathcal{F}_{\mu\nu} := \partial_\mu \mathcal{A}_\nu - \partial_\nu \mathcal{A}_\mu + [\mathcal{A}_\mu, \mathcal{A}_\nu]$$

($\mathcal{F}$ as in Definition 4.56). Consequently, if $\mathcal{F} = 0$ on a simply connected neighbourhood, $[\mathfrak{D}_\mu, \mathfrak{D}_\nu]_{\mathrm{gr}} = 0$ and parallel consistency integrates to path–independence up to endpoint gauge (Proposition 4.59 and Corollary 4.57).

Proof. Standard computation using (4.42) and evenness of $\mathcal{A}_\mu$. Gauge covariance of both sides follows from Lemma 4.135; the flat case follows by integrability and Proposition 4.59. □

Remark 4.139 (Kinematic reading)**.** Equation (4.42) is a bookkeeping device for endpoint–wise variations of channel blocks. Under the pointwise realization $\hat{G}^{\alpha\beta}(x, x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\hat{\mathcal{F}}_\beta(x')$, the constraint $\mathfrak{D}_\mu \hat{\mathbf{G}}_\Lambda = 0$ enforces *parallel consistency* between preparation, transport, and readout, while $\mathcal{F} \neq 0$ sources deviations via Proposition 4.138, i.e. holonomy-induced effects (Definition 4.56 and eq. (4.18)). Degree preservation and gauge covariance are guaranteed by Lemmas 4.98 and 4.135.

Why the graded algebra is necessary

A *graded* algebra is the minimal, precise device that records (i) which channels are allowed to mix, (ii) how they compose, and (iii) which sign/phase rules govern their couplings—while remaining faithful to the tetralemma's four facets, to gauge covariance of transport, and to the Hermitian/operator character of the correlator. An ungraded matrix algebra would blur these distinctions and admit spurious couplings that violate the logical architecture fixed by the selector–transport formalism (Definition 4.61, Proposition 4.54, and Corollary 4.64).

Dialectic colors and additivity. Structurally, the four modes $\{0, 1, p, s\}$ encode two independent oppositions—the dyad $0 \leftrightarrow 1$ and the global/implementation axis $0 \leftrightarrow s$—with p behaving as their composite. The $\mathbb{Z}_2 \times \mathbb{Z}_2$ grading formalizes this (Definition 4.94):

$$\deg(0) = (0,0), \qquad \deg(1) = (1,0), \qquad \deg(s) = (0,1), \qquad \deg(p) = (1,1).$$

Channel components inherit color additively,

$$\deg\big(\hat{G}^{\alpha\beta}\big) = \deg(\alpha) + \deg(\beta),$$

so composition preserves color and block structure (cf. Proposition 4.99).

The graded bracket encodes selection rules. The graded (color) bracket of Section 4.1.7 and eq. (4.30)

$$[X, Y]_{\mathrm{gr}} := XY - (-1)^{\langle \deg X, \deg Y \rangle} YX, \qquad \langle (a_1, a_2), (b_1, b_2) \rangle := a_1 b_1 + a_2 b_2 \pmod 2,$$

derives the interference/transition rules instead of imposing them by hand:

- If either factor is even $(0,0)$ (e.g. any diagonal $\hat{G}^{\alpha\alpha}$ by Corollary 4.102), one gets the ordinary commutator.
- Same nontrivial color may commute or anticommute depending on the color: two $(1,0)$ or two $(0,1)$ components *anticommute* (the bilinear form gives 1), whereas two $(1,1)$ components *commute* (the bilinear form gives 0).
- Mixed colors follow the sign dictated by $\langle \deg X, \deg Y \rangle$: e.g. $(1,0)$ with $(0,1)$ commute (dot $= 0$), while $(1,0)$ with $(1,1)$ anticommute (dot $= 1$).

These sign rules are exactly what keeps Synthesis p and Holothesis s distinct yet composable with the dyad $\{0,1\}$ (see the block patterns in Proposition 4.99).

Hermiticity and gauge covariance are respected. Hermitian symmetry $(\hat{G}^{\alpha\beta})^\dagger = \hat{G}^{\beta\alpha}$ preserves degree (Lemma 4.66 and Corollary 4.102), and the unitary gauge action

$$\hat{G}^{\alpha\beta}(x,x') \;\mapsto\; g(x)\,\hat{G}^{\alpha\beta}(x,x')\,g(x')^\dagger$$

(Proposition 4.54 and Corollary 4.64) leaves product, adjoint, colors, and the bracket intact (Lemma 4.98). Thus the graded $*$-algebra is *gauge–covariant*, as required when channels are defined via the transporter $\mathcal{U}$ (Definition 4.48).

Even core acting by derivations. The grading separates *self-persistence* from *mode-changing* in a controlled way: the even subalgebra generated by $\{\hat{G}^{\alpha\alpha}\}$ acts by (graded) derivations on each colored off-diagonal class, without forcing color flips; see Section 4.1.7 and the derivation property of the graded bracket in Section 4.1.7.

Kinematics that match geometry. The unique degree-preserving, gauge-covariant coupling to the connection $\mathcal{A}$ is the graded covariant derivative

$$\mathfrak{D}_\mu \hat{G}^{\alpha\beta} = \partial_\mu \hat{G}^{\alpha\beta} + [\mathcal{A}_\mu, \hat{G}^{\alpha\beta}]_{\mathrm{gr}},$$

(Definition 4.134), which ensures parallel consistency and locates holonomy effects in the *correct* sectors in accord with the transporter's geometry (Definition 4.56 and Propositions 4.59 and 4.138).

Bottom line. The $\mathbb{Z}_2 \times \mathbb{Z}_2$ graded $*$-algebra is not ornamentation. It is the minimal structure that (i) respects the dual–dual (dyad $\times$ global) nature of the four modes, (ii) enforces the correct selection rules and signs in compositions, (iii) preserves Hermiticity and gauge covariance, and (iv) provides a clean, covariant template for kinematics. Without grading, one either loses these guarantees or must re-impose them piecemeal (cf. Section 4.1.7 for model assumptions that the graded framework cleanly supports).

4.2 Holosymmetric Words in Channel Algebra

Words as resolved histories. A *word* is an ordered product that spells out a channel at a chosen "temporal" resolution: selectors at the endpoints and parallel transporters (and, when present, device evolutions) in between. Concretely, for a chain of piecewise C^1 paths $\gamma_1 : x' \to x_1, \dots, \gamma_n : x_{n-1} \to x$,

$$W^{\alpha\beta}[\gamma_n, \dots, \gamma_1] := \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x_{n-1}; \gamma_n) \cdots \mathcal{U}(x_1 \leftarrow x'; \gamma_1)\, \hat{\mathcal{F}}_\beta(x').$$

By functoriality and inversion of transport (Proposition 4.52 and eq. (4.14)), this collapses to the single–channel form of Definition 4.61:

$$W^{\alpha\beta}[\gamma_n, \dots, \gamma_1] = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}\Big(x \leftarrow x';\, \gamma_n \circ \cdots \circ \gamma_1\Big)\, \hat{\mathcal{F}}_\beta(x') = \hat{G}^{\alpha\beta}_\Lambda(x, x').$$

Thus a word is the same channel seen at a finer "path resolution"; words multiply by concatenating paths and composing the corresponding operators.

Remark 4.140 (Typing and spectral domain)**.** Words are only formed when *typing constraints* match: the terminal mode/locus of one letter equals the initial mode/locus of the next (cf. Proposition 4.85 for insertion of completeness at intermediate loci). All operators act on the spectrally regulated fibres $\operatorname{Ran} E^{(x)}([0, \lambda_{\text{cutoff}}])$ (see eq. (4.303)), ensuring strong continuity of $\mathcal{U}$ along any piecewise C^1 path (Definitions 4.48 and 4.49).

Endpoint covariance and frame consistency. Selectors originate in Chapter 1, and the transporter is the gauge–covariant parallel transport of Definitions 4.48 and 4.49. Under a local gauge, selectors and transport transform as in Proposition 4.54 and Corollary 4.64. Interior gauge factors cancel along the product, so any word transforms by conjugation at its *endpoints* x, x'. This is precisely the operational role of words: frame–align the modal data along the path via $\mathcal{U}$, then read off with $\hat{\mathcal{F}}^\dagger_\alpha$ and $\hat{\mathcal{F}}_\beta$ in a way that is covariant at the endpoints.

Restriction to the Twofold sector and duality collapse. Restricting indices to $\alpha, \beta \in \{0, 1\}$ places words in the Twofold block $\hat{\mathbf{G}}_{(0,1)}(x, x')$ (eq. (4.25)). In the duality–collapse regime (Definition 4.87), off–block expectations vanish and the coincident–limit inner product induced by the Fourfold reduces to a bona fide qubit inner product on the Twofold fibre; operational predictions of all Twofold words then coincide with ordinary two–level kinematics (Proposition 4.90). Outside this regime, words that touch p or s diagnose coherent composition and global/implementation–invariant structure beyond the dyad.

Holosymmetric mechanisms as words. Chapter 3 realises holosymmetric comparisons by composing preparation, control, and readout unitaries (e.g. $\mathbf{U}_{\text{ctrl}}$ and its Hadamard conjugate, Definition 2.114 and eqs. (2.75) and (2.78)), acting on dual PQS registers (Definition 2.101). These mechanism–level composites are words at the device layer. When sandwiched by $\hat{\mathcal{F}}^\dagger_\alpha(\cdot)$ and $\hat{\mathcal{F}}_\beta(\cdot)$ and, if needed, a geometric $\mathcal{U}$, they produce the corresponding *holosymmetric channel words* whose expectations yield the holosymmetric effects (eq. (3.35)).

Behavior under flatness and path refinement. On simply connected regions with $\mathcal{F} = 0$ (Definition 4.56), path–ordered transport is path independent up to an endpoint gauge (Proposition 4.59); words that differ only by a refinement or wiggling of intermediate segments coincide after endpoint conjugation. Conversely, nonzero curvature produces holonomy (eq. (4.18)), and words expose this through the dependence on the concatenated path.

Graded bookkeeping for words. With the $\mathbb{Z}_2^2$ dialectic grading of Definition 4.94, a word inherits degree additively from its channel pieces; adjoint, gauge covariance, and composition are compatible with degree (Lemma 4.98). This graded bookkeeping governs selection rules and block patterns (Proposition 4.99) and underlies the graded Lie $*$-algebra structure introduced in Section 4.1.7.

Definition 4.141 (Holosymmetric channel alphabet and words)**.** Fix loci $x_0, \dots, x_n \in \mathcal{X}_q$ and $\mathcal{I} = \{0, 1, p, s\}$. The *channel alphabet* consists of all typed letters

$$\mathsf{L} \;:=\; \Big\{\, \hat{G}_\Lambda^{\alpha\beta}(x_j, x_{j-1}) \;:\; \alpha, \beta \in \mathcal{I},\; j = 1, \dots, n \,\Big\},$$

where each letter is the Fourfold channel block of Definition 4.61: $\hat{G}_\Lambda^{\alpha\beta}(x_j, x_{j-1}) = \hat{\mathcal{F}}_\alpha^\dagger(x_j)\, \mathcal{U}(x_j \leftarrow x_{j-1}; \gamma_j)\, \hat{\mathcal{F}}_\beta(x_{j-1})$, with $\mathcal{U}$ as in Definitions 4.48 and 4.49.

A *(channel) word* is a finite product

$$W \;:=\; \hat{G}_\Lambda^{\alpha_n \alpha_{n-1}}(x_n, x_{n-1})\, \hat{G}_\Lambda^{\alpha_{n-1} \alpha_{n-2}}(x_{n-1}, x_{n-2}) \cdots \hat{G}_\Lambda^{\alpha_1 \alpha_0}(x_1, x_0),$$

with *typing constraints* that successive endpoints and mode indices match (so the intermediate locus x_j and label α_j are "summed over" by composition; cf. Propositions 4.52 and 4.85). The *length* of W is the number of letters. Its *degree* is $\deg(W) := \sum_{k=1}^n \deg(\hat{G}^{\alpha_k \alpha_{k-1}})$ with deg as in Definition 4.94, and is well defined modulo the typing constraints.

Remark 4.142 (Endpoints, base, and transporter)**.** In all channel-word statements, endpoints x, x' are points of the PQS continuum $\mathcal{C}_d$ (Definition 4.617). Paths γ are piecewise C^1 curves in $\mathcal{C}_d$, and $\mathcal{U}(x \leftarrow x'; \gamma)$ is the gauge–covariant transporter of Section 4.19.1. Fibre restrictions at endpoints are as in (4.303). The emergent space $\mathcal{X}_q$ and the projection $\pi_q : \mathcal{C}_d \to \mathcal{X}_q$ are only introduced after forming the operational quotient (Definition 4.623 and eq. (4.322)); no statement in the words calculus depends on $\mathcal{X}_q$ prior to that quotient.

Proposition 4.143 (Covariance, adjoint, functoriality for words)**.** *Every channel word W satisfies:*

(i) Gauge covariance (endpoints)

Under a gauge map $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ one has

$$W(x_n, x_0) \;\mapsto\; g(x_n)\, W(x_n, x_0)\, g(x_0)^\dagger,$$

by repeated use of Proposition 4.54 and Corollary 4.64.

(ii) Adjoint/Hermitian symmetry

$W(x_n, x_0)^\dagger = W^\sharp(x_0, x_n)$ *where $W^\sharp$ is the word with reversed order and conjugated letters; uses Lemma 4.66 and Proposition 4.52.*

(iii) Path composition
Concatenating geometric segments $(x_0 \to \cdots \to x_m)$ *and* $(x_m \to \cdots \to x_n)$ *gives word multiplication, thanks to Proposition 4.52.*

(iv) Degree additivity
$\deg(W_1W_2) = \deg(W_1) + \deg(W_2)$ *and* $\deg(W^\dagger) = \deg(W)$, *by Definition 4.94 and Lemma 4.98.*

Proof of Proposition 4.143. (i) Gauge covariance. Each letter is $\hat{G}_\Lambda^{\alpha_j\alpha_{j-1}}(x_j, x_{j-1}) = \hat{\mathcal{F}}_{\alpha_j}^\dagger(x_j)\,\mathcal{U}(x_j \leftarrow x_{j-1}; \gamma_j)\,\hat{\mathcal{F}}_{\alpha_{j-1}}(x_{j-1})$. Under $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, Proposition 4.54 and Corollary 4.64 give $\hat{G}^{\alpha_j\alpha_{j-1}} \mapsto g(x_j)\hat{G}^{\alpha_j\alpha_{j-1}}g(x_{j-1})^\dagger$. Interior factors $g(x_j)^\dagger g(x_j)$ cancel in the ordered product, leaving $W(x_n, x_0) \mapsto g(x_n)W(x_n, x_0)g(x_0)^\dagger$.

(ii) Adjoint/Hermitian symmetry. Define the reverse–conjugate word

$$W^\sharp(x_0, x_n) := \left(\hat{G}_\Lambda^{\alpha_1\alpha_0}(x_1, x_0)\right)^\dagger \cdots \left(\hat{G}_\Lambda^{\alpha_n\alpha_{n-1}}(x_n, x_{n-1})\right)^\dagger.$$

By Lemma 4.66 and the adjoint reversing products, $W(x_n, x_0)^\dagger = W^\sharp(x_0, x_n)$. Equivalently, use Proposition 4.52 to note that adjoint reverses the underlying path concatenation.

(iii) Path composition. Concatenating segments corresponds to composing the intervening transporters by Proposition 4.52 and eq. (4.14); with selectors fixed at endpoints, this is exactly multiplication of the corresponding letters, hence of words.

(iv) Degree additivity. By Definition 4.94, each letter has degree $\deg(\alpha_j) + \deg(\alpha_{j-1})$; additivity under products and preservation under adjoint are Lemma 4.98. □

Corollary 4.144 (Endpoint degree rule for words)**.** *Let* $W = \hat{G}_\Lambda^{\alpha_n\alpha_{n-1}}(x_n, x_{n-1}) \cdots \hat{G}_\Lambda^{\alpha_1\alpha_0}(x_1, x_0)$ *be a channel word (Definition 4.141). Then*

$$\deg(W) = \deg(\alpha_n) + \deg(\alpha_0) \in \mathbb{Z}_2^2.$$

Proof. By Definition 4.94, each letter has degree $\deg(\alpha_j) + \deg(\alpha_{j-1})$. Summing from $j = 1$ to n yields $\sum_{j=1}^n \deg(\alpha_j) + \sum_{j=1}^n \deg(\alpha_{j-1}) = \deg(\alpha_n) + \deg(\alpha_0) + 2\sum_{j=1}^{n-1} \deg(\alpha_j)$, and the middle sum vanishes in $\mathbb{Z}_2^2$. □

Lemma 4.145 (Word-level graded selection and endpoint degree)**.** *Let*

$$W = \hat{G}_\Lambda^{\alpha_n\alpha_{n-1}}(x_n, x_{n-1}) \cdots \hat{G}_\Lambda^{\alpha_1\alpha_0}(x_1, x_0)$$

be a (channel) word as in Definition 4.141, with typing constraints satisfied. Then:

(i) Endpoint degree rule
The degree of the endpoint

$$\deg(W) = \sum_{j=1}^n \deg\left(\hat{G}_\Lambda^{\alpha_j\alpha_{j-1}}\right) = \deg(\alpha_n) + \deg(\alpha_0) \ \in \ \mathbb{Z}_2^2.$$

In particular, the total degree of W *depends only on its endpoint mode labels and is independent of the chosen factorization/path refinement.*

(ii) Stability under adjoint and gauge

$W^\dagger$ has the same degree, $\deg(W^\dagger) = \deg(W)$*, and under a gauge change* $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ *one has* $W(x_n, x_0) \mapsto g(x_n)\, W(x_n, x_0)\, g(x_0)^\dagger$ *with degree unchanged (Proposition 4.143, Lemma 4.98).*

(iii) Word-level selection rule (extension of Proposition 4.99)

If W is expanded by inserting dialectically complete resolutions at intermediate loci (Proposition 4.85), then every summand word $\widetilde{W}$ has the same *total degree* $\deg(\alpha_n) + \deg(\alpha_0)$*. Hence any putative contribution with mismatched total color cancels identically.*

Proof. (i) By Definition 4.94, each letter has degree $\deg(\alpha_j) + \deg(\alpha_{j-1})$. Summing over $j = 1, \ldots, n$ gives

$$\sum_{j=1}^{n} \Big(\deg(\alpha_j) + \deg(\alpha_{j-1}) \Big) = \deg(\alpha_n) + \deg(\alpha_0) + 2 \sum_{j=1}^{n-1} \deg(\alpha_j),$$

and the middle sum vanishes in $\mathbb{Z}_2^2$, yielding the endpoint formula.

(ii) Gauge covariance of words and adjoint reversal are in Proposition 4.143. Degree preservation under adjoint and additivity under products are in Lemma 4.98.

(iii) Inserting completeness at intermediates rewrites W as a finite sum of words with the same endpoints (α_0, α_n) (cf. Proposition 4.85). Each summand is a product of letters, so by (i) its degree is $\deg(\alpha_n) + \deg(\alpha_0)$, independent of the internal index sequence. □

Corollary 4.146 (Flatness reduction for words)**.** *If $\mathcal{F} = 0$ on a simply connected neighbourhood (Chapter 4; Proposition 4.59), then for any two factorizations of the same endpoints (x_0, x_n) the corresponding words agree up to endpoint gauge $g(x_n)\,(\cdot)\,g(x_0)^\dagger$. In particular, single-letter and multi-letter factorizations are equivalent in that region.*

Proof of Corollary 4.146. On a simply connected region with $\mathcal{F} = 0$, Proposition 4.59 implies that each transporter $\mathcal{U}(x_j \leftarrow x_{j-1}; \gamma_j)$ depends only on endpoints and reduces (after gauge choice) to the identity. Hence any factorization yields the same endpoint operator up to overall conjugation by $g(x_n), g(x_0)$, which establishes the claim for single- vs multi-letter factorizations. □

Remark 4.147 (Flatness and device–geometry separation)**.** In a flat, simply connected region (Proposition 4.59), the geometric part $\mathcal{U}(x \leftarrow x'; \gamma)$ reduces to an endpoint gauge choice. Word-level distinctions then live entirely in the device factor $\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}}$, while endpoint conjugation governs the overall covariance (Proposition 4.167).

Before introducing Definition 4.148, we briefly recall the Chapter 2 setting that the holosymmetric wordwise construction lives in. The holosymmetric device operates on the composite Hilbert space

$$\mathcal{H}_{\mathrm{Holo}} \;=\; \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)} \quad \text{(cf. Definition 2.101 and eq. (2.62)).}$$

Here, $\mathcal{H}_c$ is the control register admitting the computational basis $\{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$ and the X-basis $\{|+\rangle, |-\rangle\}$, while $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ is the dual-register arena on which the two parallel histories

act. The device alphabet $\mathsf{A}_{\mathrm{holo}}$ collects the primitive letters that generate every device-level operation used in the interferometric constructions of Chapter 2: (i) the control projectors $|\mathbf{0}\rangle\langle\mathbf{0}|_c$, $|\mathbf{1}\rangle\langle\mathbf{1}|_c$ for preparation and readout in the computational basis of $\mathcal{H}_c$; (ii) the control unitaries $U_c^{\mathrm{prep}}, U_c^{\mathrm{read}}$ (with the Hadamard H_c providing the canonical switch to the X-basis used in interference readout); (iii) the RR path operators $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, which implement the two branch evolutions defined by the parallel-path construction (Definition 2.108 and eqs. (2.69) and (2.70)); and (iv) the controlled and Hadamard-wrapped stacks $\mathbf{U}_{\mathrm{ctrl}}$ and $\mathbf{U}_{\mathrm{Had}}$ that realize, respectively, branch selection and coherent branch interference on the control line (Definitions 2.114 and 2.119 and eqs. (2.75), (2.78) and (2.79)). Any finite product of letters from $\mathsf{A}_{\mathrm{holo}}$ defines a *holosymmetric word* $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ acting on $\mathcal{H}_{\mathrm{Holo}}$.

Given control boundary conditions $|\chi_{\mathrm{in}}\rangle, |\chi_{\mathrm{out}}\rangle \in \mathcal{H}_c$, the corresponding *RR–matrix element* of a holosymmetric word is the branch-resolved operator

$$\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}} := (\langle \chi_{\mathrm{out}}|_c \otimes I)\, \mathbf{W}\, (|\chi_{\mathrm{in}}\rangle_c \otimes I) \quad (\text{eq. } (4.45)). \tag{4.43}$$

This partial matrix element "reads off" the RR evolution conditioned on the control transition $\chi_{\mathrm{in}} \to \chi_{\mathrm{out}}$, and it is the natural object in which pathwise and interference statements of Chapter 2 become algebraically transparent. Two canonical specializations recover the standard constructions exactly. First, for the controlled splitter

$$\mathbf{U}_{\mathrm{ctrl}} \;=\; |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \;+\; |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \quad (\textit{eq. } (2.75)),$$

the only nonzero RR–matrix elements in the computational basis are

$$\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{0}} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \qquad \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{1}} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}, \qquad \mathsf{W}_{\mathbf{0}\leftarrow\mathbf{1}} = \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{0}} = 0,$$

which is precisely the parallel-path decomposition. Second, for the Hadamard-wrapped interferometer $\mathbf{U}_{\mathrm{Had}} = (H_c \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (H_c \otimes I)$ (eq. (2.78)), working in the X-basis $|\pm\rangle_c = (|\mathbf{0}\rangle \pm |\mathbf{1}\rangle)/\sqrt{2}$ yields

$$\mathsf{W}_{+\leftarrow+} \;=\; \tfrac{1}{2}\Big(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\Big) \;=\; \tfrac{1}{2}\,\hat{\mathbf{U}}_{+}, \qquad \mathsf{W}_{-\leftarrow+} \;=\; \tfrac{1}{2}\Big(\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} - \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\Big) \;=\; \tfrac{1}{2}\,\hat{\mathbf{U}}_{-},$$

and similarly for the other control transitions, thereby realizing the sum/difference interferometers of eq. (2.79) directly as RR–matrix elements.

Composition of words descends to a *control-resolved convolution* on RR–matrix elements. For any chosen control basis $\mathcal{B}_c$ (e.g., computational $\{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$ or X-basis $\{|+\rangle, |-\rangle\}$),

$$(\mathbf{W}_2 \mathbf{W}_1)_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}} \;=\; \sum_{\chi \in \mathcal{B}_c} \mathsf{W}_{2,\ \chi_{\mathrm{out}} \leftarrow \chi}\ \mathsf{W}_{1,\ \chi \leftarrow \chi_{\mathrm{in}}}, \tag{4.44}$$

so algebraic manipulations and proofs in the wordwise formalism can be carried out entirely at the level of RR–matrix elements, with the control modes furnishing the natural contraction indices.

Finally, we record the link back to the Chapter 2 dynamics and generators. Each RR path operator admits an internal factorization through the parasymmetric building blocks,

$$\hat{\mathbf{U}}_{\mathrm{RR}}^{(\cdot)} \;\rightsquigarrow\; U_L \;\otimes\; U_P \;\otimes\; U_G, \qquad U_P \;=\; \exp\!\Big(i \sum_{i<j} J_{ij}\, \big(P_{\mathrm{para}}^{(ij)} - P_{\mathrm{antipara}}^{(ij)}\big)\Big),$$

consistent with the pairwise generator $\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}$ and the composite evolution $U_N^{(\odot)}$ from Chapter 2. While the wordwise viewpoint treats such RR evolutions as opaque letters of $\mathsf{A}_{\mathrm{holo}}$, unitarity on $\mathcal{H}_{\mathrm{Holo}}$ enforces isometric *mixing bounds* on their RR–matrix elements—constraints that will be invoked later in the wordwise kinematics and mixing analysis.

Definition 4.148 (Holosymmetric word (device level))**.** In the holosymmetric space of Chapter 2 (Definition 2.101 and eq. (2.62)), let the *device alphabet* be

$$\mathsf{A}_{\mathrm{holo}} = \Big\{\, |\mathbf{0}\rangle\langle\mathbf{0}|_c,\ |\mathbf{1}\rangle\langle\mathbf{1}|_c,\ U_c^{\mathrm{prep}}, U_c^{\mathrm{read}},\ \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N},\ \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} \,\Big\},$$

with the RR path operators and control gates as in Definitions 2.108, 2.114 and 2.119 and eqs. (2.69) and (2.70). A *holosymmetric word* is any finite product $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ acting on $\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$.

Given control states $|\chi_{\mathrm{in}}\rangle, |\chi_{\mathrm{out}}\rangle \in \mathcal{H}_c$, the *RR-matrix element* (branch-resolved word) is the operator on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$:

$$\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}} \;:=\; \Big(\langle\chi_{\mathrm{out}}|_c \otimes I\Big)\ \mathbf{W}\ \Big(|\chi_{\mathrm{in}}\rangle_c \otimes I\Big). \tag{4.45}$$

For $\mathbf{W} = \mathbf{U}_{\mathrm{ctrl}}$ or $\mathbf{U}_{\mathrm{Had}}$ this reproduces the parallel-path decompositions and sum/difference interferometers of eqs. (2.75), (2.78) and (2.79).

RR dual-register and holosymmetric device space (recall from Ch. 2). Let A and B denote the two n-PQS registers. The dual-register Hilbert space is

$$\mathcal{H}_{\mathrm{RR}}^{(2n)} \;:=\; \mathcal{H}_{\mathrm{PQS}}^{(n,A)} \otimes \mathcal{H}_{\mathrm{PQS}}^{(n,B)},$$

and the holosymmetric device acts on

$$\mathcal{H}_{\mathrm{Holo}} \;=\; \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)} \quad \text{(cf. Definition 2.101 and eq. (2.62)).}$$

Here $\mathcal{H}_c$ is the control register with computational basis $\{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$ and X-basis $\{|+\rangle, |-\rangle\}$. The two parallel RR evolutions $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ are the branch operators of the parallel-path construction (cf. Definition 2.108 and eqs. (2.69) and (2.70)), which are multiplexed by the control via $\mathbf{U}_{\mathrm{ctrl}}$ and Hadamard-wrapped in $\mathbf{U}_{\mathrm{Had}}$ for interference (cf. Definitions 2.114 and 2.119 and eqs. (2.75), (2.78) and (2.79)).

Wordwise alphabet and words (device level). Let $\mathsf{A}_{\mathrm{holo}}$ denote the device alphabet consisting of the control projectors $\{|\mathbf{0}\rangle\langle\mathbf{0}|_c, |\mathbf{1}\rangle\langle\mathbf{1}|_c\}$, control unitaries $\{U_c^{\mathrm{prep}}, U_c^{\mathrm{read}}\}$ (e.g. H_c), and the RR branch operators $\{\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\}$, together with the controlled and Hadamard-conjugated stacks $\{\mathbf{U}_{\mathrm{ctrl}}, \mathbf{U}_{\mathrm{Had}}\}$. A *holosymmetric word* is any finite product $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ acting on $\mathcal{H}_{\mathrm{Holo}}$ (cf. Definition 4.148).

RR–matrix elements (branch-resolved operators). Given $|\chi_{\mathrm{in}}\rangle, |\chi_{\mathrm{out}}\rangle \in \mathcal{H}_c$, the RR–matrix element of a word $\mathbf{W}$ is

$$\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}} \;:=\; (\langle\chi_{\mathrm{out}}|_c \otimes I)\ \mathbf{W}\ (|\chi_{\mathrm{in}}\rangle_c \otimes I), \tag{4.46}$$

an operator on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ that "reads off" the RR branch selected by the control transition (cf. eq. (4.45)). Throughout, we use either the computational basis $\mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$ or the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$ with $|\pm\rangle = (|\mathbf{0}\rangle \pm |\mathbf{1}\rangle)/\sqrt{2}$.

Lemma 4.149 (Control-resolved convolution)**.** *For any words* $\mathbf{W}_2, \mathbf{W}_1 \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ *and any orthonormal control basis* $\mathcal{B}_c \subset \mathcal{H}_c$*,*

$$(\mathbf{W}_2\mathbf{W}_1)_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} = \sum_{\chi\in\mathcal{B}_c} \mathsf{W}_{2,\ \chi_{\mathrm{out}}\leftarrow\chi}\ \mathsf{W}_{1,\ \chi\leftarrow\chi_{\mathrm{in}}}. \tag{4.47}$$

Proof. Fix words $\mathbf{W}_2, \mathbf{W}_1 \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ (cf. Definition 4.148), and let $|\chi_{\mathrm{in}}\rangle, |\chi_{\mathrm{out}}\rangle \in \mathcal{H}_c$ be arbitrary. By the definition of RR–matrix elements $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ (see eq. (4.45)), we have

$$(\mathbf{W}_2\mathbf{W}_1)_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} = \Big(\langle\chi_{\mathrm{out}}|_c \otimes I\Big)\ \mathbf{W}_2\mathbf{W}_1\ \Big(|\chi_{\mathrm{in}}\rangle_c \otimes I\Big).$$

Insert the resolution of the identity on the control register in any orthonormal control basis $\mathcal{B}_c \subset \mathcal{H}_c$, $I_c = \sum_{\chi\in\mathcal{B}_c} |\chi\rangle\langle\chi|$, tensorized with the RR identity I. This yields

$$\begin{aligned}(\mathbf{W}_2\mathbf{W}_1)_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} &= \sum_{\chi\in\mathcal{B}_c} \Big(\langle\chi_{\mathrm{out}}|_c \otimes I\Big)\ \mathbf{W}_2\ \Big(|\chi\rangle_c\langle\chi|_c \otimes I\Big)\ \mathbf{W}_1\ \Big(|\chi_{\mathrm{in}}\rangle_c \otimes I\Big) \\ &= \sum_{\chi\in\mathcal{B}_c} \underbrace{\Big(\langle\chi_{\mathrm{out}}|_c \otimes I\Big)\ \mathbf{W}_2\ \Big(|\chi\rangle_c \otimes I\Big)}_{\mathsf{W}_{2,\ \chi_{\mathrm{out}}\leftarrow\chi}}\ \underbrace{\Big(\langle\chi|_c \otimes I\Big)\ \mathbf{W}_1\ \Big(|\chi_{\mathrm{in}}\rangle_c \otimes I\Big)}_{\mathsf{W}_{1,\ \chi\leftarrow\chi_{\mathrm{in}}}}.\end{aligned}$$

Each underbraced factor is, by eq. (4.45), precisely the RR–matrix element of the corresponding word with the indicated control transition. Hence

$$(\mathbf{W}_2\mathbf{W}_1)_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} = \sum_{\chi\in\mathcal{B}_c} \mathsf{W}_{2,\ \chi_{\mathrm{out}}\leftarrow\chi}\ \mathsf{W}_{1,\ \chi\leftarrow\chi_{\mathrm{in}}},$$

which is eq. (4.47). The choice of $\mathcal{B}_c$ is immaterial since any two orthonormal control bases are related by a unitary (e.g. H_c maps the computational basis to the X-basis; cf. Definition 2.119), and inserting I_c is basis-independent. This completes the proof. □

Remark 4.150 (Meaning of control-resolved convolution)**.** The identity Lemma 4.149 and eq. (4.47) says that, once we fix an orthonormal control basis $\mathcal{B}_c \subset \mathcal{H}_c$, every device word $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ behaves as a $|\mathcal{B}_c| \times |\mathcal{B}_c|$ *block operator matrix* whose entries are precisely the RR–matrix elements $\{\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\}_{\chi_{\mathrm{out}},\chi_{\mathrm{in}}\in\mathcal{B}_c}$ (cf. Definition 4.148 and eq. (4.45)). In this representation,

$$\mathbf{W} \ \longleftrightarrow\ \Big[\ \mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\ \Big]_{\chi_{\mathrm{out}},\chi_{\mathrm{in}}\in\mathcal{B}_c},$$

and composition of words corresponds to *ordinary block-matrix multiplication* with operator-valued blocks on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$. Concretely, the product $\mathbf{W}_2\mathbf{W}_1$ has $(\chi_{\mathrm{out}}, \chi_{\mathrm{in}})$-entry given by the contraction over the intermediate control label χ,

$$(\mathbf{W}_2\mathbf{W}_1)_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} = \sum_{\chi\in\mathcal{B}_c} \mathsf{W}_{2,\ \chi_{\mathrm{out}}\leftarrow\chi}\ \mathsf{W}_{1,\ \chi\leftarrow\chi_{\mathrm{in}}},$$

which is exactly eq. (4.47). Equivalently, eq. (4.47) is nothing but the insertion of the control identity $I_c = \sum_{\chi\in\mathcal{B}_c} |\chi\rangle\langle\chi|$ between $\mathbf{W}_2$ and $\mathbf{W}_1$ and evaluation of partial matrix elements on $\mathcal{H}_c$ (cf. eq. (4.45)).

Three immediate consequences clarify its role in the wordwise calculus. *(i) Basis covariance:* the statement is independent of the choice of $\mathcal{B}_c$, since any two orthonormal control

bases are related by a unitary on $\mathcal{H}_c$ (e.g. the Hadamard H_c that implements the $Z \leftrightarrow X$ change of basis; cf. Definition 2.119). *(ii) Interferometric readability:* choosing $\mathcal{B}_c = \{|+\rangle, |-\rangle\}$ turns the blocks into the sum/difference channels that realize the standard interferometer identities of Chapter 2 (cf. eqs. (2.78) and (2.79)). *(iii) Unitarity constraints:* applying eq. (4.47) to $\mathbf{W}^\dagger\mathbf{W} = I$ and $\mathbf{W}\mathbf{W}^\dagger = I$ yields the block *mixing bounds* of Corollary 4.151, i.e. left/right RR–isometries obtained by summing over control outcomes. Thus Lemma 4.149 is the algebraic backbone that lets us carry out device-level proofs purely at the RR–matrix level while retaining full operator-level correctness on $\mathcal{H}_{\text{Holo}}$.

Corollary 4.151 (Block unitarity ⇒ mixing bounds)**.** *If* $\mathbf{W}$ *is unitary on* $\mathcal{H}_{\text{Holo}}$*, then for any orthonormal control basis* $\mathcal{B}_c$*,*

$$\sum_{\chi\in\mathcal{B}_c} \mathsf{W}^\dagger_{\chi\leftarrow\chi_{\text{in}}}\,\mathsf{W}_{\chi\leftarrow\chi_{\text{in}}} \;=\; I_{\text{RR}}, \qquad \sum_{\chi\in\mathcal{B}_c} \mathsf{W}_{\chi_{\text{out}}\leftarrow\chi}\,\mathsf{W}^\dagger_{\chi_{\text{out}}\leftarrow\chi} \;=\; I_{\text{RR}}. \tag{4.48}$$

Proof. Let $\mathbf{W} \in \langle \mathsf{A}_{\text{holo}} \rangle$ be unitary on $\mathcal{H}_{\text{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\text{RR}}^{(2n)}$ (cf. Definitions 2.101 and 4.148 and eq. (2.62)). Fix any orthonormal control basis $\mathcal{B}_c \subset \mathcal{H}_c$ and a control state $|\chi_{\text{in}}\rangle \in \mathcal{B}_c$. By unitarity, $\mathbf{W}^\dagger\mathbf{W} = I_{\mathcal{H}_{\text{Holo}}}$. Taking the RR–matrix element in the sense of eq. (4.45), we obtain

$$(\mathbf{W}^\dagger\mathbf{W})_{\chi_{\text{in}}\leftarrow\chi_{\text{in}}} = (\langle\chi_{\text{in}}|_c \otimes I)\,\mathbf{W}^\dagger\mathbf{W}\,(|\chi_{\text{in}}\rangle_c \otimes I) = (\langle\chi_{\text{in}}|_c \otimes I)\,I_{\mathcal{H}_{\text{Holo}}}\,(|\chi_{\text{in}}\rangle_c \otimes I) = I_{\text{RR}}.$$

On the other hand, by the control-resolved convolution Lemma 4.149 and eq. (4.47) with $\mathbf{W}_2 = \mathbf{W}^\dagger$ and $\mathbf{W}_1 = \mathbf{W}$,

$$(\mathbf{W}^\dagger\mathbf{W})_{\chi_{\text{in}}\leftarrow\chi_{\text{in}}} = \sum_{\chi\in\mathcal{B}_c} (\mathbf{W}^\dagger)_{\chi_{\text{in}}\leftarrow\chi}\;\mathbf{W}_{\chi\leftarrow\chi_{\text{in}}}.$$

Using the definition of RR–matrix elements eq. (4.45) and the adjoint rule $(\langle a| \otimes I)\,\mathbf{W}^\dagger\,(|b\rangle \otimes I) = \Big((\langle b| \otimes I)\,\mathbf{W}\,(|a\rangle \otimes I)\Big)^\dagger$, we identify $(\mathbf{W}^\dagger)_{\chi_{\text{in}}\leftarrow\chi} = \Big(\mathbf{W}_{\chi\leftarrow\chi_{\text{in}}}\Big)^\dagger$. Hence

$$I_{\text{RR}} = (\mathbf{W}^\dagger\mathbf{W})_{\chi_{\text{in}}\leftarrow\chi_{\text{in}}} = \sum_{\chi\in\mathcal{B}_c} \mathbf{W}^\dagger_{\chi\leftarrow\chi_{\text{in}}}\,\mathbf{W}_{\chi\leftarrow\chi_{\text{in}}},$$

which is the first identity in eq. (4.48).

For the second identity, apply the same reasoning to $\mathbf{W}\mathbf{W}^\dagger = I_{\mathcal{H}_{\text{Holo}}}$ and take the RR–matrix element $(\mathbf{W}\mathbf{W}^\dagger)_{\chi_{\text{out}}\leftarrow\chi_{\text{out}}} = I_{\text{RR}}$. By Lemma 4.149 and eq. (4.47) with $\mathbf{W}_2 = \mathbf{W}$ and $\mathbf{W}_1 = \mathbf{W}^\dagger$,

$$I_{\text{RR}} = \sum_{\chi\in\mathcal{B}_c} \mathbf{W}_{\chi_{\text{out}}\leftarrow\chi}\,(\mathbf{W}^\dagger)_{\chi\leftarrow\chi_{\text{out}}} = \sum_{\chi\in\mathcal{B}_c} \mathbf{W}_{\chi_{\text{out}}\leftarrow\chi}\,\Big(\mathbf{W}_{\chi_{\text{out}}\leftarrow\chi}\Big)^\dagger,$$

which is the second identity in eq. (4.48). Since inserting the control identity $I_c = \sum_{\chi\in\mathcal{B}_c} |\chi\rangle\langle\chi|$ is basis-independent and any two orthonormal control bases are related by a unitary on $\mathcal{H}_c$ (e.g., the Hadamard H_c; cf. Definition 2.119), the result holds for any $\mathcal{B}_c$. This proves Corollary 4.151. □

Proposition 4.152 (Controlled splitter: parallel-path decomposition)**.** *For* $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ *(cf. eq. (2.75)), the only nonzero RR–matrix elements in* $\mathcal{B}_c^{(Z)}$ *are*

$$\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{0}} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}, \qquad \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{1}} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}, \qquad \mathsf{W}_{\mathbf{0}\leftarrow\mathbf{1}} = \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{0}} = 0. \tag{4.49}$$

Proof. Work in the computational control basis $\mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\} \subset \mathcal{H}_c$. By the definition of RR–matrix elements (eq. (4.45)), for any $\chi_{\mathrm{out}}, \chi_{\mathrm{in}} \in \mathcal{B}_c^{(Z)}$,

$$\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}} = \Big(\langle\chi_{\mathrm{out}}|_c \otimes I\Big)\ \mathbf{U}_{\mathrm{ctrl}}\ \Big(|\chi_{\mathrm{in}}\rangle_c \otimes I\Big),$$

with $\mathbf{U}_{\mathrm{ctrl}}$ given by eq. (2.75): $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$.

Diagonal entries. For $\chi_{\mathrm{out}} = \chi_{\mathrm{in}} = \mathbf{0}$,

$$\begin{aligned}\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{0}} &= \Big(\langle\mathbf{0}|_c \otimes I\Big)\Big[\ |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}\ \Big]\Big(|\mathbf{0}\rangle_c \otimes I\Big) \\ &= \big(\langle\mathbf{0}|\mathbf{0}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \big(\langle\mathbf{0}|\mathbf{1}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N},\end{aligned}$$

since $\langle\mathbf{0}|\mathbf{0}\rangle = 1$ and $\langle\mathbf{0}|\mathbf{1}\rangle = 0$. Similarly, for $\chi_{\mathrm{out}} = \chi_{\mathrm{in}} = \mathbf{1}$,

$$\begin{aligned}\mathsf{W}_{\mathbf{1}\leftarrow\mathbf{1}} &= \Big(\langle\mathbf{1}|_c \otimes I\Big)\ \mathbf{U}_{\mathrm{ctrl}}\ \Big(|\mathbf{1}\rangle_c \otimes I\Big) \\ &= \big(\langle\mathbf{1}|\mathbf{0}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \big(\langle\mathbf{1}|\mathbf{1}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}.\end{aligned}$$

Off-diagonal entries. For $\chi_{\mathrm{out}} = \mathbf{0},\ \chi_{\mathrm{in}} = \mathbf{1}$,

$$\begin{aligned}\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{1}} &= \Big(\langle\mathbf{0}|_c \otimes I\Big)\ \mathbf{U}_{\mathrm{ctrl}}\ \Big(|\mathbf{1}\rangle_c \otimes I\Big) \\ &= \big(\langle\mathbf{0}|\mathbf{0}\rangle\big)\big(\langle\mathbf{0}|\mathbf{1}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + \big(\langle\mathbf{0}|\mathbf{1}\rangle\big)\big(\langle\mathbf{1}|\mathbf{1}\rangle\big)\,\hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G} = 0,\end{aligned}$$

and analogously $\mathsf{W}_{\mathbf{1}\leftarrow\mathbf{0}} = 0$. Equivalently, using projector calculus on $\mathcal{H}_c$, $|\mathbf{a}\rangle\langle\mathbf{a}| \cdot |\mathbf{b}\rangle\langle\mathbf{b}| = \delta_{\mathbf{ab}}\,|\mathbf{a}\rangle\langle\mathbf{a}|$, so the cross terms vanish by orthogonality of $|\mathbf{0}\rangle$ and $|\mathbf{1}\rangle$.

Collecting the four cases gives exactly the identities in eq. (4.49). Hence, in $\mathcal{B}_c^{(Z)}$ the only nonzero RR–matrix elements are the two diagonal blocks, each equal to its corresponding RR path operator, which proves the parallel-path decomposition claimed. □

Proposition 4.153 (Hadamard-wrapped interferometer: sum/difference channels)**.** *Let* $\mathbf{U}_{\mathrm{Had}} = (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$ *(cf. eq. (2.78)) and define* $\hat{\mathbf{U}}_{\pm} := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \pm \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ *(cf. eq. (2.79)). Then in the* X*-basis* $\mathcal{B}_c^{(X)}$*,*

$$\mathsf{W}_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{+}, \quad \mathsf{W}_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{-}, \quad \mathsf{W}_{+\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{-}, \quad \mathsf{W}_{-\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{+}. \tag{4.50}$$

Thus measuring the control in $|\pm\rangle$ *realizes the sum/difference interferometers of Chapter 2.*

Proof. Let $\mathbf{U}_{\mathrm{Had}} = (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$ as in eq. (2.78), with $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ (eq. (2.75)). Write $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, and recall $\hat{\mathbf{U}}_{\pm} := A \pm B$ (eq. (2.79)). We first compute the RR–matrix elements of $\mathbf{U}_{\mathrm{Had}}$ in the computational basis $\mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$, then translate the indices to the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$ using H_c (cf. Definition 2.119).

By definition of RR–matrix elements (eq. (4.45)), for $\mathbf{a}, \mathbf{b} \in \{\mathbf{0}, \mathbf{1}\}$,

$$\mathsf{W}_{\mathbf{a}\leftarrow\mathbf{b}} = (\langle \mathbf{a}|_c \otimes I)\,(H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)\,(|\mathbf{b}\rangle_c \otimes I).$$

Insert the control identity in the Z-basis on both sides of $\mathbf{U}_{\mathrm{ctrl}}$, $I_c = \sum_{i\in\{\mathbf{0},\mathbf{1}\}} |i\rangle\langle i|$, and use $\mathbf{U}_{\mathrm{ctrl}}$ being diagonal in $\mathcal{B}_c^{(Z)}$ together with Proposition 4.152 and eq. (4.49):

$$(\langle i|_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(|j\rangle_c \otimes I) \;=\; \delta_{ij} \times \begin{cases} A, & i = \mathbf{0}, \\ B, & i = \mathbf{1}. \end{cases}$$

Therefore

$$\begin{aligned} \mathsf{W}_{\mathbf{a}\leftarrow\mathbf{b}} &= \sum_{i\in\{\mathbf{0},\mathbf{1}\}} \big(\langle \mathbf{a}|H_c|i\rangle\big)\,\big(\langle i|H_c|\mathbf{b}\rangle\big) \;\times \begin{cases} A, & i = \mathbf{0}, \\ B, & i = \mathbf{1}, \end{cases} \\ &= \big(\langle \mathbf{a}|H_c|\mathbf{0}\rangle\big)\big(\langle \mathbf{0}|H_c|\mathbf{b}\rangle\big)\,A + \big(\langle \mathbf{a}|H_c|\mathbf{1}\rangle\big)\big(\langle \mathbf{1}|H_c|\mathbf{b}\rangle\big)\,B. \end{aligned}$$

Using the Hadamard overlaps in the Z-basis,

$$\langle \mathbf{0}|H_c|\mathbf{0}\rangle = \langle \mathbf{0}|H_c|\mathbf{1}\rangle = \langle \mathbf{1}|H_c|\mathbf{0}\rangle = \tfrac{1}{\sqrt{2}}, \qquad \langle \mathbf{1}|H_c|\mathbf{1}\rangle = -\tfrac{1}{\sqrt{2}},$$

one obtains the four entries:

$$\begin{aligned} \mathsf{W}_{\mathbf{0}\leftarrow\mathbf{0}} &= \tfrac{1}{2}(A+B) = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, & \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{0}} &= \tfrac{1}{2}(A-B) = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \\ \mathsf{W}_{\mathbf{0}\leftarrow\mathbf{1}} &= \tfrac{1}{2}(A-B) = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, & \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{1}} &= \tfrac{1}{2}(A+B) = \tfrac{1}{2}\,\hat{\mathbf{U}}_+. \end{aligned}$$

Finally, since H_c maps $\mathcal{B}_c^{(Z)}$ to $\mathcal{B}_c^{(X)}$ via $|+\rangle = H_c|\mathbf{0}\rangle$, $|-\rangle = H_c|\mathbf{1}\rangle$ (cf. Definition 2.119), the same block relations hold upon relabeling $\mathbf{0} \leftrightarrow +$ and $\mathbf{1} \leftrightarrow -$. Thus, in the X-basis $\mathcal{B}_c^{(X)}$,

$$\mathsf{W}_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, \quad \mathsf{W}_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad \mathsf{W}_{+\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad \mathsf{W}_{-\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+,$$

which is eq. (4.50). Hence measuring the control in $|\pm\rangle$ realizes the sum/difference interferometers of Chapter 2. □

Proposition 4.154 (Equivalence of symmetric holo-interferometer constructions)**.** *Let* $\mathbf{U}_{\mathrm{sym}} := \mathbf{U}_{\mathrm{Had}}\ \mathbf{U}_{\mathrm{ctrl}}\ \mathbf{U}_{\mathrm{Had}}$. *Then* $\{\mathsf{U}^{\mathrm{sym}}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\}$ *computed via Lemma 4.149 and Propositions 4.152 and 4.153 coincide with the RR–matrix elements of the symmetric holo-interferometer* $\mathbf{U}^{(\mathrm{sym})}_{holo}$ *as defined in Chapter 2 (cf. eq. (2.79)). Consequently,* $\mathbf{U}_{\mathrm{sym}} = \mathbf{U}^{(\mathrm{sym})}_{holo}$ *on* $\mathcal{H}_{\mathrm{Holo}}$.

Proof. Let $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, and set $\hat{\mathbf{U}}_\pm := A \pm B$ (cf. eq. (2.79)). We work in the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$ with $|\pm\rangle = \frac{1}{\sqrt{2}}(|\mathbf{0}\rangle \pm |\mathbf{1}\rangle)$ (cf. Definition 2.119). By definition, $\mathbf{U}_{\mathrm{sym}} := \mathbf{U}_{\mathrm{Had}}\ \mathbf{U}_{\mathrm{ctrl}}\ \mathbf{U}_{\mathrm{Had}}$, where $\mathbf{U}_{\mathrm{Had}} = (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$ (eq. (2.78)) and $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B$ (eq. (2.75)).

Step 1: Block form of the factors in $\mathcal{B}_c^{(X)}$. From Proposition 4.153 and eq. (4.50) we already have, in the X-basis,

$$(\mathbf{U}_{\mathrm{Had}})_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, \quad (\mathbf{U}_{\mathrm{Had}})_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad (\mathbf{U}_{\mathrm{Had}})_{+\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad (\mathbf{U}_{\mathrm{Had}})_{-\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+. \tag{4.51}$$

A direct change-of-basis computation (insert $I_c = |\mathbf{0}\rangle\langle\mathbf{0}| + |\mathbf{1}\rangle\langle\mathbf{1}|$ and use $|\pm\rangle = \frac{1}{\sqrt{2}}(|\mathbf{0}\rangle \pm |\mathbf{1}\rangle)$) gives the same block pattern for $\mathbf{U}_{\mathrm{ctrl}}$ in $\mathcal{B}_c^{(X)}$:

$$(\mathbf{U}_{\mathrm{ctrl}})_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, \quad (\mathbf{U}_{\mathrm{ctrl}})_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad (\mathbf{U}_{\mathrm{ctrl}})_{+\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-, \quad (\mathbf{U}_{\mathrm{ctrl}})_{-\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, \tag{4.52}$$

which is also consistent with Proposition 4.152 and eq. (4.49) and the basis change implemented by H_c (cf. Definition 2.119).

Equations (4.51)–(4.52) can be summarized as the identical 2×2 block matrix (with operator entries on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$):

$$\mathbf{B} := \frac{1}{2}\begin{pmatrix} \hat{\mathbf{U}}_+ & \hat{\mathbf{U}}_- \\ \hat{\mathbf{U}}_- & \hat{\mathbf{U}}_+ \end{pmatrix}, \qquad \text{so that} \quad \mathbf{U}_{\mathrm{Had}} \leftrightarrow \mathbf{B}, \quad \mathbf{U}_{\mathrm{ctrl}} \leftrightarrow \mathbf{B} \quad \text{in } \mathcal{B}_c^{(X)}. \tag{4.53}$$

Step 2: Convolution (block) multiplication. By the control-resolved convolution Lemma 4.149 and eq. (4.47) (associativity by iterated insertion of I_c), the RR–matrix of the product $\mathbf{U}_{\mathrm{sym}} = \mathbf{U}_{\mathrm{Had}}\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{Had}}$ in the X-basis is the block product

$$\mathbf{U}_{\mathrm{sym}} \leftrightarrow \mathbf{B}\cdot\mathbf{B}\cdot\mathbf{B} = \mathbf{B}^3.$$

A straightforward induction on m shows the operator identity

$$\mathbf{B}^m = \frac{1}{2}\begin{pmatrix} A^m + B^m & A^m - B^m \\ A^m - B^m & A^m + B^m \end{pmatrix}, \qquad m \in \mathbb{N}, \tag{4.54}$$

with the $m = 1$ case given by (4.53) and the step $m \to m+1$ following from block multiplication and the ring identities $(A \pm B)(A^m \pm B^m) = A^{m+1} \pm B^{m+1}$ and $(A \pm B)(A^m \mp B^m) = A^{m+1} \mp B^{m+1}$. Specializing (4.54) to $m = 3$ yields

$$\mathbf{U}_{\mathrm{sym}} \leftrightarrow \frac{1}{2}\begin{pmatrix} A^3 + B^3 & A^3 - B^3 \\ A^3 - B^3 & A^3 + B^3 \end{pmatrix}. \tag{4.55}$$

Step 3: Identification with the Chapter 2 symmetric device. By the Chapter 2 parallel-path semantics *eq.* (2.79) (applied to the three-stage symmetric wrapper), the RR–matrix elements of the symmetric holo-interferometer $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ in the X-basis are precisely

$$\mathsf{U}^{(\mathrm{sym})}_{+\leftarrow+} = \tfrac{1}{2}(A^3 + B^3), \quad \mathsf{U}^{(\mathrm{sym})}_{-\leftarrow+} = \tfrac{1}{2}(A^3 - B^3), \quad \mathsf{U}^{(\mathrm{sym})}_{+\leftarrow-} = \tfrac{1}{2}(A^3 - B^3), \quad \mathsf{U}^{(\mathrm{sym})}_{-\leftarrow-} = \tfrac{1}{2}(A^3 + B^3),$$

matching entrywise the block matrix in (4.55). Therefore the families of RR–matrix elements coincide: $\{\mathsf{U}^{\mathrm{sym}}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\} = \{\mathsf{U}^{(\mathrm{sym})}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\}$. Since equality of all RR–matrix elements in an orthonormal control basis implies equality of the underlying operators on $\mathcal{H}_{\mathrm{Holo}} = \mathcal{H}_c \otimes \mathcal{H}_{\mathrm{RR}}^{(2n)}$ (by reconstruction from partial matrix elements; cf. eq. (4.45)), we conclude $\mathbf{U}_{\mathrm{sym}} = \mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$, as claimed. □

Remark 4.155 (Why Proposition 4.154 is not tautological)**.** Chapter 2 specifies the symmetric holo-interferometer $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ by its RR–matrix behavior in the X-basis—namely, the sum/difference channels governed by $\hat{\mathbf{U}}_\pm$ (cf. eq. (2.79)). In contrast, the word $\mathbf{U}_{\mathrm{sym}} := \mathbf{U}_{\mathrm{Had}}\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{Had}}$

is an implementation built from letters in $\mathsf{A}_{\mathrm{holo}}$. The proof of Proposition 4.154 uses only the RR–extraction eq. (4.45), the block forms of $\mathbf{U}_{\mathrm{ctrl}}$ and $\mathbf{U}_{\mathrm{Had}}$ (Propositions 4.152 and 4.153), and the control-resolved convolution (Lemma 4.149) to show that the two RR–matrix families coincide entrywise. Thus the proposition asserts *equivalence of specification and implementation*. It would become tautological *only* if $\mathbf{U}_{\mathrm{holo}}^{(\mathrm{sym})}$ were *defined* to be the same three-gate word; but under the behavioral definition via $\hat{\mathbf{U}}_{\pm}$, the equivalence is a contentful statement.

Proposition 4.156 (Uniqueness from RR–specification: reconstruction of the symmetric device)**.** *Let* $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ *and* $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ *be the two RR branch operators and set* $\hat{\mathbf{U}}_{\pm} := A \pm B$ *(cf. eq. (2.79)). Suppose* $\mathbf{U}$ *is any device on* $\mathcal{H}_{\mathrm{Holo}}$ *whose RR–matrix elements in the* X*-basis* $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$ *satisfy*

$$\mathbf{U} \;\leftrightarrow\; \begin{bmatrix} \mathsf{U}_{+\leftarrow+} & \mathsf{U}_{+\leftarrow-} \\ \mathsf{U}_{-\leftarrow+} & \mathsf{U}_{-\leftarrow-} \end{bmatrix} = \frac{1}{2}\begin{bmatrix} \hat{\mathbf{U}}_{+} & \hat{\mathbf{U}}_{-} \\ \hat{\mathbf{U}}_{-} & \hat{\mathbf{U}}_{+} \end{bmatrix}. \tag{4.56}$$

Then $\mathbf{U} = (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$*, where* $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B$ *(cf. eq. (2.75)). In particular,* $\mathbf{U} = \mathbf{U}_{holo}^{(\mathrm{sym})}$ *as defined behaviorally in Chapter 2 (cf. eq. (2.79)).*

Proof. By hypothesis (4.56), in the X-basis the control-block matrix of $\mathbf{U}$ is

$$\mathbf{B} \;:=\; \frac{1}{2}\begin{bmatrix} \hat{\mathbf{U}}_{+} & \hat{\mathbf{U}}_{-} \\ \hat{\mathbf{U}}_{-} & \hat{\mathbf{U}}_{+} \end{bmatrix}.$$

Define operator-valued blocks (on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$) in this basis by $B_{++} := \mathsf{U}_{+\leftarrow+} = \frac{1}{2}\hat{\mathbf{U}}_{+}$ and $B_{+-} := \mathsf{U}_{+\leftarrow-} = \frac{1}{2}\hat{\mathbf{U}}_{-}$. Then we can *reconstruct the branches* A, B from the RR–spec alone:

$$A \;=\; B_{++} + B_{+-} \;=\; \tfrac{1}{2}(\hat{\mathbf{U}}_{+} + \hat{\mathbf{U}}_{-}), \qquad B \;=\; B_{++} - B_{+-} \;=\; \tfrac{1}{2}(\hat{\mathbf{U}}_{+} - \hat{\mathbf{U}}_{-}). \tag{4.57}$$

Let $\mathbf{D}$ denote the Z-basis diagonal block of the controlled splitter, $\mathbf{D} := \mathrm{diag}(A, B)$, so that $\mathbf{U}_{\mathrm{ctrl}} \leftrightarrow \mathbf{D}$ in $\mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$ (cf. Proposition 4.152 and eq. (4.49)). Changing basis by the Hadamard H_c (cf. Definition 2.119), the conjugation $(H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$ has X-basis block matrix

$$\mathbf{B}' \;=\; \frac{1}{2}\begin{bmatrix} A{+}B & A{-}B \\ A{-}B & A{+}B \end{bmatrix} \overset{(4.57)}{=} \frac{1}{2}\begin{bmatrix} \hat{\mathbf{U}}_{+} & \hat{\mathbf{U}}_{-} \\ \hat{\mathbf{U}}_{-} & \hat{\mathbf{U}}_{+} \end{bmatrix} = \mathbf{B}.$$

Hence $\mathbf{U}$ and $(H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$ have identical RR–matrix families in an orthonormal control basis. By the reconstruction property of partial matrix elements (cf. eq. (4.45)), equality of all control blocks implies equality of the operators on $\mathcal{H}_{\mathrm{Holo}}$. Therefore $\mathbf{U} = (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I)$. □

Remark 4.157 (What Proposition 4.156 does)**.** Proposition 4.156 is the *converse* to Proposition 4.154. While Proposition 4.154 verifies that the implementation word $\mathbf{U}_{\mathrm{sym}} = \mathbf{U}_{\mathrm{Had}}\mathbf{U}_{\mathrm{ctrl}}\mathbf{U}_{\mathrm{Had}}$ realizes the Chapter 2 ± RR–spec (eq. (2.79)), Proposition 4.156 says the *spec alone*—the X-basis block family $\frac{1}{2}\begin{pmatrix} \hat{\mathbf{U}}_{+} & \hat{\mathbf{U}}_{-} \\ \hat{\mathbf{U}}_{-} & \hat{\mathbf{U}}_{+} \end{pmatrix}$—already *determines* the device:

$$\mathbf{U} \;=\; (H_c \otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(H_c \otimes I), \qquad \mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B,$$

with $A = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, $B = \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ and $\hat{\mathbf{U}}_{\pm} = A \pm B$. Thus, specification $\Rightarrow$ unique implementation on $\mathcal{H}_{\mathrm{Holo}}$ (reconstruction via eq. (4.45)), making the symmetric device both *sound* (Proposition 4.154) and *complete* (Proposition 4.156) with respect to the RR–matrix semantics.

Corollary 4.158 (Perfect and partial interference, wordwise criteria)**.** *In the X-basis, perfect constructive (resp. destructive) interference in the $+$ output channel occurs iff $\hat{\mathbf{U}}_- = 0$ (resp. $\hat{\mathbf{U}}_+ = 0$). More generally,*

$$\|\mathsf{W}_{-\leftarrow+}\| \;=\; \tfrac{1}{2}\,\|\hat{\mathbf{U}}_-\|, \qquad \|\mathsf{W}_{+\leftarrow+}\| \;=\; \tfrac{1}{2}\,\|\hat{\mathbf{U}}_+\|, \tag{4.58}$$

with the same relations for the $-$ input by symmetry.

Proof. Work in the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$. By the Hadamard-wrapped interferometer block formulas (Proposition 4.153 and eq. (4.50)) we have, for $+$ input,

$$\mathsf{W}_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_+, \qquad \mathsf{W}_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_-,$$

where $\hat{\mathbf{U}}_{\pm} := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N} \pm \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$ (cf. eq. (2.79)).

Perfect constructive/destructive interference in the $+$ output. In the wordwise semantics, "perfect constructive in the $+$ output channel for $+$ input" means that the $-$ output branch vanishes, i.e. $\mathsf{W}_{-\leftarrow+} = 0$; similarly, "perfect destructive in the $+$ output" means $\mathsf{W}_{+\leftarrow+} = 0$. Using the identities above, these conditions are equivalent to

$$\mathsf{W}_{-\leftarrow+} = 0 \iff \hat{\mathbf{U}}_- = 0, \qquad \mathsf{W}_{+\leftarrow+} = 0 \iff \hat{\mathbf{U}}_+ = 0,$$

which proves the iff statements.

Norm relations. Let $\|\cdot\|$ denote the operator norm on $\mathcal{B}(\mathcal{H}_{\mathrm{RR}}^{(2n)})$ (any absolutely homogeneous norm would suffice). By absolute homogeneity and the block identities,

$$\left\|\mathsf{W}_{-\leftarrow+}\right\| = \left\|\tfrac{1}{2}\,\hat{\mathbf{U}}_-\right\| = \tfrac{1}{2}\,\|\hat{\mathbf{U}}_-\|, \qquad \left\|\mathsf{W}_{+\leftarrow+}\right\| = \left\|\tfrac{1}{2}\,\hat{\mathbf{U}}_+\right\| = \tfrac{1}{2}\,\|\hat{\mathbf{U}}_+\|,$$

which is eq. (4.58).

Symmetry for $-$ input. The remaining relations follow by the same calculation for $-$ input, using again $\mathsf{W}_{+\leftarrow-} = \frac{1}{2}\,\hat{\mathbf{U}}_-$ and $\mathsf{W}_{-\leftarrow-} = \frac{1}{2}\,\hat{\mathbf{U}}_+$ from Proposition 4.153 and eq. (4.50). □

Lemma 4.159 (Asymmetric SU(2) normal form)**.** *Let $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, and set $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B$ (cf. eqs. (2.75) and (4.49) and Proposition 4.152). For any control couplers $U_c^{(L)}, U_c^{(R)} \in U(\mathcal{H}_c)$ define the device word*

$$\mathbf{U}_{\mathrm{asym}} \;:=\; (U_c^{(R)} \otimes I)\;\mathbf{U}_{\mathrm{ctrl}}\;(U_c^{(L)} \otimes I).$$

Then for any orthonormal control basis $\mathcal{B}_c \subset \mathcal{H}_c$ and $\xi, \eta \in \mathcal{B}_c$,

$$\mathsf{W}_{\xi\leftarrow\eta}^{(\mathrm{asym})} \;=\; \langle\xi|U_c^{(R)}|\mathbf{0}\rangle\,\langle\mathbf{0}|U_c^{(L)}|\eta\rangle\,A \;+\; \langle\xi|U_c^{(R)}|\mathbf{1}\rangle\,\langle\mathbf{1}|U_c^{(L)}|\eta\rangle\,B, \tag{4.59}$$

where $\mathsf{W}_{\xi\leftarrow\eta}^{(\mathrm{asym})}$ denotes the RR–matrix element of $\mathbf{U}_{\mathrm{asym}}$ (cf. Definition 4.148 and eq. (4.45)).

Proof. By definition of RR–matrix elements (eq. (4.45)),

$$\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = (\langle\xi|_c\otimes I)\,(U_c^{(R)}\otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(U_c^{(L)}\otimes I)\,(|\eta\rangle_c\otimes I).$$

Insert the Z-basis resolution of the control identity on both sides of $\mathbf{U}_{\mathrm{ctrl}}$, $I_c = |\mathbf{0}\rangle\langle\mathbf{0}| + |\mathbf{1}\rangle\langle\mathbf{1}|$, and use that $\mathbf{U}_{\mathrm{ctrl}}$ is diagonal in this basis with blocks A, B (Proposition 4.152 and eq. (4.49)). This yields

$$\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \langle\xi|U_c^{(R)}|\mathbf{0}\rangle\,\langle\mathbf{0}|U_c^{(L)}|\eta\rangle\,A + \langle\xi|U_c^{(R)}|\mathbf{1}\rangle\,\langle\mathbf{1}|U_c^{(L)}|\eta\rangle\,B,$$

which is eq. (4.59). No properties of A, B beyond their action on $\mathcal{H}_{\mathrm{RR}}^{(2n)}$ are used. □

Remark 4.160 (Specializations and consequences)**.** *(i)* Symmetric interferometer: $U_c^{(L)} = U_c^{(R)} = H_c$ gives the sum/difference blocks $\frac{1}{2}(A \pm B) = \frac{1}{2}\,\hat{\mathbf{U}}_{\pm}$ (Proposition 4.153). *(ii)* Single output coupler: $U_c^{(L)} = I$, $U_c^{(R)} = H_c$ yields $\frac{1}{\sqrt{2}}$ times a single branch in each block (Corollary 4.162). *(iii)* Single input coupler: $U_c^{(L)} = H_c$, $U_c^{(R)} = I$ yields the corrected $\frac{1}{\sqrt{2}}$ pure-branch blocks (Corollary 4.163). *(iv)* General SU(2) phases: arbitrary $U_c^{(L/R)}$ give coefficients $\alpha_{\xi\eta}, \beta_{\xi\eta}$ with the mixing bounds following from block unitarity (Corollary 4.151). *(v)* Equality with Chapter 2: choosing $U_c^{(L/R)}$ to match the Chapter 2 construction gives identical RR blocks and hence identical devices (Proposition 4.165).

Proposition 4.161 (Asymmetric holo-interferometer: general SU(2) couplers)**.** *Let $U_c^{(L)}, U_c^{(R)} \in \mathrm{U}(\mathcal{H}_c)$ be arbitrary control unitaries and define the asymmetric device word*

$$\mathbf{U}_{\mathrm{asym}} \;:=\; (U_c^{(R)}\otimes I)\;\mathbf{U}_{\mathrm{ctrl}}\;(U_c^{(L)}\otimes I),$$

with $\mathbf{U}_{\mathrm{ctrl}}$ as in eq. (2.75) and RR branch operators $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$. For any orthonormal control basis $\mathcal{B}_c$ and $\xi, \eta \in \mathcal{B}_c$,

$$\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} \;=\; \Big\langle\xi\Big|U_c^{(R)}\Big|\mathbf{0}\Big\rangle\,\Big\langle\mathbf{0}\Big|U_c^{(L)}\Big|\eta\Big\rangle\,A \;+\; \Big\langle\xi\Big|U_c^{(R)}\Big|\mathbf{1}\Big\rangle\,\Big\langle\mathbf{1}\Big|U_c^{(L)}\Big|\eta\Big\rangle\,B. \tag{4.60}$$

Proof. This is an immediate consequence of Lemma 4.159. Indeed, with $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, and $\mathbf{U}_{\mathrm{asym}} = (U_c^{(R)}\otimes I)\,\mathbf{U}_{\mathrm{ctrl}}\,(U_c^{(L)}\otimes I)$, Lemma 4.159 gives, for any orthonormal control basis $\mathcal{B}_c$ and $\xi, \eta \in \mathcal{B}_c$,

$$\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \langle\xi|U_c^{(R)}|\mathbf{0}\rangle\,\langle\mathbf{0}|U_c^{(L)}|\eta\rangle\,A + \langle\xi|U_c^{(R)}|\mathbf{1}\rangle\,\langle\mathbf{1}|U_c^{(L)}|\eta\rangle\,B,$$

which is exactly the claimed block formula eq. (4.60). Equivalently, one may derive the same expression directly from the RR–extraction eq. (4.45) by inserting $I_c = |\mathbf{0}\rangle\langle\mathbf{0}| + |\mathbf{1}\rangle\langle\mathbf{1}|$ and using the diagonal form of $\mathbf{U}_{\mathrm{ctrl}}$ in the Z-basis (Proposition 4.152 and eq. (4.49)), but Lemma 4.159 already encapsulates this calculation. □

Corollary 4.162 (Single output coupler)**.** *Let $U_c^{(R)} = H_c$, $U_c^{(L)} = I$. In the computational basis $\mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$,*

$$\begin{aligned} \mathsf{W}^{(\mathrm{asym})}_{\mathbf{0}\leftarrow\mathbf{0}} &= \tfrac{1}{\sqrt{2}}A, \quad \mathsf{W}^{(\mathrm{asym})}_{\mathbf{1}\leftarrow\mathbf{0}} = \tfrac{1}{\sqrt{2}}A, \\ \mathsf{W}^{(\mathrm{asym})}_{\mathbf{0}\leftarrow\mathbf{1}} &= \tfrac{1}{\sqrt{2}}B, \quad \mathsf{W}^{(\mathrm{asym})}_{\mathbf{1}\leftarrow\mathbf{1}} = -\tfrac{1}{\sqrt{2}}B. \end{aligned} \tag{4.61}$$

Thus a single *readout coupler mixes each branch amplitude into two output ports without creating $A \pm B$ interference inside a single block (interference appears when reading in the X-basis).*

Proof. Set $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$. Consider the asymmetric device $\mathbf{U}_{\mathrm{asym}} = (U_c^{(R)} \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (U_c^{(L)} \otimes I)$ with $U_c^{(R)} = H_c$, $U_c^{(L)} = I$ and $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B$ (cf. eq. (2.75)). By the general asymmetric block formula Proposition 4.161 and eq. (4.60), for any $\xi, \eta \in \mathcal{B}_c^{(Z)} = \{|\mathbf{0}\rangle, |\mathbf{1}\rangle\}$,

$$\mathsf{W}_{\xi \leftarrow \eta}^{(\mathrm{asym})} \;=\; \underbrace{\langle \xi | H_c | \mathbf{0} \rangle}_{\text{output coupler}} \; \underbrace{\langle \mathbf{0} | I | \eta \rangle}_{=\,\delta_{\eta,\mathbf{0}}} A \;+\; \underbrace{\langle \xi | H_c | \mathbf{1} \rangle}_{\text{output coupler}} \; \underbrace{\langle \mathbf{1} | I | \eta \rangle}_{=\,\delta_{\eta,\mathbf{1}}} B.$$

Using the standard Hadamard overlaps in the computational basis (cf. Definition 2.119), $\langle \mathbf{0}|H_c|\mathbf{0}\rangle = \langle \mathbf{1}|H_c|\mathbf{0}\rangle = \langle \mathbf{0}|H_c|\mathbf{1}\rangle = \frac{1}{\sqrt{2}}$, $\langle \mathbf{1}|H_c|\mathbf{1}\rangle = -\frac{1}{\sqrt{2}}$, we evaluate the four entries:

(i) Input $\eta = \mathbf{0}$:

$$\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{0}}^{(\mathrm{asym})} = \langle \mathbf{0}|H_c|\mathbf{0}\rangle\, A = \tfrac{1}{\sqrt{2}} A, \qquad \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{0}}^{(\mathrm{asym})} = \langle \mathbf{1}|H_c|\mathbf{0}\rangle\, A = \tfrac{1}{\sqrt{2}} A.$$

(ii) Input $\eta = \mathbf{1}$:

$$\mathsf{W}_{\mathbf{0}\leftarrow\mathbf{1}}^{(\mathrm{asym})} = \langle \mathbf{0}|H_c|\mathbf{1}\rangle\, B = \tfrac{1}{\sqrt{2}} B, \qquad \mathsf{W}_{\mathbf{1}\leftarrow\mathbf{1}}^{(\mathrm{asym})} = \langle \mathbf{1}|H_c|\mathbf{1}\rangle\, B = -\tfrac{1}{\sqrt{2}} B.$$

These are exactly the relations in eq. (4.61). Each RR–block contains a single branch operator (either A or B) scaled by the coupler coefficient; hence no $A \pm B$ interference appears within an individual block in the Z-readout. Interference emerges when reading in the X-basis, where the blocks become sums/differences as in Proposition 4.153 and eq. (4.50). □

Corollary 4.163 (Single input coupler)**.** *Let $U_c^{(R)} = I$, $U_c^{(L)} = H_c$. In the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$,*

$$\mathsf{W}_{+\leftarrow+}^{(\mathrm{asym})} = \tfrac{1}{\sqrt{2}} A, \quad \mathsf{W}_{-\leftarrow+}^{(\mathrm{asym})} = \tfrac{1}{\sqrt{2}} A, \quad \mathsf{W}_{+\leftarrow-}^{(\mathrm{asym})} = \tfrac{1}{\sqrt{2}} B, \quad \mathsf{W}_{-\leftarrow-}^{(\mathrm{asym})} = -\tfrac{1}{\sqrt{2}} B, \tag{4.62}$$

where $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$, $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$. These follow directly from the general asymmetric block formula Proposition 4.161 and eq. (4.60).

Proof. Set $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$. Consider the asymmetric device $\mathbf{U}_{\mathrm{asym}} = (U_c^{(R)} \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (U_c^{(L)} \otimes I)$ with $U_c^{(R)} = I$, $U_c^{(L)} = H_c$ and $\mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B$ (cf. eq. (2.75)). By the general asymmetric block formula Proposition 4.161 and eq. (4.60), for any control basis states $\xi, \eta \in \mathcal{B}_c$,

$$\mathsf{W}_{\xi \leftarrow \eta}^{(\mathrm{asym})} \;=\; \langle \xi | I | \mathbf{0} \rangle\, \langle \mathbf{0} | H_c | \eta \rangle\, A \;+\; \langle \xi | I | \mathbf{1} \rangle\, \langle \mathbf{1} | H_c | \eta \rangle\, B. \tag{4.63}$$

Now choose the X-basis $\mathcal{B}_c^{(X)} = \{|+\rangle, |-\rangle\}$ with $|\pm\rangle = \frac{1}{\sqrt{2}}(|\mathbf{0}\rangle \pm |\mathbf{1}\rangle)$ (cf. Definition 2.119). Using the Hadamard overlaps

$$\langle \mathbf{0}|H_c|+\rangle = 1, \quad \langle \mathbf{1}|H_c|+\rangle = 0, \qquad \langle \mathbf{0}|H_c|-\rangle = 0, \quad \langle \mathbf{1}|H_c|-\rangle = 1,$$

and the X-to-Z overlaps

$$\langle +|\mathbf{0}\rangle = \tfrac{1}{\sqrt{2}}, \quad \langle +|\mathbf{1}\rangle = \tfrac{1}{\sqrt{2}}, \qquad \langle -|\mathbf{0}\rangle = \tfrac{1}{\sqrt{2}}, \quad \langle -|\mathbf{1}\rangle = -\tfrac{1}{\sqrt{2}},$$

we evaluate (4.63) entrywise.

(i) + input ($\eta = +$). Then $\langle \mathbf{0}|H_c|+\rangle = 1$, $\langle \mathbf{1}|H_c|+\rangle = 0$, so

$$\mathsf{W}^{(\mathrm{asym})}_{+\leftarrow+} = \langle +|\mathbf{0}\rangle\, A = \tfrac{1}{\sqrt{2}} A, \qquad \mathsf{W}^{(\mathrm{asym})}_{-\leftarrow+} = \langle -|\mathbf{0}\rangle\, A = \tfrac{1}{\sqrt{2}} A.$$

(ii) − input ($\eta = -$). Then $\langle \mathbf{0}|H_c|-\rangle = 0$, $\langle \mathbf{1}|H_c|-\rangle = 1$, so

$$\mathsf{W}^{(\mathrm{asym})}_{+\leftarrow-} = \langle +|\mathbf{1}\rangle\, B = \tfrac{1}{\sqrt{2}} B, \qquad \mathsf{W}^{(\mathrm{asym})}_{-\leftarrow-} = \langle -|\mathbf{1}\rangle\, B = -\tfrac{1}{\sqrt{2}} B.$$

Thus, with a *single input coupler* $U_c^{(L)} = H_c$ and readout in the X-basis, the RR–matrix elements are

$$\mathsf{W}^{(\mathrm{asym})}_{+\leftarrow+} = \tfrac{1}{\sqrt{2}} A, \quad \mathsf{W}^{(\mathrm{asym})}_{-\leftarrow+} = \tfrac{1}{\sqrt{2}} A, \quad \mathsf{W}^{(\mathrm{asym})}_{+\leftarrow-} = \tfrac{1}{\sqrt{2}} B, \quad \mathsf{W}^{(\mathrm{asym})}_{-\leftarrow-} = -\tfrac{1}{\sqrt{2}} B.$$

Each block contains a *single* branch operator (either A or B) scaled by the appropriate coupler overlap; no $A \pm B$ combination appears within a single block.

Consistency note. The sum/difference blocks $\frac{1}{2}(A \pm B) = \frac{1}{2}\hat{\mathbf{U}}_{\pm}$ of eq. (2.79) arise when the device has *both* input and output Hadamard couplers (the symmetric wrapper of Proposition 4.153) or, equivalently, when one expresses $\mathbf{U}_{\mathrm{ctrl}}$ itself *in the X-basis on both input and output*, i.e. as the change-of-basis conjugate $(H_c \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (H_c \otimes I)$ (cf. Proposition 4.153). With only the input coupler $U_c^{(L)} = H_c$ and $U_c^{(R)} = I$, the X-basis blocks are as computed above. □

Remark 4.164 (Phase- and imbalance-asymmetry)**.** Taking $U_c^{(L)}$ and/or $U_c^{(R)}$ as a general SU(2) beam splitter with an internal phase (e.g. $U_c^{(L)} = R_z(\phi)\, H_c$, $U_c^{(R)} = H_c$) modifies the coefficients in eq. (4.60) so that $\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \alpha_{\xi\eta}(\phi)\, A + \beta_{\xi\eta}(\phi)\, B$, thereby realizing *unequal* path mixing and controlled relative phases. All such variants still obey the block unitarity *mixing bounds* of Corollary 4.151, since $\mathbf{U}_{\mathrm{asym}}$ is unitary on $\mathcal{H}_{\mathrm{Holo}}$.

Proposition 4.165 (Equivalence with Chapter 2 asymmetric model)**.** *Let $\mathbf{U}^{(\mathrm{asym})}_{holo}$ denote the asymmetric holo-interferometer of Chapter 2 (obtained by a single coupler or a phase-imbalanced pair; cf. the constructions surrounding eqs. (2.78) and (2.79)). Choosing $U_c^{(L)}$, $U_c^{(R)}$ to match that construction, the RR–matrix elements computed from eq. (4.60) agree with those of $\mathbf{U}^{(\mathrm{asym})}_{holo}$ for all control transitions. Hence $\mathbf{U}_{\mathrm{asym}} = \mathbf{U}^{(\mathrm{asym})}_{holo}$ on $\mathcal{H}_{\mathrm{Holo}}$.*

Proof. Let $A := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_G B_N}$ and $B := \hat{\mathbf{U}}_{\mathrm{RR}}^{A_N B_G}$, and fix control couplers $U_c^{(L)}, U_c^{(R)} \in \mathrm{U}(\mathcal{H}_c)$ so as to match the Chapter 2 asymmetric construction (single coupler or phase-imbalanced pair; cf. the discussion around eqs. (2.78) and (2.79)). Define the wordwise asymmetric device

$$\mathbf{U}_{\mathrm{asym}} \;:=\; (U_c^{(R)} \otimes I)\; \mathbf{U}_{\mathrm{ctrl}}\; (U_c^{(L)} \otimes I), \qquad \mathbf{U}_{\mathrm{ctrl}} = |\mathbf{0}\rangle\langle\mathbf{0}|_c \otimes A + |\mathbf{1}\rangle\langle\mathbf{1}|_c \otimes B \quad \text{(cf. eq. (2.75))}.$$

Step 1: RR–matrix elements of the wordwise device. By the general asymmetric block formula (Proposition 4.161 and eq. (4.60)), for any orthonormal control basis $\mathcal{B}_c$ and $\xi, \eta \in \mathcal{B}_c$,

$$\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \langle \xi|U_c^{(R)}|\mathbf{0}\rangle\, \langle \mathbf{0}|U_c^{(L)}|\eta\rangle\, A \;+\; \langle \xi|U_c^{(R)}|\mathbf{1}\rangle\, \langle \mathbf{1}|U_c^{(L)}|\eta\rangle\, B. \tag{4.64}$$

Step 2: RR–matrix elements of the Chapter 2 device. Let $\mathbf{U}^{(\mathrm{asym})}_{\mathrm{holo}}$ be the asymmetric holo-interferometer of Chapter 2 with the same choice of input/output couplers $U_c^{(L)}, U_c^{(R)}$

(single Hadamard or a general SU(2) with phases; cf. eq. (2.78)). By the RR extraction rule (eq. (4.45)) and insertion of the control identity $I_c = |\mathbf{0}\rangle\langle\mathbf{0}| + |\mathbf{1}\rangle\langle\mathbf{1}|$ (the control-resolved convolution, Lemma 4.149 and eq. (4.47)), the RR–matrix elements of $\mathbf{U}^{(\mathrm{asym})}_{\mathrm{holo}}$ evaluate to

$$\mathsf{U}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \langle\xi|U_c^{(R)}|\mathbf{0}\rangle\,\langle\mathbf{0}|U_c^{(L)}|\eta\rangle\,A \;+\; \langle\xi|U_c^{(R)}|\mathbf{1}\rangle\,\langle\mathbf{1}|U_c^{(L)}|\eta\rangle\,B, \tag{4.65}$$

i.e. the same operator-valued block formula as (4.64). (This is the standard parallel-path evaluation in Chapter 2; see also the special cases worked out in Corollaries 4.162 and 4.163.)

Step 3: Equality of devices. Comparing (4.64) and (4.65) shows that, for every orthonormal control basis $\mathcal{B}_c$ and every $\xi,\eta\in\mathcal{B}_c$, $\mathsf{W}^{(\mathrm{asym})}_{\xi\leftarrow\eta} = \mathsf{U}^{(\mathrm{asym})}_{\xi\leftarrow\eta}$. By the reconstruction property of partial matrix elements (eq. (4.45)), equality of all control blocks implies equality of the underlying operators on $\mathcal{H}_{\mathrm{Holo}}$. Hence $\mathbf{U}_{\mathrm{asym}} = \mathbf{U}^{(\mathrm{asym})}_{\mathrm{holo}}$.

This establishes the claimed equivalence for arbitrary (single or paired, possibly phase-imbalanced) couplers chosen to match the Chapter 2 asymmetric construction. □

Remarks on internal RR factorization (link to generators). While the wordwise calculus treats the RR branch operators as opaque letters of $\mathsf{A}_{\mathrm{holo}}$, each such operator may internally factor through the parasymmetric blocks of Chapter 2,

$$\begin{aligned}\hat{\mathbf{U}}^{(\cdot)}_{\mathrm{RR}} &\rightsquigarrow U_L\otimes U_P\otimes U_G,\\ U_P &= \exp\Big(i\sum_{i<j} J_{ij}\left(P^{(ij)}_{\mathrm{para}} - P^{(ij)}_{\mathrm{antipara}}\right)\Big).\end{aligned}$$

consistent with the pairwise generator $\hat{F}^{(\mathrm{pair})}_{\mathrm{para}}$ and the composite evolution $U_N^{(\odot)}$ in Chapter 2. Unitarity on $\mathcal{H}_{\mathrm{Holo}}$ then enforces the isometric mixing bounds of Corollary 4.151, which will be invoked in the wordwise kinematics and mixing analysis.

Definition 4.166 (Word-dressed selectors and word-evaluated channels)**.** Let $\hat{\mathcal{F}}_\alpha(y)$ be the Fourfold selectors (Chapter 1) and let $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ be as in (4.45), acting on the RR factor that contains the modal fibre (via the lifted embeddings of Chapter 3; cf. Definition 2.103). Define the *word-dressed selector*

$$\hat{\mathcal{F}}^{[\mathbf{W};\,\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}]}_\alpha(y) := \mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\,\hat{\mathcal{F}}_\alpha(y),$$

and the corresponding *word-evaluated channel*

$$\hat{G}^{\alpha\beta}_\Lambda\Big(x,x';\mathbf{W},\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}\Big) := \Big(\hat{\mathcal{F}}^{[\mathbf{W};\,\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}]}_\alpha(x)\Big)^\dagger\,\mathcal{U}(x\leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x'). \tag{4.66}$$

For $\mathbf{W}=I$ and any control states, this reduces to the undeformed $\hat{G}^{\alpha\beta}_\Lambda(x,x')$ of Definition 4.61.

Proposition 4.167 (Gauge covariance and grading preserved under holosymmetric dressing)**.** *For each* $\mathbf{W}$ *and control pair* $(\chi_{\mathrm{in}},\chi_{\mathrm{out}})$*:*

(a) Gauge covariance
$\hat{G}^{\alpha\beta}_\Lambda(x,x';\mathbf{W},\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}) \mapsto g(x)\,\hat{G}^{\alpha\beta}_\Lambda(\cdots)\,g(x')^\dagger$ *by Proposition 4.54 and Corollary 4.64, since* $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ *is internal to the fibre factor and conjugates compatibly.*

(b) Adjoint and degree

$\big(\hat{G}^{\alpha\beta}_{\Lambda}(\cdots)\big)^{\dagger} = \hat{G}^{\beta\alpha}_{\Lambda}(x', x; \mathbf{W}^{\dagger}, \chi_{\mathrm{in}} \leftarrow \chi_{\mathrm{out}})$ *and* deg *remains* $\deg(\alpha) + \deg(\beta)$ *(Lemmas 4.66 and 4.98 and Definition 4.94).*

(c) Functoriality

Replacing $\mathbf{W}$ *by a product* $\mathbf{W}_2\mathbf{W}_1$ *composes the dressing*

$$\mathsf{W}_{2,\chi_2\leftarrow\chi_1}\,\mathsf{W}_{1,\chi_1\leftarrow\chi_0}.$$

Geometric concatenation still composes via Proposition 4.52.

Proof. Fix a path $\gamma : x' \to x$, indices $\alpha, \beta \in \mathcal{I}$, and a device word $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ with control transition $(\chi_{\mathrm{in}}, \chi_{\mathrm{out}})$. By the wordwise dressing of the Chapter 4 Fourfold channel, define

$$\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}\big) := \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\,\hat{\mathcal{F}}_{\beta}(x'). \tag{4.67}$$

Here, $\mathcal{U}$ is the parallel transporter and $\hat{\mathcal{F}}_{\alpha}$ are the Fourfold selectors (Definition 4.72); $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ is the RR–matrix element of $\mathbf{W}$ (Definition 4.148 and eq. (4.45)).

(a) Gauge covariance. Under a gauge change $g(\cdot)$ on the bundle, the factors transform by endpoint conjugation

$$\hat{\mathcal{F}}_{\alpha}(x) \mapsto g(x)\hat{\mathcal{F}}_{\alpha}(x), \qquad \mathcal{U}(x \leftarrow x'; \gamma) \mapsto g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\,g(x')^{\dagger} \quad (\textit{Proposition 4.54}),$$

and the assembled Fourfold channel obeys endpoint conjugation (*Corollary 4.64*). The RR–matrix element $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ acts on the RR fibre and is *gauge–neutral* with respect to the base change on $\mathscr{H}_{(0,1)}$. Thus, applying the transformations inside (4.67) and canceling $g(x)^{\dagger}g(x) = I$ and $g(x')^{\dagger}$ across the neutral RR factor, we obtain

$$\hat{G}^{\alpha\beta}_{\Lambda}(\cdots) \;\longmapsto\; g(x)\;\hat{G}^{\alpha\beta}_{\Lambda}(\cdots)\;g(x')^{\dagger},$$

which is the asserted covariance.

(b) Adjoint and degree. Taking adjoints in (4.67) and using $\mathcal{U}(x \leftarrow x'; \gamma)^{\dagger} = \mathcal{U}(x' \leftarrow x; \gamma^{-1})$ and $(\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}})^{\dagger} = \mathsf{W}^{\dagger}_{\chi_{\mathrm{in}}\leftarrow\chi_{\mathrm{out}}}$ (from *eq.* (4.45) and the adjoint rule), we get

$$\big(\hat{G}^{\alpha\beta}_{\Lambda}(x, x'; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}})\big)^{\dagger} = \hat{\mathcal{F}}^{\dagger}_{\beta}(x')\;\mathcal{U}(x' \leftarrow x; \gamma^{-1})\;\mathsf{W}^{\dagger}_{\chi_{\mathrm{in}}\leftarrow\chi_{\mathrm{out}}}\;\hat{\mathcal{F}}_{\alpha}(x),$$

which is exactly $\hat{G}^{\beta\alpha}_{\Lambda}(x', x; \mathbf{W}^{\dagger}, \chi_{\mathrm{in}} \leftarrow \chi_{\mathrm{out}})$, in accordance with the Hermitian symmetry of channels (*Lemma 4.66*).

For the grading, recall that the dialectic degree is carried by the selector labels and composes additively (*Definition 4.94and Lemma 4.98*). The dressed factor $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ acts in the RR fibre and is of degree 0 in the dialectic grading; hence

$$\deg\big(\hat{G}^{\alpha\beta}_{\Lambda}(\cdots)\big) = \deg\big(\hat{\mathcal{F}}^{\dagger}_{\alpha}\big) + \deg\big(\hat{\mathcal{F}}_{\beta}\big) = \deg(\alpha) + \deg(\beta),$$

as claimed.

(c) Functoriality. Let $\mathbf{W} = \mathbf{W}_2\mathbf{W}_1$. Then, by (4.67),

$$\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; \mathbf{W}, \chi_2 \leftarrow \chi_0\big) = \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\, \mathcal{U}(x \leftarrow x'; \gamma) \Big(\sum_{\chi_1} \mathsf{W}_{2,\chi_2\leftarrow\chi_1}\, \mathsf{W}_{1,\chi_1\leftarrow\chi_0} \Big)\, \hat{\mathcal{F}}_{\beta}(x'),$$

where the sum over the intermediate control index χ_1 is the control-resolved convolution (*Lemma* 4.149*and eq.* (4.47)). Thus the dressing composes by $\mathsf{W}_{2,\chi_2\leftarrow\chi_1}\, \mathsf{W}_{1,\chi_1\leftarrow\chi_0}$ as stated.

For geometric concatenation of paths $\gamma_2 : x'' \to x$, $\gamma_1 : x' \to x''$, one has $\mathcal{U}(x \leftarrow x'; \gamma_2 \star \gamma_1) = \mathcal{U}(x \leftarrow x''; \gamma_2)\, \mathcal{U}(x'' \leftarrow x'; \gamma_1)$ by functoriality of transport (*Proposition* 4.52). Inserting this into (4.67) shows that the geometric composition of segments and the algebraic composition of dressings factorize compatibly, proving functoriality.

Items (a)–(c) together establish Proposition 4.167. □

Corollary 4.168 (Sum/difference words from Hadamard conjugation)**.** *With* $\mathbf{W} = \mathbf{U}_{\mathrm{Had}}$ *(Definition 2.119 and eq.* (2.78)*) and* $|\chi_{\mathrm{in}}\rangle = |\chi_{\mathrm{out}}\rangle \in \{|+\rangle, |-\rangle\}$*, the RR matrix elements are respectively the* sum *and* difference *of the two parallel RR paths (eq.* (2.79)*). The induced channels* $\hat{G}^{\alpha\beta}_{\Lambda}(x, x'; \mathbf{U}_{\mathrm{Had}}, \chi \leftarrow \chi)$ *therefore register holosymmetric interference between alternative mechanisms in the sense of Chapter 3.*

Proof. Let $A := \hat{\mathbf{U}}^{A_G B_N}_{\mathrm{RR}}$ and $B := \hat{\mathbf{U}}^{A_N B_G}_{\mathrm{RR}}$, and set $\hat{\mathbf{U}}_{\pm} := A \pm B$ (cf. eq. (2.79)). Take $\mathbf{W} = \mathbf{U}_{\mathrm{Had}} = (H_c \otimes I)\, \mathbf{U}_{\mathrm{ctrl}}\, (H_c \otimes I)$ (Definition 2.119 and eq. (2.78)). By the Hadamard-wrapped block identities (Proposition 4.153 and eq. (4.50)), for $\chi \in \{+, -\}$ we have

$$\mathsf{W}_{+\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{+}, \qquad \mathsf{W}_{-\leftarrow+} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{-}, \qquad \mathsf{W}_{+\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{-}, \qquad \mathsf{W}_{-\leftarrow-} = \tfrac{1}{2}\,\hat{\mathbf{U}}_{+}.$$

Thus, when $|\chi_{\mathrm{in}}\rangle = |\chi_{\mathrm{out}}\rangle = |+\rangle$ (resp. $|-\rangle$), the RR element is proportional to the *sum* (resp. *difference*) of the two parallel RR paths ($\hat{\mathbf{U}}_{+}$ resp. $\hat{\mathbf{U}}_{-}$), as stated.

For the induced channels, recall the wordwise dressing definition

$$\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}\big) := \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\, \hat{\mathcal{F}}_{\beta}(x') \quad \text{(cf. eq. (4.67))}. \tag{4.68}$$

By linearity in the RR factor, inserting the above RR elements gives, for example,

$$\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; \mathbf{U}_{\mathrm{Had}}, + \leftarrow +\big) = \tfrac{1}{2}\Big(\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; A, + \leftarrow +\big) \;+\; \hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; B, + \leftarrow +\big)\Big),$$

and similarly

$$\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; \mathbf{U}_{\mathrm{Had}}, - \leftarrow +\big) = \tfrac{1}{2}\Big(\hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; A, - \leftarrow +\big) \;-\; \hat{G}^{\alpha\beta}_{\Lambda}\big(x, x'; B, - \leftarrow +\big)\Big),$$

with the analogous relations for $-$ input. Hence the channels produced by $\mathbf{U}_{\mathrm{Had}}$ are *sum/difference* combinations of the channels associated to the two parallel RR mechanisms. By Proposition 4.167(a,b), these dressed channels inherit gauge covariance and Hermitian/degree structure; the $\pm$ superpositions therefore *register holosymmetric interference* between the alternatives in the precise wordwise sense (constructive in the $+$ block, destructive in the $-$ block), as advertised in Chapter 3.

This proves Corollary 4.168. □

Theorem 4.169 (Central (or approximately central) holosymmetry — words version)**.** *Let* G *be the* $*$*-algebra generated by holosymmetric channel words in Section 4.2, with alphabet* $\Sigma := \{\hat{\mathcal{F}}_\alpha(x), \hat{\mathcal{F}}_\alpha^\dagger(x),\ \mathcal{U}(x \leftarrow x';\gamma)\}$ *as in Definitions 4.48 and 4.61 and block composition through intermediate loci (Proposition 4.85). Define the holosymmetric self-channel*

$$\hat{G}_\Lambda^{ss}(x,x') := \hat{\mathcal{F}}_s^\dagger(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x').$$

Assume any one of the following endogenous hypotheses:

(C1$^{\text{word}}$) Control/branch transitivity. *The inner automorphism group* $\mathcal{H}$ *generated by control-basis rotations* $\mathbf{U}_c \in \mathrm{SU}(2)$ *(as in the holosymmetric interferometers, Definitions 2.119, 2.123 and 2.124) and the branch-swap involution* $\sigma : A_G B_N \leftrightarrow A_N B_G$ *on path families (Definition 2.108) acts by conjugation on* G*, and its representation is (nearly) irreducible on each typed Hom-space of words (Remark 4.140). Moreover,* $\hat{G}_\Lambda^{ss}$ *is* $\mathcal{H}$*-invariant (basis-independent and swap-symmetric; cf. the commutator-lensing normal form and effect equality in Definition 3.12, eq. (3.46), and Corollary 3.22).*

(C2$^{\text{word}}$) Flat holosymmetric section. *There exists a gauge in which* $\hat{\mathcal{F}}_s$ *is parallel along admissible paths, i.e.* $\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x') = \mathrm{e}^{i\phi(x,x';\gamma)}\,\hat{\mathcal{F}}_s(x)$ *for all* γ *joining* x' *to* x *(up to a scalar phase), cf. Definitions 4.48 and 4.49 and Proposition 4.54.*

(C3$^{\text{word}}$) Conditional expectation onto holosymmetric invariants. *There is a contractive, completely positive, idempotent map* $\mathbb{E} : \mathsf{G} \to \mathsf{G}$ *(a Reynolds operator) obtained by averaging over the control-basis group and the branch-swap (cf. Definitions 2.119 and 2.123 for control actions and Definition 2.108 for swap), such that* $\mathbb{E}$ *projects onto the* $\mathcal{H}$*-fixed subalgebra and* $\hat{G}_\Lambda^{ss} \in \operatorname{Ran}\mathbb{E}$*.*

Then for all $X \in \mathsf{G}$*,*

$$[\,\hat{G}_\Lambda^{ss}(x,x'),\,X\,] = 0.$$

If the corresponding hypothesis holds only approximately (e.g. the $\mathcal{H}$*-action is nearly irreducible, or the parallel-transport condition in* (C2$^{\text{word}}$) *holds up to a phase defect* ε*, or* $\mathbb{E}$ *is computed with numerical/structural tolerance* δ*), then there exists* $\Delta \geq 0$ *(the* centrality defect*) such that*

$$\sup_{\|X\|=1} \left\|[\,\hat{G}_\Lambda^{ss},\,X\,]\right\| \;\leq\; \Delta, \qquad \Delta \to 0 \text{ as the defect parameters } \varepsilon,\delta \to 0.$$

Proof. We argue case by case, using only the holosymmetric word architecture.

Generator test. Since G is generated by the alphabet Σ (Definitions 4.48 and 4.61) and closed under block composition through intermediate loci (Proposition 4.85), it suffices to show $[\,\hat{G}_\Lambda^{ss},\,Y\,] = 0$ for each generator $Y \in \Sigma$; the general case follows by induction on word length and the typing/composition rules (Remark 4.140 and Proposition 4.85).

(C1$^{\text{word}}$): Control/branch transitivity. Let $\mathcal{H}$ be the inner automorphism group generated by (i) conjugations by holosymmetric control unitaries $(U_c \otimes I_{\mathrm{RR}})$ (prep/read rotations, Definitions 2.119 and 2.124), and (ii) the branch-swap σ that interchanges the path families $(A_G B_N) \leftrightarrow (A_N B_G)$ (Definition 2.108). By the interferometric constructions (Definition 3.12 and Corollary 3.22), the holosymmetric effects (and hence $\hat{G}_\Lambda^{ss}$ as a word) are basis-independent and swap-symmetric, so $\mathrm{Ad}_h(\hat{G}_\Lambda^{ss}) = \hat{G}_\Lambda^{ss}$ for all $h \in \mathcal{H}$. Let ρ be the (nearly) irreducible representation of $\mathcal{H}$ on a typed Hom-space of words (Remark 4.140). By the fixed-point/Schur argument, the $\mathcal{H}$-invariant elements in that space are scalars, so $\hat{G}_\Lambda^{ss}$ commutes with every

generator Y of matching type. Since G is the sum of such typed Hom-spaces, $\hat{G}^{ss}_{\Lambda}$ commutes with every generator, hence with every word. In the near-irreducible case, the fixed point is within operator-norm Δ of a scalar, giving the uniform defect bound.

(C2$^{\text{word}}$): Flat holosymmetric section. In the parallel gauge (Definition 4.48 and Proposition 4.54), $\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x') = \mathrm{e}^{i\phi}\hat{\mathcal{F}}_s(x)$ for all admissible γ. Then

$$\hat{G}^{ss}_{\Lambda}(x,x') = \hat{\mathcal{F}}^{\dagger}_s(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x') = \mathrm{e}^{i\phi(x,x';\gamma)}\,\hat{\mathcal{F}}^{\dagger}_s(x)\hat{\mathcal{F}}_s(x).$$

The right-hand side is a scalar phase times the endpoint word $\hat{\mathcal{F}}^{\dagger}_s(x)\hat{\mathcal{F}}_s(x)$, which acts as the identity on the s-typed range and annihilates orthogonal types (typing/orthogonality in Remark 4.140). Consequently $\hat{G}^{ss}_{\Lambda}$ acts as a scalar on each typed block and hence commutes with (i) endpoint selectors (Definition 4.61) and (ii) transports $\mathcal{U}(\cdot)$; the phase is central and block composition is admissible (Proposition 4.85). Thus $[\,\hat{G}^{ss}_{\Lambda},\,Y\,]=0$ for all generators Y, hence for all words. If flatness holds up to a phase defect ε, the commutator norm is $O(\varepsilon)$ uniformly in $\|X\|=1$ (Proposition 4.54 and Corollary 4.64).

(C3$^{\text{word}}$): Conditional expectation onto invariants. Define the Reynolds operator

$$\mathbb{E}(Y) \;:=\; \int_{\mathrm{SU}(2)} (U_c\otimes I)^{\dagger}\,Y\,(U_c\otimes I)\,d\mu(U_c) \quad\text{and}\quad \mathbb{E}_{\sigma}(Y) \;:=\; \tfrac{1}{2}\Big(Y+\sigma(Y)\Big),$$

and set $\mathbb{E} := \mathbb{E}_{\sigma}\circ\mathbb{E}$ (Definitions 2.108, 2.119 and 2.123 for the actions averaged). Then $\mathbb{E}$ is a contractive, CP, idempotent conditional expectation onto the $\mathcal{H}$-fixed subalgebra. By control-basis independence and swap symmetry of the holosymmetric effect (Definition 3.12 and Corollary 3.22), $\hat{G}^{ss}_{\Lambda}$ is $\mathcal{H}$-fixed, hence $\hat{G}^{ss}_{\Lambda} = \mathbb{E}(\hat{G}^{ss}_{\Lambda}) \in \operatorname{Ran}\mathbb{E}$. For any generator Y, invariance of the range implies $(U^{\dagger}YU)$ commutes with $\mathbb{E}(Z)$ for all $U\in\mathcal{H}$, and averaging yields $[\,\mathbb{E}(Z),Y\,]=0$. Taking $Z=\hat{G}^{ss}_{\Lambda}$ shows that $\hat{G}^{ss}_{\Lambda}$ commutes with every generator, hence with every word. If the averaging is approximate with tolerance δ, we obtain the uniform bound.

In all three cases we have $[\,\hat{G}^{ss}_{\Lambda},\,Y\,]=0$ for the alphabet generators Y (Definitions 4.48 and 4.61), hence $[\,\hat{G}^{ss}_{\Lambda},\,X\,]=0$ for all words $X\in\mathsf{G}$ by closure under composition (Proposition 4.85). The approximate variants give the stated operator-norm defect bound. □

Theorem 4.170 (Nilpotent p–s edge — words version)**.** *Let G be the $*$-algebra generated by holosymmetric channel words (Section 4.2), with letters $\hat{G}^{\alpha\beta}_{\Lambda}(x_j,x_{j-1}) = \hat{\mathcal{F}}^{\dagger}_{\alpha}(x_j)\,\mathcal{U}(x_j \leftarrow x_{j-1};\gamma_j)\,\hat{\mathcal{F}}_{\beta}(x_{j-1})$ from Definitions 4.48, 4.49 and 4.61, typed and composed through intermediate loci as in Definition 4.141, Proposition 4.85, and Remark 4.140. Define $\hat{G}^{ps}_{\Lambda},\hat{G}^{sp}_{\Lambda}$ with fixed endpoints (x,x').*

Assume any one of the following endogenous hypotheses:

- (N1$^{\text{word}}$) Typing prohibition at the edge. *For each admissible locus y, the mixed composition is ill-typed and vanishes: $\hat{\mathcal{F}}_s(y)\,\hat{\mathcal{F}}^{\dagger}_p(y)=0$, by the domain/codomain typing of words (Remark 4.140 and Proposition 4.85).*
- (N2$^{\text{word}}$) Orthogonality at an intermediate locus. *There exists y with $\hat{\mathcal{F}}^{\dagger}_s(y)\hat{\mathcal{F}}_p(y)=0$ and a dialectically complete resolution at y (Definition 4.84 and Proposition 4.85).*
- (N3$^{\text{word}}$) Spectral support exit. *With the regulated fibre at y given by $E^{(y)}([0,\lambda_{\text{cutoff}}])$ (eq. (4.303)), a $p\to s$ step maps into $\operatorname{Ran}(I-E^{(y)})$ while a subsequent $p\to s$ requires domain $\operatorname{Ran}(E^{(y)})$.*

Then

$$(\hat{G}^{ps}_{\Lambda})^2 = (\hat{G}^{sp}_{\Lambda})^2 = 0.$$

The conclusion is stable under endpoint gauge conjugation $X \mapsto g(x)\, X\, g(x')^\dagger$ by Proposition 4.54 and Corollary 4.64.

Proof. Square expansion and the kill term. For fixed endpoints (x, x'),

$$(\hat{G}^{ps}_{\Lambda})^2 = \hat{\mathcal{F}}^\dagger_p(x)\,\mathcal{U}(x \leftarrow y;\gamma_1)\,\hat{\mathcal{F}}_s(y)\;\hat{\mathcal{F}}^\dagger_p(y)\,\mathcal{U}(y \leftarrow x';\gamma_2)\,\hat{\mathcal{F}}_s(x') \tag{4.69}$$

$$= \hat{\mathcal{F}}^\dagger_p(x)\,\mathcal{U}(x \leftarrow y;\gamma_1)\,\underbrace{\big(\hat{\mathcal{F}}_s(y)\hat{\mathcal{F}}^\dagger_p(y)\big)}_{\text{kill term}}\,\mathcal{U}(y \leftarrow x';\gamma_2)\,\hat{\mathcal{F}}_s(x'). \tag{4.70}$$

(N1$^{\text{word}}$). By the word typing rule (Remark 4.140) implemented via block composition (Proposition 4.85), $\hat{\mathcal{F}}_s(y)\hat{\mathcal{F}}^\dagger_p(y) = 0$. Hence (4.70) gives $(\hat{G}^{ps}_{\Lambda})^2 = 0$. The *sp* case is identical with $p \leftrightarrow s$.
(N2$^{\text{word}}$). Insert a dialectically complete resolution at y (Definition 4.84) to write

$$\hat{G}^{ps}_{\Lambda}(x, x') = \sum_{\gamma \in \mathcal{I}} \hat{G}^{p\gamma}_{\Lambda}(x, y)\, \hat{G}^{\gamma s}_{\Lambda}(y, x').$$

Squaring produces middle factors of the form $\hat{G}^{\gamma s}_{\Lambda}(y, x')\, \hat{G}^{p\delta}_{\Lambda}(x, y)$ which, when expanded back to selectors/transports, carry either $\hat{\mathcal{F}}^\dagger_s(y)\hat{\mathcal{F}}_p(y)$ or its adjoint at y—both zero by hypothesis. Thus each summand vanishes and $(\hat{G}^{ps}_{\Lambda})^2 = 0$; same for *sp*.
(N3$^{\text{word}}$). Insert $\mathbf{1} = E^{(y)} + [I - E^{(y)}]$ between the two *ps* factors. By the support-exit rule, the image of the first *ps* sits in $\mathrm{Ran}(I - E^{(y)})$, while the second *ps* requires domain in $\mathrm{Ran}(E^{(y)})$, so their composition is zero on the regulated fibre (eq. (4.303)). Hence $(\hat{G}^{ps}_{\Lambda})^2 = 0$ and similarly for *sp*.

Gauge stability. Endpoint conjugation preserves zero operators and the hypotheses (Proposition 4.54 and Corollary 4.64), so the conclusion is gauge-invariant. □

Remark 4.171 (Optional grading overlay)**.** If you retain the $\mathbb{Z}_2^2$ overlay (Definition 4.94 and Lemma 4.98), the words above also satisfy $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1, 0)$ and $\deg\big((\hat{G}^{ps})^2\big) = \deg\big((\hat{G}^{sp})^2\big) = (0, 0)$, consistent with nilpotency. The proof itself, however, does not use grading.

Definition 4.172 (Nilpotency defect)**.** Define $\eta := \max\Big\{\|(\hat{G}^{ps}_{\Lambda})^2\|,\ \|(\hat{G}^{sp}_{\Lambda})^2\|\Big\}$. Under approximate forms of (N1$^{\text{word}}$)–(N3$^{\text{word}}$) (typing leakage, small orthogonality error, or imperfect spectral separation), η quantifies the deviation from exact nilpotency.

Theorem 4.173 (Bosonic compatibility in the 0–*s* sector — words version)**.** *Let G be the $*$-algebra of holosymmetric channel words (Section 4.2), generated by letters $\hat{G}^{\alpha\beta}_{\Lambda}(x_j, x_{j-1}) = \hat{\mathcal{F}}^\dagger_\alpha(x_j)\,\mathcal{U}(x_j \leftarrow x_{j-1};\gamma_j)\,\hat{\mathcal{F}}_\beta(x_{j-1})$ (Definitions 4.48, 4.49 and 4.61), typed and composed through intermediate loci (Definition 4.141, Proposition 4.85, and Remark 4.140).*

Define the diagonal self-channels at fixed endpoints (x, x'):

$$\hat{G}^{00}_{\Lambda}(x, x') = \hat{\mathcal{F}}^\dagger_0(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_0(x'), \qquad \hat{G}^{ss}_{\Lambda}(x, x') = \hat{\mathcal{F}}^\dagger_s(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_s(x').$$

Assume any one of the following endogenous hypotheses:

- (B1$^{\text{word}}$) Common spectral generator (functional calculus). *There exists a spectral operator $\hat{D}$ (Chapter IV; Definition 4.341 and eq. (4.159)) and Borel functions f_{00}, f_{ss} such that $\hat{G}^{00}_{\Lambda} = f_{00}(\hat{D})$ and $\hat{G}^{ss}_{\Lambda} = f_{ss}(\hat{D})$ (on the relevant typed Hom-space).*
- (B2$^{\text{word}}$) Parallel diagonals on a flat patch. *On a simply connected neighbourhood with $\mathcal{F} = 0$ (Proposition 4.59), there exists a gauge (endpoint conjugation; Proposition 4.54 and Corollary 4.64) such that, for all admissible paths, $\mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_{\alpha}(x') = \mathrm{e}^{i\phi_{\alpha}(x,x';\gamma)}\, \hat{\mathcal{F}}_{\alpha}(x)$ for $\alpha \in \{0, s\}$. Equivalently (Corollary 4.146), the transporter collapses to a phase and both diagonals reduce to endpoint words.*
- (B3$^{\text{word}}$) Pinching onto the $0/s$ diagonal subalgebra. *Let $P_{\alpha}(x) := \hat{\mathcal{F}}^{\dagger}_{\alpha}(x)\hat{\mathcal{F}}_{\alpha}(x)$ and similarly at x'. The completely positive, contractive, idempotent map*

$$\Pi(Y) \;:=\; \sum_{\alpha\in\{0,s\}} \sum_{\beta\in\{0,s\}} \Big(P_{\alpha}(x)\, Y\, P_{\beta}(x') \Big)$$

maps G onto the commutative C^*-subalgebra generated by $\{P_0(x), P_s(x)\}$ at x and $\{P_0(x'), P_s(x')\}$ at x', and $\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}$ lie in $\operatorname{Ran}\Pi$ (are fixed points).

Then, for all x, x',

$$[\, \hat{G}^{00}_{\Lambda}(x, x'),\, \hat{G}^{ss}_{\Lambda}(x, x')\,] = 0.$$

The conclusion is stable under endpoint conjugation $X \mapsto g(x)\, X\, g(x')^{\dagger}$ by Proposition 4.54 and Corollary 4.64.

Proof. Generator/word reduction. By Proposition 4.85 and the typing rules (Remark 4.140), it suffices to argue at the level of the diagonal self-channels defined above; commutation for these generators propagates to all words built from them and compatible letters.

(B1$^{\text{word}}$). If $\hat{G}^{00}_{\Lambda} = f_{00}(\hat{D})$ and $\hat{G}^{ss}_{\Lambda} = f_{ss}(\hat{D})$ for the same self-adjoint $\hat{D}$ (Definition 4.341), then functional calculus implies $[\, f_{00}(\hat{D}), f_{ss}(\hat{D})\,] = 0$. Hence $[\, \hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}\,] = 0$.

(B2$^{\text{word}}$). On a flat patch, choose a parallel gauge (Propositions 4.54 and 4.59) so that

$$\hat{G}^{00}_{\Lambda}(x, x') = \mathrm{e}^{i\phi_0(x,x';\gamma)}\, P_0(x), \qquad \hat{G}^{ss}_{\Lambda}(x, x') = \mathrm{e}^{i\phi_s(x,x';\gamma)}\, P_s(x).$$

By channel alphabet orthogonality/typing (Remark 4.140), $P_0(x)$ and $P_s(x)$ are endpoint projectors onto orthogonal modal subspaces, hence $P_0(x)P_s(x) = P_s(x)P_0(x) = 0$, and they commute. Phases are scalar, so $[\, \hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}\,] = 0$. Gauge covariance (Proposition 4.54 and Corollary 4.64) preserves commutators, so the result holds in any gauge.

(B3$^{\text{word}}$). The map Π is a conditional expectation (Reynolds operator) onto a *commutative* diagonal subalgebra (the "pinching" onto the $0/s$ blocks at both ends). Since $\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}$ are 0–0 and s–s diagonals respectively, they are fixed by Π, i.e. lie in $\operatorname{Ran}\Pi$. Any two elements of a commutative range commute, hence $[\, \hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}\,] = 0$. Endpoint conjugation preserves $\operatorname{Ran}\Pi$ and commutators, so the conclusion is gauge-stable. □

Remark 4.174 (Optional grading overlay)**.** If you keep the $\mathbb{Z}_2^2$ bookkeeping, then $\deg(\hat{G}^{00}) = \deg(\hat{G}^{ss}) = (0, 0)$ (Definition 4.94), and by Lemma 4.95 one has $[A, B]_{\mathrm{gr}} = [A, B]$ for even A. Thus the graded and ordinary commutators coincide here. The proof above, however, does not use grading.

Definition 4.175 (Bosonic-commutation defect)**.** Under approximate forms of (B1$^{\mathrm{word}}$)–(B3$^{\mathrm{word}}$) (e.g. imperfect shared functional calculus, non-flat phase leakage, or imperfect pinching), define

$$\zeta \;:=\; \big\| [\, \hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda} \,] \big\|.$$

Then $\zeta = 0$ in the exact hypotheses and $\zeta \to 0$ as the defect parameters vanish.

4.2.1 Wordwise Meta-Claim, Compliance Vector, and Geometric Leverage

Proposition 4.176 (Words-only derivability of the trio)**.** *Within the holosymmetric words framework (Section 4.2, Definitions 4.48, 4.61 and 4.141, Propositions 4.85 and 4.143, and Remark 4.140), assume the endogenous hypothesis families*

$$\begin{aligned} &(\mathrm{C1}^{\mathrm{word}})\text{–}(\mathrm{C3}^{\mathrm{word}}) && \textit{(Theorem 4.169)},\\ &(\mathrm{N1}^{\mathrm{word}})\text{–}(\mathrm{N3}^{\mathrm{word}}) && \textit{(Theorem 4.170)},\\ &(\mathrm{B1}^{\mathrm{word}})\text{–}(\mathrm{B3}^{\mathrm{word}}) && \textit{(Theorem 4.173)}. \end{aligned}$$

Then, for all admissible endpoints (x, x') and all channel words $X \in \mathsf{G}$,

(a) Central holosymmetry
$[\, \hat{G}^{ss}_{\Lambda}(x, x'),\, X \,] = 0.$

(b) Nilpotent *p*–*s* edge
$(\hat{G}^{ps}_{\Lambda})^2 = (\hat{G}^{sp}_{\Lambda})^2 = 0.$

(c) Bosonic 0–*s* compatibility
$[\, \hat{G}^{00}_{\Lambda}(x, x'),\, \hat{G}^{ss}_{\Lambda}(x, x') \,] = 0.$

All three statements are invariant under endpoint conjugation $X \mapsto g(x)\, X\, g(x')^{\dagger}$ by Proposition 4.54 and Corollary 4.64.

Remark 4.177 (Optional grading overlay)**.** If the $\mathbb{Z}_2^2$ overlay is retained (Definition 4.94 and Lemma 4.98), then (i) $\deg(\hat{G}^{ss}) = (0,0)$ implies $[A, \cdot]_{\mathrm{gr}} = [A, \cdot]$ by Lemma 4.95; (ii) $\deg(\hat{G}^{ps}) = \deg(\hat{G}^{sp}) = (1,0)$ is consistent with nilpotency and gauge covariance; (iii) $\deg(\hat{G}^{00}) = (0,0)$ and (i) give $[\hat{G}^{00}, \hat{G}^{ss}]_{\mathrm{gr}} = [\hat{G}^{00}, \hat{G}^{ss}] = 0$. The proofs of Theorems 4.169, 4.170 and 4.173 do not use grading.

Definition 4.178 (Holosymmetric compliance vector)**.** Let the *centrality defect* Δ be as in Definition 4.112, the *nilpotency defect* η as in Definition 4.172, and the *bosonic commutation defect* ζ as in Definition 4.175. Define the *holosymmetric compliance vector*

$$\mathfrak{K} \;:=\; (\Delta,\ \eta,\ \zeta) \;\in\; \mathbb{R}^3_{\geq 0}.$$

It is gauge-invariant under endpoint conjugation and vanishes iff the trio in Proposition 4.176 holds exactly.

Definition 4.179 (Operational signatures)**.** Using Chapter III interferometers and lensing (Definitions 2.119, 2.123, 2.124 and 3.12, Corollary 3.22, and eqs. (3.1) and (3.2)), define:

(i) **Visibility envelope width:** For a family of control unitaries $U_c \in \mathrm{SU}(2)$,

$$\mathcal{W}_{\mathrm{vis}} \;:=\; \sup_{U_c} \Big|\, \mathcal{V}(U_c) - \mathcal{V}(I) \,\Big|,$$

where $\mathcal{V}$ is the fringe visibility in the chosen model (eq. (3.2) and its asymmetric analogue).

(ii) **Lensing equality residual:**

$$\mathcal{L}_{\mathrm{res}} \;:=\; \Big\| \; E^{(+\!\to\!+)}_{\mathrm{Holo}} \;-\; E^{(-\!\to\!-)}_{\mathrm{Holo}} \; \Big\|,$$

with $E^{(\cdot)}_{\mathrm{Holo}}$ the lensing effects (Corollary 3.22).

(iii) **Two-step ps amplitude:**

$$\mathcal{A}^{(2)}_{ps} \;:=\; \Big\| \, (\hat{G}^{ps}_{\Lambda})^2 \, \Big\|, \qquad \mathcal{A}^{(2)}_{sp} \;:=\; \Big\| \, (\hat{G}^{sp}_{\Lambda})^2 \, \Big\|.$$

(iv) **Diagonal pinching mismatch:** Let Π be the diagonal pinching onto the $0/s$ subalgebra (Theorem 4.173, case (B3$^{\mathrm{word}}$)). For any observable Y formed from diagonal words,

$$\mathcal{P}_{\mathrm{mis}}(Y) \;:=\; \Big\| \, Y - \Pi(Y) \, \Big\|.$$

Lemma 4.180 (Pinching stability under almost-commutation)**.** *Let $\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}$ be the $(0/s)$ diagonal blocks of the Fourfold channel (Definition 4.81), and let Π denote the diagonal pinching onto the $(0/s)$ block subalgebra (as used in Definition 4.179, cf. the commuting case in* (B3$^{\mathrm{word}}$) *of Theorem 4.173). Set the* bosonic-commutation defect $\zeta := \|[\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}]\|$ *(Definition 4.175). Then there exists an absolute constant $C > 0$ such that for every observable Y generated by $(0/s)$–diagonal words one has*

$$\| \, Y - \Pi(Y) \, \| \;\le\; C \, \zeta.$$

In particular, if $\zeta = 0$ then Π is a conditional expectation onto the $(0/s)$ diagonal subalgebra and $\|Y - \Pi(Y)\| = 0$ for all such Y.

Proof. When $[\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}] = 0$, the $(0/s)$ diagonal algebra is a commuting von Neumann subalgebra and Π is the conditional expectation onto it, so $Y = \Pi(Y)$ for all $(0/s)$–diagonal Y — this is precisely the content of the commuting case in Theorem 4.173.

For the almost-commuting case, represent Π as a double operator integral (DOI) with respect to the spectral measures of $\hat{G}^{00}_{\Lambda}$ and $\hat{G}^{ss}_{\Lambda}$. Standard DOI bounds imply Lipschitz-type stability: if the DOI kernel has bounded divided differences (true for the pinching kernel), then $\|Y - \Pi(Y)\| \le C \, \|[\hat{G}^{00}_{\Lambda}, \hat{G}^{ss}_{\Lambda}]\|$ for a universal $C > 0$. Since the defect ζ is gauge-invariant and norms are preserved under endpoint gauge (Proposition 4.54 and Corollary 4.64), the bound $\|Y - \Pi(Y)\| \le C \, \zeta$ holds uniformly for all $(0/s)$–diagonal words Y. □

Proposition 4.181 (Compliance-to-measurement bounds)**.** *There exist absolute constants $c_1, c_2, c_3 > 0$ (independent of system size and gauge) such that*

$$\mathcal{W}_{\mathrm{vis}} \;\le\; c_1 \, \Delta, \qquad \mathcal{L}_{\mathrm{res}} \;\le\; c_2 \, \Delta, \qquad \max\{\mathcal{A}^{(2)}_{ps}, \mathcal{A}^{(2)}_{sp}\} \;=\; \eta, \qquad \sup_{Y} \; \mathcal{P}_{\mathrm{mis}}(Y) \;\le\; c_3 \, \zeta.$$

Hence the holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ gives a state-independent envelope for interferometric and lensing deviations and diagonal pinching errors. In particular, $\mathfrak{K} = \vec{0}$ if and only if $\mathcal{W}_{\mathrm{vis}} = \mathcal{L}_{\mathrm{res}} = 0$, $\mathcal{A}^{(2)}_{ps} = \mathcal{A}^{(2)}_{sp} = 0$, and $\mathcal{P}_{\mathrm{mis}}(Y) = 0$ for all diagonal Y.

Proof idea. For the first two bounds, write holosymmetric effects in the lensing (commutator) normal form (Definition 3.12) and use the lensing equality in the central case (Corollary 3.22). A centrality defect Δ controls the variation of these effects under control-basis rotations and branch swap, hence the induced visibility and lensing differences; the constants absorb universal factors (e.g. the $1/4$ in the symmetric lensing effect). For the third, η is defined as the operator norm of the two-step edge (Definition 4.172). For the fourth, almost-commutation $\zeta = \|[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda]\|$ controls the deviation from the pinched diagonal via the *pinching-stability* Lemma Lemma 4.180; in the exact commuting case ($\zeta = 0$), the pinching coincides with the conditional expectation described in Remark Remark 4.182. Gauge covariance preserves all relevant norms throughout (Proposition 4.54 and Corollary 4.64).

Proof. **Preliminaries.** We work with: (a) the symmetric interferometer and its probabilities (Definition 2.123 and eq. (3.1)); (b) the commutator ("lensing") normal form (Definition 3.12); (c) the control–block split $\mathbf{U}_{\mathrm{ctrl}} = I_c \otimes U_+ + Z_c \otimes U_-$ (eq. (3.46)), which yields $[R, \mathbf{U}_{\mathrm{ctrl}}] = [R, Z_c] \otimes U_-$ for any control rotation $R \in \mathrm{SU}(2)$; (d) gauge covariance and norm preservation of channels (Proposition 4.54 and Corollary 4.64); and (e) the operational diagnostics $\mathcal{W}_{\mathrm{vis}}, \mathcal{L}_{\mathrm{res}}, \mathcal{A}^{(2)}_{ps}, \mathcal{A}^{(2)}_{sp}, \mathcal{P}_{\mathrm{mis}}$ (Definition 4.179), together with the defects Δ (centrality, Definition 4.112), η (nilpotency, Definition 4.172), ζ (bosonic-commutation, Definition 4.175).

(i) $\mathcal{W}_{\mathrm{vis}} \le c_1\,\Delta$. In the symmetric Mach–Zehnder realization (Definition 2.123), the control outcomes are governed by holosymmetric effects that decompose into "sum" and "difference" histories with universal $1/4$ prefactors (cf. eq. (3.1) and the derivation via Definition 3.12). Varying the control basis R modifies the effects by commutators where the only nontrivial, defect-sensitive contribution arises from failures of the ss block to commute with the word implementing the basis change. By the definition of centrality defect $\Delta = \sup \|[\hat{G}^{ss}_\Lambda, \cdot]\|$ (Definition 4.112) and submultiplicativity, the variation of the effects — and hence the visibility envelope $\mathcal{W}_{\mathrm{vis}}$ (Definition 4.179) — is bounded by a universal constant times Δ. All gauge choices are immaterial by Proposition 4.54 and Corollary 4.64. Thus $\mathcal{W}_{\mathrm{vis}} \le c_1\,\Delta$.

(ii) $\mathcal{L}_{\mathrm{res}} \le c_2\,\Delta$. *Lensing equality* states that the symmetric and asymmetric lensing effects coincide when the ss block is central (Definition 3.12 together with the equality statement in Corollary 3.22). With a nonzero centrality defect, their difference decomposes into a finite sum of graded commutators, each bounded by Δ up to the same universal constants (inherited from the interferometer's $1/4$ factors). Taking suprema over lensing settings (as in Definition 4.179) gives $\mathcal{L}_{\mathrm{res}} \le c_2\,\Delta$. Gauge invariance follows as in (i).

(iii) $\max\{\mathcal{A}^{(2)}_{ps}, \mathcal{A}^{(2)}_{sp}\} = \eta$. By definition (Definitions 4.172 and 4.179),

$$\eta = \max\Big\{ \|(\hat{G}^{ps}_\Lambda)^2\|,\ \|(\hat{G}^{sp}_\Lambda)^2\| \Big\} = \max\{\mathcal{A}^{(2)}_{ps}, \mathcal{A}^{(2)}_{sp}\}.$$

Under exact word-level nilpotency (Theorem 4.170) both norms vanish.

(iv) $\sup_Y \mathcal{P}_{\mathrm{mis}}(Y) \le c_3\,\zeta$. Let Π be the $(0/s)$–diagonal pinching used in Definition 4.179. By Lemma 4.180 we have $\|Y - \Pi(Y)\| \le C\,\zeta$ for a universal C and all $(0/s)$–diagonal words Y; hence $c_3 := C$ works.

Conclusion. Items (i)–(iv) yield the stated bounds. Moreover, the diagnostics vanish precisely when their controlling defects vanish: (iii) is tautological; (i)–(ii) reduce to exact centrality

($\Delta = 0$) via Corollary 3.22; (iv) reduces to exact commutation ($\zeta = 0$) by Lemma 4.180. Therefore

$$\mathfrak{K} = \vec{0} \iff \mathcal{W}_{\mathrm{vis}} = \mathcal{L}_{\mathrm{res}} = 0, \quad \mathcal{A}^{(2)}_{ps} = \mathcal{A}^{(2)}_{sp} = 0, \quad \mathcal{P}_{\mathrm{mis}}(Y) = 0 \ \ \forall Y,$$

and the proposition follows. □

Remark 4.182 (Spectral pinching as conditional expectation when $\zeta = 0$)**.** Assume the bosonic $0/s$ compatibility $[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda] = 0$ (Theorem 4.173) and let $\mathcal{D}_{0s}$ be the von Neumann subalgebra generated by the joint spectral projections of the commuting pair $(\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda)$ inside the $(0/s)$-diagonal block (Definition 4.81). Then the pinching map Π used in Definition 4.179 coincides with the normal conditional expectation $\mathsf{E}_{0s} : \mathcal{B}(\mathcal{H}^{(2n)}_{\mathrm{RR}}) \to \mathcal{D}_{0s}$ given by the joint-spectral pinching

$$\mathsf{E}_{0s}(Y) \ = \ \int_\sigma E(d\omega)\, Y\, E(d\omega),$$

where E is the joint spectral measure of $(\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda)$ and σ its joint spectrum. In particular, $\Pi = \mathsf{E}_{0s}$ is normal, unital, completely positive, contractive with $\|\Pi\| = 1$, idempotent $\Pi^2 = \Pi$, and $\mathcal{D}_{0s}$-bimodular: $\Pi(D_1 Y D_2) = D_1\, \Pi(Y)\, D_2$ for all $D_1, D_2 \in \mathcal{D}_{0s}$. Hence $\mathrm{Fix}(\Pi) = \mathcal{D}_{0s}$ and, for any $(0/s)$-diagonal word Y, $\|Y - \Pi(Y)\| = 0$. For $\zeta > 0$ (almost-commutation), Lemma 4.180 gives the quantitative stability bound $\|Y - \Pi(Y)\| \le C\,\zeta$, uniform under endpoint gauge by Proposition 4.54 and Corollary 4.64.

Definition 4.183 (Compliance regimes)**.** Fix thresholds $\varepsilon_\Delta, \varepsilon_\eta, \varepsilon_\zeta > 0$. The *holosymmetric ε-compliant regime* is

$$\mathcal{R}_\varepsilon \ := \ \Big\{ \ \mathfrak{K} \in \mathbb{R}^3_{\ge 0} : \ \Delta \le \varepsilon_\Delta, \ \eta \le \varepsilon_\eta, \ \zeta \le \varepsilon_\zeta \ \Big\}.$$

By Proposition 4.181, $\mathcal{R}_\varepsilon$ induces uniform bounds on $\mathcal{W}_{\mathrm{vis}}, \mathcal{L}_{\mathrm{res}}, \mathcal{A}^{(2)}_{ps}, \mathcal{A}^{(2)}_{sp}, \mathcal{P}_{\mathrm{mis}}$.

Definition 4.184 (Extended holosymmetric compliance profile)**.** Let $\mathcal{J}$ be a finite index set of defect functionals $\{\delta_j\}_{j\in\mathcal{J}}$, each $\delta_j \ge 0$, gauge-invariant under endpoint conjugation, and operationally measurable (cf. Definition 4.179). Define the *compliance profile*

$$\mathfrak{K}_{\mathcal{J}} \ := \ (\delta_j)_{j\in\mathcal{J}} \ \in \ \mathbb{R}^{|\mathcal{J}|}_{\ge 0}.$$

As a default baseline, take $\mathcal{J}_0 = \{\Delta, \eta, \zeta\}$, recovering $\mathfrak{K}_{\mathcal{J}_0} = (\Delta, \eta, \zeta)$ in $\mathbb{R}^3_{\ge 0}$.

Definition 4.185 (General compliance regimes)**.** Given thresholds $\varepsilon = (\varepsilon_j)_{j\in\mathcal{J}} \in \mathbb{R}^{|\mathcal{J}|}_{>0}$, the *$\varepsilon$-compliant regime* is

$$\mathcal{R}^{\mathcal{J}}_\varepsilon \ := \ \Big\{ \mathfrak{K}_{\mathcal{J}} \in \mathbb{R}^{|\mathcal{J}|}_{\ge 0} \ : \ \delta_j \le \varepsilon_j \ \ \forall\, j \in \mathcal{J} \Big\}.$$

For the baseline $\mathcal{J}_0 = \{\Delta, \eta, \zeta\}$, this reduces to $\mathcal{R}^{\mathcal{J}_0}_\varepsilon = \{(\Delta, \eta, \zeta) : \Delta \le \varepsilon_\Delta, \ \eta \le \varepsilon_\eta, \ \zeta \le \varepsilon_\zeta\} \subset \mathbb{R}^3_{\ge 0}$.

Remark 4.186 (Comparing profiles and choosing dimensions)**.** (i) **Projection/dominance.** Any extended profile projects onto the baseline via $\pi_{\mathcal{J}_0}(\mathfrak{K}_{\mathcal{J}}) = (\Delta, \eta, \zeta)$; membership in $\mathcal{R}_\varepsilon^{\mathcal{J}}$ implies membership in $\mathcal{R}_\varepsilon^{\mathcal{J}_0}$, but not conversely.

(ii) **Aggregates.** For a single-number certificate, use a weighted max or norm, e.g. $\|\mathfrak{K}_{\mathcal{J}}\|_{\infty,w} := \max_{j\in\mathcal{J}} w_j\, \delta_j$.

(iii) **Suggested extensions.** Beyond $\{\Delta, \eta, \zeta\}$, typical δ_j include: orthogonality defect of the triadic decomposition (Proposition 4.475); flatness/leakage along transports (via curvature bounds); endpoint-covariance drift; typing leakage; normal-form residual for ss; and spectral pinching/tomography residuals (cf. Definition 4.179).

Proposition 4.187 (Diagonal $0/s$ refinement of triadic metric/time)**.** *Assume bosonic $0/s$ compatibility (Theorem 4.173) so that $[\,\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda\,] = 0$. Then at each locus x there exists a joint spectral resolution for the endpoint projectors $P_0(x), P_s(x)$ and the diagonal channel observables built from them. Consequently, the diagonal part of the triadic fibres (Sections 4.10 and 4.12) splits as a direct sum*

$$\mathcal{F}^{\mathrm{dist}}_{x,\mathrm{diag}} \;\cong\; \mathcal{F}^{\mathrm{dist},(0)}_x \oplus \mathcal{F}^{\mathrm{dist},(s)}_x, \qquad \mathcal{F}^{\mathrm{time}}_{x,\mathrm{diag}} \;\cong\; \mathcal{F}^{\mathrm{time},(0)}_x \oplus \mathcal{F}^{\mathrm{time},(s)}_x,$$

and one can define refined diagonal contributions

$$d^{(0)}_{\mathrm{vac}}(x,x'),\; d^{(s)}_{\mathrm{vac}}(x,x'), \qquad t^{(0)}_{\mathrm{vac}}(x,x'),\; t^{(s)}_{\mathrm{vac}}(x,x'),$$

whose sum recovers the diagonal components in the triadic metric/time (Definition 4.463 and eqs. (4.210) and (4.211)). These refinements are gauge-invariant and orthogonal to the off-diagonal correlator/spectral axes by Proposition 4.475.

Proof idea. Commutation yields simultaneous functional calculus for diagonal words, so one can project the diagonal contribution onto 0 and s sectors at both endpoints. Orthogonality with correlator/spectral parts follows from Proposition 4.475, and gauge covariance from Proposition 4.54 and Corollary 4.64.

Proof. Preliminaries. Work over the base $\mathcal{C}_d$ of Definition 4.617. All fibrewise objects live in the Hilbert bundle $\pi : \mathfrak{F} \to \mathcal{C}_d$ ((4.302)) with spectral restriction ((4.303)). Transport and gauge covariance are those of Section 4.19.1.

Step 1: Diagonal observables and block support. Fix endpoints (x, x'). Let

$$P_\alpha(x) := \hat{\mathcal{F}}^\dagger_\alpha(x)\hat{\mathcal{F}}_\alpha(x), \qquad P_\alpha(x') := \hat{\mathcal{F}}^\dagger_\alpha(x')\hat{\mathcal{F}}_\alpha(x') \quad (\alpha \in \{0, s\}).$$

By typing/orthogonality of endpoint selectors (Remark 4.140), $P_0(x)P_s(x) = P_s(x)P_0(x) = 0$ and similarly at x'. Define the (endpoint) diagonal channel observables at x

$$\mathsf{O}_{00}(x) := \hat{G}^{00}_\Lambda(x,x')\,\hat{G}^{00}_\Lambda(x,x')^\dagger, \qquad \mathsf{O}_{ss}(x) := \hat{G}^{ss}_\Lambda(x,x')\,\hat{G}^{ss}_\Lambda(x,x')^\dagger,$$

and analogously at x' with adjoint order reversed. Because $\hat{G}^{00}_\Lambda(x,x') = P_0(x)\hat{G}^{00}_\Lambda(x,x')P_0(x')$ and $\hat{G}^{ss}_\Lambda(x,x') = P_s(x)\hat{G}^{ss}_\Lambda(x,x')P_s(x')$ by typing, we have the support relations

$$\mathsf{O}_{00}(x) = P_0(x)\,\mathsf{O}_{00}(x)\,P_0(x), \qquad \mathsf{O}_{ss}(x) = P_s(x)\,\mathsf{O}_{ss}(x)\,P_s(x),$$

hence $\mathsf{O}_{00}(x)\mathsf{O}_{ss}(x) = \mathsf{O}_{ss}(x)\mathsf{O}_{00}(x) = 0$.

Step 2: Joint spectral resolution on the diagonal family. By bosonic compatibility, $[\hat{G}^{00}_\Lambda, \hat{G}^{ss}_\Lambda] = 0$ (Theorem 4.173). Therefore the normal operators $\mathsf{O}_{00}(x)$ and $\mathsf{O}_{ss}(x)$ commute. They also commute with $P_0(x), P_s(x)$ because each is supported on its own range. Thus the family $\{P_0(x), P_s(x), \mathsf{O}_{00}(x), \mathsf{O}_{ss}(x)\}$ is a commuting set of normal operators on the modal fibre at x. By the joint spectral theorem, there exists a joint spectral measure resolving them simultaneously. The same holds at x'.

Step 3: Algebraic splitting of the diagonal subalgebra. Let $\mathsf{A}_{x,\mathrm{diag}}$ be the unital C^*-algebra generated by $\{P_0(x), P_s(x), \mathsf{O}_{00}(x), \mathsf{O}_{ss}(x)\}$. Because $P_0(x), P_s(x)$ are orthogonal central idempotents in $\mathsf{A}_{x,\mathrm{diag}}$, the map

$$\Phi : \mathsf{A}_{x,\mathrm{diag}} \longrightarrow P_0(x)\mathsf{A}_{x,\mathrm{diag}}P_0(x) \oplus P_s(x)\mathsf{A}_{x,\mathrm{diag}}P_s(x), \quad A \mapsto \Big(P_0(x)AP_0(x),\ P_s(x)AP_s(x)\Big)$$

is a C^*-isomorphism (standard block decomposition by orthogonal central projections). Define

$$\mathsf{A}^{(0)}_x := P_0(x)\mathsf{A}_{x,\mathrm{diag}}P_0(x), \qquad \mathsf{A}^{(s)}_x := P_s(x)\mathsf{A}_{x,\mathrm{diag}}P_s(x).$$

Then $\mathsf{A}_{x,\mathrm{diag}} \cong \mathsf{A}^{(0)}_x \oplus \mathsf{A}^{(s)}_x$.

Step 4: Splitting of diagonal triadic fibres. By definition of the triadic fibres (Sections 4.10 and 4.12), $\mathcal{F}^{\mathrm{dist}}_{x,\mathrm{diag}}$ (resp. $\mathcal{F}^{\mathrm{time}}_{x,\mathrm{diag}}$) is the closure of diagonal observables/functions contributing to the diagonal part of the distance (resp. time) functionals, with the Holo-State pairing $\langle\!\langle \cdot, \cdot \rangle\!\rangle_\Psi$. Restricting the pairing to the two blocks and using $P_0(x)P_s(x) = 0$ one checks

$$\langle\!\langle A_0,\ A_s \rangle\!\rangle_\Psi \ = \ 0 \quad \text{for all } A_0 \in \mathsf{A}^{(0)}_x,\ A_s \in \mathsf{A}^{(s)}_x,$$

because each mixed product factors through $P_0(x)P_s(x)$ or $P_s(x)P_0(x)$ and vanishes by typing. Hence the diagonal fibre decomposes orthogonally as

$$\mathcal{F}^{\mathrm{dist}}_{x,\mathrm{diag}} \ \cong \ \mathcal{F}^{\mathrm{dist},(0)}_x \ \oplus \ \mathcal{F}^{\mathrm{dist},(s)}_x, \qquad \mathcal{F}^{\mathrm{time}}_{x,\mathrm{diag}} \ \cong \ \mathcal{F}^{\mathrm{time},(0)}_x \ \oplus \ \mathcal{F}^{\mathrm{time},(s)}_x,$$

where $\mathcal{F}^{\mathrm{dist},(\alpha)}_x$ and $\mathcal{F}^{\mathrm{time},(\alpha)}_x$ are the closures of $P_\alpha(x)\mathsf{A}_{x,\mathrm{diag}}P_\alpha(x)$ under the respective pairings ($\alpha \in \{0, s\}$).

Step 5: Refined diagonal contributions and reconstruction. Let Π_α be the block pinching onto the α-sector at x and x' (cf. the pinching map in Theorem 4.173, case (B3$^{\mathrm{word}}$)). Define the refined diagonal distances by applying the original diagonal functional (Definition 4.463 and eqs. (4.210) and (4.211)) to the pinched observables:

$$d^{(\alpha)}_{\mathrm{vac}}(x, x') := d_{\mathrm{vac}}\Big(\Pi_\alpha[\text{diag data at } (x, x')]\Big), \qquad \alpha \in \{0, s\}.$$

Likewise define $t^{(\alpha)}_{\mathrm{vac}}(x, x')$ from the diagonal time functional. Because the two sectors are orthogonal in the Holo-State pairing (above), the total diagonal contributions satisfy the Pythagorean additivity

$$d_{\mathrm{vac}}(x, x')^2 \ = \ \Big(d^{(0)}_{\mathrm{vac}}(x, x')\Big)^2 + \Big(d^{(s)}_{\mathrm{vac}}(x, x')\Big)^2, \qquad t_{\mathrm{vac}}(x, x')^2 \ = \ \Big(t^{(0)}_{\mathrm{vac}}(x, x')\Big)^2 + \Big(t^{(s)}_{\mathrm{vac}}(x, x')\Big)^2,$$

so their square-root sums recover the diagonal components of the triadic metric/time.

Step 6: Orthogonality to off-diagonal axes and gauge invariance. By Proposition 4.475, diagonal contributions are orthogonal (in the Holo-State pairing) to the correlator-based and spectral-shear parts; the refinement above keeps us inside the diagonal subspace, hence preserves this orthogonality. Under endpoint conjugation $X \mapsto g(x)\, X\, g(x')^\dagger$ (Proposition 4.54 and Corollary 4.64), the families $\{P_\alpha(x)\}$ and $\{\mathsf{O}_{\alpha\alpha}(x)\}$ transform by unitary conjugation; joint spectra and the induced quadratic functionals are invariant. Therefore the refined quantities and the direct-sum splittings are gauge-invariant.

Conclusion. We have (i) a joint spectral resolution for the commuting diagonal family, (ii) an orthogonal direct-sum decomposition of diagonal triadic fibres into 0 and s sectors, and (iii) refined diagonal distance/time components whose (Pythagorean) sums reconstruct the original diagonal parts, all gauge-invariant and orthogonal to the off-diagonal axes. □

Proposition 4.188 (ss-normal form for channel words)**.** *If central holosymmetry holds (Theorem 4.169), then every word $W \in \mathsf{G}$ admits a normal form*

$$W \;\sim\; \big(\hat{G}^{ss}_\Lambda\big)^m \;\cdot\; W_{\mathrm{red}} \quad \textit{with} \quad [\,\hat{G}^{ss}_\Lambda,\; W_{\mathrm{red}}\,] = 0,$$

where $m \geq 0$ and W_{red} contains no internal ss-letters. The factorization is unique up to endpoint gauge (Proposition 4.54) and commuting diagonal words.

Proof idea. Since $\hat{G}^{ss}_\Lambda$ commutes with all letters, slide each ss factor to one side using block composition (Proposition 4.85). Gauge conjugations preserve commutators and zero blocks, giving uniqueness modulo endpoint dressing.

Proof. Preliminaries. Work over the base $\mathcal{C}_d$ of Definition 4.617; words are evaluated on fibres of $\mathfrak{F}$ with (4.303) and transported by Section 4.19.1.

Setup and notation. Let

$$W = \hat{G}^{\alpha_n\alpha_{n-1}}_\Lambda(x_n, x_{n-1}) \cdots \hat{G}^{\alpha_1\alpha_0}_\Lambda(x_1, x_0)$$

be a typed channel word (Definition 4.141). Write $S(W) := \{j \in \{1, \dots, n\} : \alpha_j = \alpha_{j-1} = s\}$ for the set of ss-letters in W, and set $m := |S(W)|$.

Step 1: Existence by induction on m. We show that for every m there is a factorization

$$W = \Big(\prod_{j \in S(W)} \hat{G}^{ss}_\Lambda(x_j, x_{j-1}) \Big) \cdot W_{\mathrm{red}},$$

where W_{red} is a word with no ss-letters. Because $\hat{G}^{ss}_\Lambda$ is central (Theorem 4.169), the product of the ss-letters commutes with every factor; hence the order of the ss-letters in the left product is immaterial.

Base case $m = 0$. Then $S(W) = \varnothing$ and the claim holds with $W_{\mathrm{red}} = W$.

Inductive step. Assume the statement for all words with fewer than $m \geq 1$ ss-letters. Choose the leftmost ss-letter at position j, and decompose

$$W = A \cdot \hat{G}^{ss}_\Lambda(x_j, x_{j-1}) \cdot B,$$

with $A := \hat{G}^{\alpha_n\alpha_{n-1}} \cdots \hat{G}^{\alpha_{j+1}\alpha_j}$ and $B := \hat{G}^{\alpha_{j-1}\alpha_{j-2}} \cdots \hat{G}^{\alpha_1\alpha_0}$ (both possibly empty). By centrality, $[\,\hat{G}^{ss}_\Lambda, \cdot\,] = 0$ on G (Theorem 4.169), so

$$W = \hat{G}^{ss}_\Lambda(x_j, x_{j-1}) \cdot (A\,B).$$

By block composition through the intermediate locus x_j (Propositions 4.85 and 4.143 (iii)), the concatenation $A\,B$ is again a well-typed word with endpoints (x_n, x_0). Moreover $A\,B$ has exactly $m-1$ ss-letters. Apply the induction hypothesis to $A\,B$ to obtain

$$A\,B = \Big(\prod_{k \in S(A\,B)} \hat{G}^{ss}_\Lambda(\cdots) \Big) \cdot W_{\mathrm{red}}.$$

Combining the two displays gives the desired factorization for W, with the total left factor being the (commuting) product over all $j \in S(W)$, and W_{red} containing no ss-letters.

Step 2: Commutation with W_{red}. Since $\hat{G}^{ss}_\Lambda$ is central in G (Theorem 4.169), it commutes with every word, in particular with W_{red}. Thus $[\,\hat{G}^{ss}_\Lambda, W_{\mathrm{red}}\,] = 0$.

Step 3: Compressing the left factor to $\big(\hat{G}^{ss}_\Lambda\big)^m$. The left factor is a product of m ss-letters (with possibly different intermediate loci and paths), all commuting with each other and with W_{red}. We denote any such commuting m-fold product by $\big(\hat{G}^{ss}_\Lambda\big)^m$; because these elements lie in the (commutative) diagonal subalgebra generated by $0/s$-diagonals (Theorem 4.173, case ($\mathrm{B3}^{\mathrm{word}}$)), this notation is unambiguous up to multiplication by commuting diagonal words obtained from path/block recombinations (Proposition 4.85).

Step 4: Gauge covariance. Under endpoint gauge $X \mapsto g(x_n) X g(x_0)^\dagger$ (Proposition 4.54 and Corollary 4.64), both $\big(\hat{G}^{ss}_\Lambda\big)^m$ and W_{red} transform by conjugation. Hence the existence of the normal form and the commutation relation are gauge-invariant statements.

Step 5: Uniqueness up to endpoint gauge and commuting diagonal words. Suppose we have two normal forms

$$W = \big(\hat{G}^{ss}_\Lambda\big)^m W_{\mathrm{red}} = \big(\hat{G}^{ss}_\Lambda\big)^{m'} W'_{\mathrm{red}},$$

with $W_{\mathrm{red}}, W'_{\mathrm{red}}$ containing no ss-letters. Moving the central factors to the same side and cancelling yields

$$W_{\mathrm{red}} \;=\; D \;\cdot\; W'_{\mathrm{red}}, \qquad D := \big(\hat{G}^{ss}_\Lambda\big)^{m'-m}.$$

By construction, D belongs to the (commutative) diagonal $0/s$ subalgebra (Theorem 4.173, case ($\mathrm{B3}^{\mathrm{word}}$)) and commutes with both W_{red} and W'_{red}. Moreover, any further ambiguity from regrouping paths/blocks amounts to inserting endpoint conjugations (gauge) and multiplying by diagonal words (again commuting) (Propositions 4.54 and 4.85). Therefore the normal form is unique up to endpoint gauge and commuting diagonal words.

Conclusion. Every word admits the stated factorization with commuting $\hat{G}^{ss}_\Lambda$-power on the left and an ss-free remainder, unique modulo endpoint gauge and diagonal commuting factors. □

Definition 4.189 (p/s-cohomology and invariants)**.** Let $\mathcal{H}_p, \mathcal{H}_s$ be the p- and s-typed modal fibres at a locus. Define the two-term complex

$$0 \longrightarrow \mathcal{H}_p \xrightarrow{d_{ps} := \hat{G}^{ps}_\Lambda} \mathcal{H}_s \longrightarrow 0.$$

Under exact nilpotency (Theorem 4.170), $d_{ps}^2 = 0$ and the cohomology groups

$$H_{ps}^0 \;:=\; \ker(d_{ps}), \qquad H_{ps}^1 \;:=\; \mathcal{H}_s/\mathrm{im}(d_{ps})$$

are well-defined, gauge-invariant under endpoint conjugation, and stable under block composition. Their dimensions and induced pairings are *robust invariants* of synthesis–holothesis coupling.

Proposition 4.190 (Stability under small nilpotency defect)**.** *With nilpotency defect η (Definition 4.172), let $d_{ps} = \hat{G}_\Lambda^{ps} : \mathcal{H}_p \to \mathcal{H}_s$ and fix a tolerance $\tau > \sqrt{\eta}$. Define τ-pseudokernels/images by*

$$\ker_\tau(d_{ps}) = \{v \in \mathcal{H}_p :\ \|d_{ps}v\| \le \tau\|v\|\}, \quad \mathrm{im}_\tau(d_{ps}) = \{d_{ps}u + \delta :\ \|\delta\| \le \tau\|u\|\}.$$

Then the quotient $\widetilde{H}_{ps}^1(\tau) := \mathcal{H}_s/\mathrm{im}_\tau(d_{ps})$ and $\ker_\tau(d_{ps})$ are well-defined and their dimensions are constant for all $\tau \in (\sqrt{\eta}, \tau_0]$. In particular, the exact cohomology is recovered as $\eta \to 0$.

Proof. Preliminaries. Work in finite-dimensional Hilbert spaces $\mathcal{H}_p, \mathcal{H}_s$ (relevant fibres of the words calculus). Take the singular value decomposition (SVD) $d_{ps} = U\Sigma V^\dagger$ with singular values $s_1 \ge \cdots \ge s_r > 0$ and the rest zero. Let $\{v_i\} \subset \mathcal{H}_p$ (right singular vectors) and $\{u_i\} \subset \mathcal{H}_s$ (left singular vectors) be orthonormal bases with $d_{ps}v_i = s_i u_i$ for $1 \le i \le r$, and $d_{ps}v_i = 0$ for $i > r$.

1) Structure of the τ-pseudokernel. Write any $v = \sum_i a_i v_i$. Then $\|d_{ps}v\|^2 = \sum_i s_i^2|a_i|^2$ and $\|v\|^2 = \sum_i |a_i|^2$. Thus $v \in \ker_\tau(d_{ps})$ iff $\sum_i (s_i^2 - \tau^2)|a_i|^2 \le 0$. Because each term is ≥ 0 when $s_i > \tau$ and ≤ 0 when $s_i \le \tau$, this inequality forces $a_i = 0$ for all i with $s_i > \tau$. Conversely, any linear combination of v_i with $s_i \le \tau$ satisfies the inequality. Hence

$$\ker_\tau(d_{ps}) \;=\; \mathrm{span}\{\, v_i :\ s_i \le \tau \,\},$$

and $\dim \ker_\tau(d_{ps})$ equals the counting function $N_\le(\tau) := \#\{i :\ s_i \le \tau\}$. This dimension is constant for τ in any interval avoiding singular values.

2) Structure of the τ-pseudoimage (with the current definition). Given $y \in \mathcal{H}_s$, expand $y = \sum_i b_i u_i$. We need $y = d_{ps}u + \delta$ with $\|\delta\| \le \tau\|u\|$. Let $u = \sum_i a_i v_i$. Then $d_{ps}u = \sum_i s_i a_i u_i$ and $\delta = \sum_i (b_i - s_i a_i)u_i$. The constraint reads $\sum_i |b_i - s_i a_i|^2 \le \tau^2 \sum_i |a_i|^2$. This decouples coordinatewise and is satisfiable for *every* choice of $\{b_i\}$: for each i, pick

$$a_i \;=\; \frac{b_i}{s_i + \tau} \quad (s_i + \tau > 0),$$

which gives $|b_i - s_i a_i| = \frac{\tau}{s_i+\tau}|b_i| \le \tau|a_i|$. Summing over i yields the required inequality. Therefore

$$\mathrm{im}_\tau(d_{ps}) \;=\; \mathcal{H}_s \qquad \text{for every } \tau > 0.$$

Consequently, $\widetilde{H}_{ps}^1(\tau) = \mathcal{H}_s/\mathrm{im}_\tau(d_{ps}) = \{0\}$ and $\dim \widetilde{H}_{ps}^1(\tau) = 0$, a constant.

3) Constancy on $(\sqrt{\eta}, \tau_0]$. Because $\dim \ker_\tau(d_{ps})$ is the counting function $N_\le(\tau)$ of singular values, it is piecewise constant and can change only when τ crosses a singular value. Pick $\tau_0 > \sqrt{\eta}$ that does not coincide with any singular value and (if desired) lies below the next

larger singular value; then $\dim \ker_\tau(d_{ps})$ is constant for all $\tau \in (\sqrt{\eta}, \tau_0]$. The dimension of $\widetilde{H}^1_{ps}(\tau)$ is 0 for all $\tau > 0$, hence constant on that interval.

4) Gauge covariance and recovery in the exact limit. Under endpoint conjugations (gauge) $d_{ps} \mapsto g_s\, d_{ps}\, g_p^\dagger$ (Proposition 4.54 and Corollary 4.64), singular values are unchanged, so both constructions are gauge-invariant.

In the exact nilpotent case ($\eta = 0,\ d_{ps}^2 = 0$), we can take $\tau \downarrow 0$: then $\ker_\tau(d_{ps}) \downarrow \ker(d_{ps})$, and $\mathrm{im}_\tau(d_{ps})$ (as defined here) remains $\mathcal{H}_s$, so $\widetilde{H}^1_{ps}(\tau)$ collapses to 0. (See the remark below for a refinement that yields a nontrivial, stable H^1.) □

Remark 4.191 (Why the absolute pseudoimage is too permissive)**.** With the absolute-residual definition

$$\mathrm{im}_\tau(d) \;:=\; \Big\{\, du + \delta \;:\; \|\delta\| \le \tau\, \|u\| \Big\},$$

one always has $\mathrm{im}_\tau(d) = \mathcal{H}_s$ for every $\tau > 0$. Intuitively, the tolerance scales with $\|u\|$, so one can absorb any desired residual δ by rescaling u; more precisely, an SVD calculation shows every $y \in \mathcal{H}_s$ admits a decomposition $y = du + \delta$ with $\|\delta\| \le \tau\|u\|$. Consequently the quotient $\mathcal{H}_s/\mathrm{im}_\tau(d)$ is always trivial.

A nontrivial and stable alternative is to measure the residual *relative to the output*, and define the *relative pseudoimage*

$$\mathrm{im}^{\mathrm{rel}}_\tau(d) \;:=\; \Big\{\, du + \delta \;:\; \|\delta\| \le \tau\, \|du\| \Big\}.$$

Equivalently (and more spectrally transparent),

$$\mathrm{im}^{\mathrm{spec}}_\tau(d) \;:=\; \mathrm{Ran}\, \mathbf{1}_{(\tau,\infty)}\Big(\sqrt{dd^\dagger}\Big),$$

and $\mathrm{im}^{\mathrm{rel}}_\tau(d)$ has the same closure as $\mathrm{im}^{\mathrm{spec}}_\tau(d)$. Let $d = U\Sigma V^\dagger$ be an SVD with singular values (s_i), right singular vectors (v_i), and left singular vectors (u_i). Then (see Lemma 4.193):

$$\ker_\tau(d) = \mathrm{span}\{\, v_i :\ s_i \le \tau \,\}, \qquad \overline{\mathrm{im}^{\mathrm{rel}}_\tau(d)} = \overline{\mathrm{im}^{\mathrm{spec}}_\tau(d)} = \mathrm{span}\{\, u_i :\ s_i > \tau \,\},$$

so that

$$\dim \ker_\tau(d) = \Big|\{\, i :\ s_i \le \tau \,\}\Big|, \qquad \dim\Big(\mathcal{H}_s \Big/ \overline{\mathrm{im}^{\mathrm{rel}}_\tau(d)}\Big) = \Big|\{\, i :\ s_i \le \tau \,\}\Big|.$$

Both dimensions are constant for τ varying in any interval that avoids singular values. In the exact limit, taking $\tau \downarrow 0$ (with $\tau > \sqrt{\eta}$ and $\eta \to 0$) recovers the usual cohomology: $\ker(d)$ and $\mathcal{H}_s/\mathrm{im}(d)$. Here $|\cdot|$ denotes cardinality (possibly $+\infty$).

Definition 4.192 (Spectral pseudoimage and pseudokernel)**.** Let $d_{ps} = \hat{G}^{ps}_\Lambda : \mathcal{H}_p \to \mathcal{H}_s$ and let $\sqrt{d_{ps} d_{ps}^\dagger}$ have singular values $(s_i)_{i=1}^r > 0$ (the rest $= 0$). For $\tau \ge 0$ define

$$\ker_\tau(d_{ps}) := \{v \in \mathcal{H}_p :\ \|d_{ps} v\| \le \tau\, \|v\|\}, \qquad \mathrm{im}^{\mathrm{spec}}_\tau(d_{ps}) := \mathrm{Ran}\, \mathbf{1}_{(\tau,\infty)}\Big(\sqrt{d_{ps} d_{ps}^\dagger}\Big).$$

Lemma 4.193 (SVD characterization)**.** *Let $d_{ps} = U\Sigma V^\dagger$ be an SVD with right singular vectors $\{v_i\} \subset \mathcal{H}_p$ and left singular vectors $\{u_i\} \subset \mathcal{H}_s$, so that $d_{ps} v_i = s_i u_i$, $d_{ps}^\dagger u_i = s_i v_i$ and $s_1 \ge \cdots \ge s_r > 0$. Then for every $\tau \ge 0$,*

$$\ker_\tau(d_{ps}) = \mathrm{span}\{\, v_i :\ s_i \le \tau \,\}, \qquad \mathrm{im}^{\mathrm{spec}}_\tau(d_{ps}) = \mathrm{span}\{\, u_i :\ s_i > \tau \,\}.$$

Proof. Write $v = \sum_i a_i v_i$ with $\|v\|^2 = \sum_i |a_i|^2$ and $\|d_{ps}v\|^2 = \sum_i s_i^2 |a_i|^2$. Then $\|d_{ps}v\| \le \tau\|v\|$ iff $\sum_i (s_i^2 - \tau^2)|a_i|^2 \le 0$, which forces $a_i = 0$ for $s_i > \tau$ and allows arbitrary a_i for $s_i \le \tau$; hence the first identity. The second follows from the spectral projector definition: $\operatorname{Ran} \mathbf{1}_{(\tau,\infty)}(\sqrt{d_{ps}d_{ps}^\dagger}) = \operatorname{span}\{u_i : \ s_i > \tau\}$. □

Proposition 4.194 (Stability of spectral pseudo-cohomology)**.** *Let $d_{ps} = \hat{G}_\Lambda^{ps} : \mathcal{H}_p \to \mathcal{H}_s$ and let $\eta = \|d_{ps}^2\|$ be the nilpotency defect* (Definition 4.172)*. Fix $\tau > 0$ and define*

$$\widetilde{H}_{ps}^1(\tau) \ := \ \mathcal{H}_s \Big/ \operatorname{im}_\tau^{\mathrm{spec}}(d_{ps}).$$

Then:

(a) Piecewise-constant ranks

With $N_\le(\tau) := \#\{i : \ s_i \le \tau\}$ and $N_>(\tau) := \#\{i : \ s_i > \tau\}$,

$$\dim \ker_\tau(d_{ps}) = N_\le(\tau), \qquad \dim \widetilde{H}_{ps}^1(\tau) = N_\le(\tau),$$

and these dimensions are constant for τ varying in any interval that contains no singular value.

(b) Gauge invariance

Under endpoint conjugations $d_{ps} \mapsto g_s \, d_{ps} \, g_p^\dagger$ (Proposition 4.54 and Corollary 4.64)*, the multisets $\{s_i\}$, the subspaces $\ker_\tau(d_{ps})$, $\operatorname{im}_\tau^{\mathrm{spec}}(d_{ps})$, and the quotient $\widetilde{H}_{ps}^1(\tau)$ are unchanged up to unitary equivalence.*

(c) Exact limit

If $\eta = 0$ (exact nilpotency), then as $\tau \downarrow 0$,

$$\ker_\tau(d_{ps}) \ \downarrow \ \ker(d_{ps}), \qquad \operatorname{im}_\tau^{\mathrm{spec}}(d_{ps}) \ \uparrow \ \operatorname{im}(d_{ps}),$$

and thus $\dim \widetilde{H}_{ps}^1(\tau) \to \dim \big(\mathcal{H}_s / \operatorname{im}(d_{ps})\big)$.

Moreover, if you choose τ in any open interval disjoint from the singular values (e.g. $\tau \in (\sqrt{\eta}, \tau_0]$ with τ_0 not a singular value), the ranks in (a) are constant throughout that interval.

Proof. Preliminaries. Endpoints are in $\mathcal{C}_d$; $d_{ps} = \hat{G}_\Lambda^{ps}$ acts between the spectrally restricted fibres of $\mathfrak{F}$ at those endpoints ((4.303)); transport/gauge per Section 4.19.1.

(a) The identities for the dimensions follow immediately from Lemma 4.193. Piecewise constancy is the observation that $N_\le(\tau)$ and $N_>(\tau)$ can jump only when τ crosses a singular value.

(b) Gauge conjugations are unitary on domain and codomain, so they preserve $d_{ps}d_{ps}^\dagger$, hence the spectrum of $\sqrt{d_{ps}d_{ps}^\dagger}$, the SVD singular values, and the spectral subspaces defined by projectors $\mathbf{1}_{(\tau,\infty)}(\cdot)$ and $\mathbf{1}_{[0,\tau]}(\cdot)$. Therefore the two subspaces and the quotient are invariant up to unitary.

(c) If $\eta = 0$, then $d_{ps}^2 = 0$ and (finite-dimensional) $\operatorname{im}(d_{ps})$ is closed. For $\tau \downarrow 0$, $\mathbf{1}_{(\tau,\infty)}(\sqrt{d_{ps}d_{ps}^\dagger})$ increases strongly to $\mathbf{1}_{(0,\infty)}(\cdot)$, whose range is $\overline{\operatorname{im}(d_{ps})} = \operatorname{im}(d_{ps})$; likewise $\ker_\tau(d_{ps})$ decreases to $\ker(d_{ps})$. The rank limits yield the exact cohomology ranks. □

Remark 4.195 (Why we mention $\tau > \sqrt{\eta}$)**.** The SVD/spectral statements above do *not* require any relation between τ and η; they hold for every $\tau \geq 0$. Mentioning $\tau > \sqrt{\eta}$ ties this threshold to your "almost differential" regime and ensures you can choose a *single* interval (e.g. $(\sqrt{\eta}, \tau_0]$) that avoids singular values in practical scenarios, so the ranks are constant on that operational window.

Remark 4.196 (Intuition for spectral pseudo-cohomology)**.** In the SVD picture of d_{ps} (Lemma 4.193 and Proposition 4.194):

- $\ker_\tau(d_{ps})$ collects *domain directions* mapped with gain $\leq \tau$: the **soft modes**.
- $\mathrm{im}_\tau^{\mathrm{spec}}(d_{ps})$ collects *output directions* with singular value $> \tau$: the **hard image**.
- Both sides count the same number of modes at threshold τ, namely those with $s_i \leq \tau$. Hence
$$\dim \ker_\tau(d_{ps}) = \dim\left(\mathcal{H}_s/\mathrm{im}_\tau^{\mathrm{spec}}(d_{ps})\right),$$
and the pseudo-cohomology rank is *piecewise constant* as τ varies away from singular values (Proposition 4.194(a)).
- As $\tau \downarrow 0$ and $\eta \to 0$ (exact nilpotency), one recovers the usual objects:
$$\ker_\tau(d_{ps}) \downarrow \ker(d_{ps}), \qquad \mathrm{im}_\tau^{\mathrm{spec}}(d_{ps}) \uparrow \mathrm{im}(d_{ps}),$$
so $\widetilde{H}^1_{ps}(\tau) \to \mathcal{H}_s/\mathrm{im}(d_{ps})$ (Proposition 4.194(c), Remark 4.195).

This resolves the "too-permissive" absolute pseudoimage (Remark 4.191) and yields a crisp, gauge-invariant, *spectral* notion of *ps*-pseudo-cohomology; gauge covariance follows from endpoint conjugation invariance (Proposition 4.54 and Corollary 4.64).

Corollary 4.197 (Geometric packaging in the fibre)**.** *The structures of Propositions 4.187 and 4.188 and Definition 4.189 assemble over $\mathcal{C}_d$ into bundle data:*

(i) *a bi-diagonal refinement of the diagonal sub-fibres inside $\mathcal{F}^{\mathrm{dist}}$ and $\mathcal{F}^{\mathrm{time}}$;*

(ii) *an ss-central normal-form sheaf on the channel-word bundle; and*

(iii) *a p/s-cohomology sheaf well-defined in the exact case and upper-semicontinuous under small η.*

Proof. emphPreliminaries. Work over $\mathcal{C}_d$ as in Definition 4.617; use $\pi : \mathfrak{F} \to \mathcal{C}_d$ ((4.302)) with (4.303) and the transporter of Section 4.19.1.

(i) Bi-diagonal refinement of diagonal fibres. For each locus x, Proposition 4.187 yields commuting diagonal families and orthogonal central idempotents $P_0(x), P_s(x)$ on the diagonal fibre together with the direct sums
$$\mathcal{F}^{\mathrm{dist}}_{x,\mathrm{diag}} \cong \mathcal{F}^{\mathrm{dist},(0)}_x \oplus \mathcal{F}^{\mathrm{dist},(s)}_x, \qquad \mathcal{F}^{\mathrm{time}}_{x,\mathrm{diag}} \cong \mathcal{F}^{\mathrm{time},(0)}_x \oplus \mathcal{F}^{\mathrm{time},(s)}_x.$$
On any simply connected flat patch, the spectral projectors $P_\alpha(x)$ vary continuously by parallel transport (Propositions 4.54 and 4.59), hence their ranges form continuous subbundles; on

overlaps these bundles glue by endpoint gauge. This produces the desired bi-diagonal refinement bundles inside $\mathcal{F}^{\mathrm{dist}}$ and $\mathcal{F}^{\mathrm{time}}$, fibrewise orthogonal and gauge-invariant (orthogonality to non-diagonal axes is from Proposition 4.475).

(ii) *ss*-central normal-form sheaf. Let $\mathcal{W} \to \mathcal{C}_d$ be the channel-word bundle (fibre G_x). For an open set $U \subset \mathcal{C}_d$, define the presheaf

$$\mathcal{N}_{ss}(U) := \Big\{ \text{ sections } W \text{ on } U \Big/ \sim \Big\},$$

where $W \sim W'$ iff $W' = (\hat{G}^{ss}_{\Lambda})^m \cdot D \cdot W$ for some locally constant $m \geq 0$ and a commuting diagonal word D on U. By Proposition 4.188, each fibre $W(x)$ admits such a factorization and it is unique up to commuting diagonals and endpoint gauge, so local normal forms agree on overlaps; the usual equalizer condition yields sheaf gluing. Hence $\mathcal{N}_{ss}$ is a sheaf (of sets) encoding the *ss*-central normal form on $\mathcal{W}$.

(iii) p/s-cohomology (exact and upper-semicontinuous). In the exact case ($\eta = 0$), Definition 4.189 defines fibrewise $d_{ps}(x) = \hat{G}^{ps}_{\Lambda}(x)$ with $d_{ps}(x)^2 = 0$, and cohomology groups

$$H^0_{ps}(x) = \ker d_{ps}(x), \qquad H^1_{ps}(x) = \mathcal{H}_s(x)/\mathrm{im}\, d_{ps}(x).$$

On flat patches, spectral projectors of $d_{ps}(x)d_{ps}(x)^\dagger$ vary continuously; thus $\ker d_{ps}$ and $\mathrm{im}\, d_{ps}$ define subbundles and H^1_{ps} forms a quotient bundle. These patch by gauge to a cohomology sheaf on $\mathcal{C}_d$.

For small defect $\eta > 0$, pick $\tau > \sqrt{\eta}$ that avoids singular values uniformly on a cover; define the spectral pseudokernel/image by

$$\ker_\tau(d_{ps}(x)) = \mathrm{span}\{v_i(x) : s_i(x) \leq \tau\}, \quad \mathrm{im}^{\mathrm{spec}}_\tau(d_{ps}(x)) = \mathrm{span}\{u_i(x) : s_i(x) > \tau\},$$

and the pseudo-cohomology $\widetilde{H}^1_{ps}(\tau; x) := \mathcal{H}_s(x)/\mathrm{im}^{\mathrm{spec}}_\tau(d_{ps}(x))$. By Proposition 4.194, the ranks $\dim \ker_\tau$ and $\dim \widetilde{H}^1_{ps}(\tau)$ are piecewise constant and remain constant on any open set where no singular value crosses τ; hence the resulting fields are *upper-semicontinuous* bundles, which glue to a sheaf that limits to the exact cohomology sheaf as $\eta \to 0$.

Conclusion. Items (i)–(iii) produce, respectively, a bi-diagonal refinement of diagonal fibres, an *ss*-normal-form sheaf on channel words, and a (pseudo-)cohomology sheaf that is exact for $\eta = 0$ and upper-semicontinuous for small $\eta > 0$, all natural and gauge-invariant over $\mathcal{C}_d$. □

4.3 The Dialectic Super-Commutator

Definition 4.198 (Dialectic super-commutator)**.** Let the component channels carry the color (degree) $\deg(\hat{G}^{\alpha\beta}) := \deg(\alpha) + \deg(\beta) \in \mathbb{Z}_2 \times \mathbb{Z}_2$ (cf. Section 4.1.7). For any two components $\hat{G}^{\alpha\beta}$ and $\hat{G}^{\gamma\delta}$, define the graded bracket

$$\left[\hat{G}^{\alpha\beta}, \hat{G}^{\gamma\delta}\right]_{\mathrm{gr}} := \hat{G}^{\alpha\beta}\hat{G}^{\gamma\delta} - (-1)^{\langle \deg(\alpha)+\deg(\beta),\, \deg(\gamma)+\deg(\delta)\rangle}\hat{G}^{\gamma\delta}\hat{G}^{\alpha\beta}, \tag{4.71}$$

where $\langle (a_1, a_2), (b_1, b_2)\rangle := a_1 b_1 + a_2 b_2 \pmod 2$.

Remark 4.199 (Algebraic properties and selection rules)**.**

1. **Graded $*$-Lie structure.** The bracket $[\,\cdot\,,\,\cdot\,]_{\mathrm{gr}}$ is graded-skew, satisfies the graded Jacobi identity, and obeys $\big([X,Y]_{\mathrm{gr}}\big)^{\dagger} = -\,(-1)^{\langle \deg X, \deg Y\rangle}[X^{\dagger},Y^{\dagger}]_{\mathrm{gr}}$.
2. **Gauge covariance.** Under $g(x) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, $\hat{G}^{\alpha\beta}(x,x') \mapsto g(x)\hat{G}^{\alpha\beta}(x,x')g(x')^{\dagger}$; the bracket is preserved because degree, product, and adjoint are preserved (cf. Sections 4.1.2 and 4.1.4).
3. **Component-wise selection rule.** Let $c_1 := \deg(\hat{G}^{\alpha\beta})$, $c_2 := \deg(\hat{G}^{\gamma\delta})$. Then

$$\big[\hat{G}^{\alpha\beta},\hat{G}^{\gamma\delta}\big]_{\mathrm{gr}} = \begin{cases} [\hat{G}^{\alpha\beta},\hat{G}^{\gamma\delta}] & \text{if } \langle c_1,c_2\rangle = 0, \\ \{\hat{G}^{\alpha\beta},\hat{G}^{\gamma\delta}\} & \text{if } \langle c_1,c_2\rangle = 1, \end{cases}$$

   so the bracket reduces to an *ordinary commutator* unless the color dot-product is 1, in which case it becomes an *anticommutator*. Typical pairings (using $\deg(0) = (0,0)$, $\deg(1) = (1,0)$, $\deg(s) = (0,1)$, $\deg(p) = (1,1)$):

   - Even with anything $(0,0)\cdot(\cdot) = 0$: ordinary commutator.
   - Same odd color: $(1,0)$ with $(1,0)$ or $(0,1)$ with $(0,1)$: anticommutator.
   - Mixed with p: $(1,1)$ with $(1,0)$ or $(0,1)$: anticommutator.
   - Different odd colors $(1,0)$ with $(0,1)$: ordinary commutator.

Remark 4.200 (Physical postulates and analogies)**.** The grading fixes *which* bracket (commutator or anticommutator) is appropriate; dynamics enter through *postulates* that constrain their values. The analogies to bosons/fermions are algebraic, not ontic.

- **Commuting (bosonic-type) sector.** Symmetry–Holosymmetry self-channels are taken compatible: $[\hat{G}^{00},\hat{G}^{ss}] = 0$ (and, more generally, $[\hat{G}^{00},\cdot]$ is always an ordinary commutator since $\deg \hat{G}^{00} = (0,0)$).
- **Anticommuting (fermionic-type) mixing.** Choose a pair with color dot-product = 1; e.g.

$$\{\hat{G}^{10},\hat{G}^{p0}\} = 0,$$

  since $\deg(\hat{G}^{10}) = (1,0)$, $\deg(\hat{G}^{p0}) = (1,1)$, and $(1,0)\cdot(1,1) = 1$. This encodes a generalized exclusion between the transitions $0 \leftarrow 1$ and $0 \leftarrow p$.
- **Graded nilpotency (one-step constraints).** Postulates like $(\hat{G}^{ps})^2 = 0$ and $(\hat{G}^{sp})^2 = 0$ implement terminal pathways along the p–s edge (no coherent piling-up of successive $s \to p$ or $p \to s$ conversions).

These constraints function as principled "compatibility/exclusion rules'' for the ontological modes, derived from the color structure rather than imposed case by case.

4.3.1 Endogenous Super-Commutator for Holosymmetric Words

Definition 4.201 (Holosymmetric involutions and characters)**.** Let $\mathcal{H}$ be the inner automorphism group generated by (i) control-basis rotations on the control qubit and (ii) the branch-swap σ interchanging $A_G B_N \leftrightarrow A_N B_G$ (Definition 4.148, Corollary 4.168). Fix two involutive automorphisms:

$$\mathrm{Ad}_Z : X \mapsto (Z\otimes I)^\dagger X (Z\otimes I), \qquad \mathrm{Ad}_\sigma : X \mapsto \sigma(X),$$

where Z is the π rotation on the control (so that sum/difference interferometers are $\pm$ under Ad_Z and/or Ad_σ; cf. Corollary 4.168). For any holosymmetric word $W \in \mathsf{G}$, define its *endogenous charge* $q(W) = (q_c(W), q_b(W)) \in \mathbb{Z}_2^2$ by the eigenvalue equations

$$\mathrm{Ad}_Z(W) = (-1)^{q_c(W)} W, \qquad \mathrm{Ad}_\sigma(W) = (-1)^{q_b(W)} W,$$

whenever W lies in a joint eigenspace. In general, decompose W by the Reynolds projections $\Pi_{q_c,q_b} := \frac{1}{4}(I + (-1)^{q_c}\mathrm{Ad}_Z)(I + (-1)^{q_b}\mathrm{Ad}_\sigma)$ so that $W = \sum_{q\in\mathbb{Z}_2^2} W^{(q)}$ with $W^{(q)} := \Pi_q(W)$.

Remark 4.202 (Agreement with channel letters)**.** For channel letters $\hat{G}_\Lambda^{\alpha\beta}$ (Definition 4.141), the holosymmetric actions are diagonal on the fourfold modal basis; hence each letter is a joint eigenvector of $(\mathrm{Ad}_Z, \mathrm{Ad}_\sigma)$, and

$$q\big(\hat{G}_\Lambda^{\alpha\beta}\big) = \deg(\alpha) + \deg(\beta) \in \mathbb{Z}_2^2$$

(compatibly with Lemma 4.145 and Corollary 4.144). Thus the endogenous charge coincides with the traditional color on letters and, by functoriality, on typed words.

Definition 4.203 (Endogenous super-commutator)**.** For $A, B \in \mathsf{G}$, write their charge components $A = \sum_q A^{(q)}$, $B = \sum_{q'} B^{(q')}$ as in Definition 4.201. Define the *endogenous super-commutator* by

$$[A,B]_{\mathrm{endo}} := \sum_{q,q'\in\mathbb{Z}_2^2} \Big(A^{(q)} B^{(q')} \;-\; (-1)^{\langle q,q'\rangle}\, B^{(q')} A^{(q)} \Big), \tag{4.72}$$

$$\langle (a_1,a_2),(b_1,b_2)\rangle := a_1 b_1 + a_2 b_2 \pmod 2.$$

Proposition 4.204 (Graded $*$-Lie structure and covariance)**.** *The bracket* $[\,\cdot\,,\,\cdot\,]_{\mathrm{endo}}$ *satisfies:*

(a) Graded skew-symmetry and Jacobi
On joint eigenspaces it coincides with the standard $\mathbb{Z}_2^2$*-graded commutator; hence graded skew and the graded Jacobi identity hold, and by bilinearity they extend to all of* G*.*

(b) $*$-compatibility
$\big([A,B]_{\mathrm{endo}}\big)^\dagger = -\,(-1)^{\langle q(A),q(B)\rangle}\,[A^\dagger, B^\dagger]_{\mathrm{endo}}$*, with* $q(\cdot)$ *read componentwise.*

(c) Gauge covariance
Under endpoint gauge $X \mapsto g(x) X g(x')^\dagger$ *(Proposition 4.54 and Corollary 4.64),* Ad_Z *and* Ad_σ *act internally on the device factor, so charges and the bracket are preserved; thus* $[\,\cdot\,,\,\cdot\,]_{\mathrm{endo}}$ *is gauge-covariant.*

Corollary 4.205 (Selection rules and reduction)**.** *If A and B lie in joint eigenspaces with charges $q(A), q(B) \in \mathbb{Z}_2^2$, then*

$$[A,B]_{\mathrm{endo}} = \begin{cases} [A,B] & \text{if } \langle q(A), q(B)\rangle = 0, \\ \{A,B\} & \text{if } \langle q(A), q(B)\rangle = 1. \end{cases}$$

In particular, $q = (0,0)$ ("even" under both Z and σ) yields the ordinary commutator with every component. For letters $\hat{G}^{\alpha\beta}$ this reproduces Definition 4.198 and Remark 4.199 by Remark 4.202.

Remark 4.206 (Endogenous vs. graded: overlay principle)**.** The endogenous bracket uses only holosymmetric symmetries (Z, σ) and word functoriality (Definition 4.148, Proposition 4.167, and Corollary 4.168). When one *chooses* to identify $q(\cdot)$ with the bookkeeping degree $\deg(\cdot) \in \mathbb{Z}_2^2$ (Definition 4.94), one recovers the traditional graded bracket. Thus grading is an optional overlay; the sign rule is already fixed by endogeneous symmetry charges.

Remark 4.207 (Approximate symmetries and defect control)**.** If Ad_Z or Ad_σ hold only approximately (e.g. via the Reynolds projection of Theorem 4.169 with tolerance), the projections Π_q pick eigenspaces up to a defect measured by the compliance components (Δ, η, ζ) (Definition 4.178). Then

$$\big\| [A,B]_{\mathrm{endo}} - [A,B]^{\mathrm{ideal}}_{\mathrm{endo}} \big\| \;\le\; C \cdot \|\mathfrak{K}\| \, \|A\| \, \|B\|,$$

for a constant C dependent on the averaging window; in the perfect limit $\mathfrak{K} \to 0$ the ideal graded $*$-Lie structure is recovered.

Lemma 4.208 (Endogenous charges of channel letters)**.** *Let $\mathrm{Ad}_Z(X) = (Z \otimes I)^\dagger X (Z \otimes I)$ and $\mathrm{Ad}_\sigma(X) = \sigma(X)$ be the holosymmetric involutions on words (Definition 4.201), and let the fourfold selectors $\hat{\mathcal{F}}_\alpha(y)$ ($\alpha \in \{0,1,s,p\}$) be as in the words calculus (Definition 4.141, §1.2.9). Then for each α there is a charge $q(\alpha) = (q_c(\alpha), q_b(\alpha)) \in \mathbb{Z}_2^2$ with*

$$\mathrm{Ad}_Z\big(\hat{\mathcal{F}}_\alpha(y)\big) = (-1)^{q_c(\alpha)}\, \hat{\mathcal{F}}_\alpha(y), \qquad \mathrm{Ad}_\sigma\big(\hat{\mathcal{F}}_\alpha(y)\big) = (-1)^{q_b(\alpha)}\, \hat{\mathcal{F}}_\alpha(y),$$

and these charges coincide with the dialectic degrees:

$$q(\alpha) = \deg(\alpha) \in \{(0,0), (1,0), (0,1), (1,1)\}.$$

Consequently, for the channel letter $\hat{G}^{\alpha\beta}_\Lambda(x,x') = \hat{\mathcal{F}}^\dagger_\alpha(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$ one has the joint eigen-relations

$$\mathrm{Ad}_Z\big(\hat{G}^{\alpha\beta}_\Lambda\big) = (-1)^{\,q_c(\alpha)+q_c(\beta)}\; \hat{G}^{\alpha\beta}_\Lambda,$$
$$\mathrm{Ad}_\sigma\big(\hat{G}^{\alpha\beta}_\Lambda\big) = (-1)^{\,q_b(\alpha)+q_b(\beta)}\; \hat{G}^{\alpha\beta}_\Lambda,$$

so the endogenous charge of a letter is

$$q\big(\hat{G}^{\alpha\beta}_\Lambda\big) = q(\alpha) + q(\beta) = \deg(\alpha) + \deg(\beta) \in \mathbb{Z}_2^2.$$

Proof. Step 1: Selectors are joint eigen-operators. In the fourfold modal basis fixed in §1.2.9, the holosymmetric involutions act diagonally on the device degrees of freedom: Ad_Z is the control π-rotation (computational Z) and Ad_σ is the branch-swap exchanging $A_G B_N \leftrightarrow A_N B_G$ (Definition 4.148 and Corollary 4.168). By construction, each endpoint selector $\hat{\mathcal{F}}_\alpha(y)$ projects onto a fixed fourfold modal sector and is therefore a joint eigen-operator of $(\mathrm{Ad}_Z, \mathrm{Ad}_\sigma)$ with eigenvalues ± 1. We write these eigenvalue parities as $q(\alpha) = (q_c(\alpha), q_b(\alpha))$. Matching with the dialectic grading (Definition 4.94) gives

$$q(0) = (0,0), \quad q(1) = (1,0), \quad q(s) = (0,1), \quad q(p) = (1,1),$$

i.e. $q(\alpha) = \deg(\alpha)$ (control parity on the first slot, branch parity on the second).

Step 2: Transport is neutral. The geometric transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ acts on the fibre via the operational connection (Section 4.19.1) and does not involve the device involutions; hence it is neutral under both actions: $\mathrm{Ad}_Z(\mathcal{U}) = \mathcal{U}$ and $\mathrm{Ad}_\sigma(\mathcal{U}) = \mathcal{U}$.

Step 3: Letters inherit additive charges. Using multiplicativity of Ad_Z and Ad_σ and the adjoint relation $\mathrm{Ad}_\bullet(\hat{\mathcal{F}}_\alpha^\dagger) = \big(\mathrm{Ad}_\bullet(\hat{\mathcal{F}}_\alpha)\big)^\dagger$, we compute

$$\mathrm{Ad}_Z\big(\hat{G}_\Lambda^{\alpha\beta}\big) = (-1)^{q_c(\alpha)+q_c(\beta)}\, \hat{G}_\Lambda^{\alpha\beta}, \qquad \mathrm{Ad}_\sigma\big(\hat{G}_\Lambda^{\alpha\beta}\big) = (-1)^{q_b(\alpha)+q_b(\beta)}\, \hat{G}_\Lambda^{\alpha\beta}.$$

Thus $q(\hat{G}_\Lambda^{\alpha\beta}) = q(\alpha) + q(\beta)$, and with $q(\alpha) = \deg(\alpha)$ this equals $\deg(\alpha) + \deg(\beta)$, as claimed. □

Remark 4.209 (Endogenous physical postulates and analogies)**.** Within the endogenous super-commutator of Definition 4.203 and the charge assignment of Lemma 4.208:

- **Commuting (bosonic-type) sector.** Since $q(\hat{G}^{00}) = (0,0)$, Corollary 4.205 gives an ordinary commutator with every component. In particular $[\,\hat{G}^{00}, \hat{G}^{ss}\,] = 0$ by the words-level bosonic compatibility (Theorem 4.173).
- **Anticommuting (fermionic-type) mixing.** For letters with $\langle q(\hat{G}^{\alpha\beta}), q(\hat{G}^{\gamma\delta})\rangle = 1$ the bracket reduces to an anticommutator (Corollary 4.205). Example: $q(\hat{G}^{10}) = (1,0)$ and $q(\hat{G}^{p0}) = (1,1)$, so $\langle (1,0), (1,1)\rangle = 1$ and hence $\{\hat{G}^{10}, \hat{G}^{p0}\} = 0$ by the typing lemma below.
- **Graded nilpotency (one-step constraints).** The words-only nilpotency on the p–s edge, $(\hat{G}_\Lambda^{ps})^2 = (\hat{G}_\Lambda^{sp})^2 = 0$, was proven endogenously (no grading needed), cf. the words-version nilpotency theorem in the p–s section.

Thus, as in Remark 4.200, the *charges* fix *which* bracket applies, while the *values* are constrained by endogenous dynamics (centrality, bosonic compatibility, typing/orthogonality, and the p–s nilpotency).

Lemma 4.210 (Typed anticommutator vanishing: $\{\hat{G}^{10}, \hat{G}^{p0}\} = 0$)**.** *For fixed endpoints (x, x'), the channel letters $\hat{G}_\Lambda^{10}(x,x')$ and $\hat{G}_\Lambda^{p0}(x,x')$ satisfy*

$$\{\hat{G}_\Lambda^{10}(x,x'),\ \hat{G}_\Lambda^{p0}(x,x')\} = 0.$$

Proof. *By definition,* $\hat{G}^{10}_{\Lambda} = P_1(x)\,\hat{G}^{10}_{\Lambda}\,P_0(x')$ *and* $\hat{G}^{p0}_{\Lambda} = P_p(x)\,\hat{G}^{p0}_{\Lambda}\,P_0(x')$ *with orthogonal endpoint projectors* $P_1(x)P_p(x) = 0$ *(typing/selector orthogonality in Definition 4.141 and Lemma 4.145). Hence*

$$\hat{G}^{10}_{\Lambda}\hat{G}^{p0}_{\Lambda} = P_1(x)\,\hat{G}^{10}_{\Lambda}\,\underbrace{P_0(x')P_p(x)}_{=0}\,\hat{G}^{p0}_{\Lambda}\,P_0(x') = 0, \tag{4.73}$$

$$\hat{G}^{p0}_{\Lambda}\hat{G}^{10}_{\Lambda} = P_p(x)\,\hat{G}^{p0}_{\Lambda}\,\underbrace{P_0(x')P_1(x)}_{=0}\,\hat{G}^{10}_{\Lambda}\,P_0(x') = 0.$$

so their anticommutator vanishes. □

The intuition (super-commutators). A super-commutator is a compact *bookkeeping rule for interference signs.* Certain channel words behave "even" (reordering introduces no sign), while others are "odd" (reordering contributes a minus sign). When two odd contributions are swapped, the correct algebraic object is the *anticommutator*; otherwise it is the ordinary *commutator.* This sign choice is the algebraic proxy for which interference pattern—sum or difference—the setup realizes (cf. the selection rule in Corollary 4.205).

Where the sign actually comes from (endogenous view). No abstract grading needs to be postulated. The sign is *forced by two concrete holosymmetric involutions* acting on words: (i) the control π-flip Z (which toggles sum/difference interferometry), and (ii) the branch swap σ (which exchanges the two RR paths) (Definition 4.201 and Corollary 4.168). Every channel word W decomposes into joint eigensectors of these involutions; the resulting *endogenous charge* $q(W) = (q_c, q_b) \in \mathbb{Z}_2^2$ records whether W flips sign under Z and/or σ (Definition 4.201). When two words A, B are multiplied, their joint parity determines the reordering sign

$$(-1)^{\langle q(A),q(B)\rangle}, \qquad \langle (a_1,a_2),(b_1,b_2)\rangle = a_1b_1 + a_2b_2 \pmod 2,$$

and the *endogenous super-commutator*

$$[A,B]_{\text{endo}} \;=\; AB \;-\; (-1)^{\langle q(A),q(B)\rangle}BA$$

follows directly from symmetry (Definition 4.203). Identifying the charges with the usual modal colors recovers the textbook graded bracket (the *overlay principle*, Remark 4.206); the equality $q(\hat{G}^{\alpha\beta}) = \deg(\alpha) + \deg(\beta)$ is established in Lemma 4.208.

What this explains (selection rules → concrete dynamics).

- **Which bracket applies.** The charges alone decide *commutator vs. anticommutator* (Corollary 4.205); this is a kinematic, symmetry-level statement.
- **What the value is.** The actual numbers are fixed by endogenous dynamics and typing:
  - **Bosonic** $0/s$ **sector.** Since $q(\hat{G}^{00}) = (0,0)$, it commutes in the ordinary sense with every component; in particular, $[\hat{G}^{00}, \hat{G}^{ss}] = 0$ holds at the words level (Theorem 4.173).

– **"Fermionic-type" mixing.** If $\langle q(\hat{G}^{10}), q(\hat{G}^{p0})\rangle = 1$, the bracket reduces to an anticommutator; typing/orthogonality then forces $\{\hat{G}^{10}, \hat{G}^{p0}\} = 0$ (Lemma 4.210).

– $p \leftrightarrow s$ **edge.** The charge rule fixes the bracket type, while *nilpotency* $(\hat{G}^{ps})^2 = (\hat{G}^{sp})^2 = 0$ is proved purely from word composition and typing (no external grading required; see the words-version nilpotency theorem Theorem 4.170).

– **Central** ss**.** Holosymmetric invariance makes $\hat{G}^{ss}$ commute with all words (Theorem 4.169), yielding the *ss-normal form* $W \sim (\hat{G}^{ss})^m W_{\mathrm{red}}$ with W_{red} free of ss letters (Proposition 4.188).

Operational meaning (how it shows up in experiments).

- *Sum vs. difference interferometers* (control Z) and *branch-swap tests* directly resolve the two $\mathbb{Z}_2$ parities that constitute the charge q (Corollary 4.168 and Definition 4.201).
- *Commutation vs. anticommutation* manifests as *lensing equalities* and *destructive-interference constraints* in visibility envelopes predicted by the words calculus; departures in the near-ideal regime are controlled by the *compliance vector* $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178) and propagate to measurable signatures via Proposition 4.181.

Why this matters.

- The graded sign rule becomes *intrinsic*: it is a consequence of holosymmetric device symmetries, not an external axiom (Definition 4.203 and Remark 4.206).
- The construction is *gauge-stable*: charges and brackets are preserved under endpoint conjugation and parallel transport (Propositions 4.54 and 4.204 and Corollary 4.64).
- The framework remains *operational*: the same symmetries that define the algebraic sign are precisely those implemented and read out by the holosymmetric words architecture (Definition 4.148 and Proposition 4.167).

In short, the super-commutator is the algebraic shadow of two endogenous $\mathbb{Z}_2$ symmetries—control flip and branch swap—acting on holosymmetric words. The words calculus fixes the sign through symmetry charges, dynamics and typing fix the values, and the resulting predictions are measurable and robust (Definitions 4.178 and 4.203, Corollary 4.205, Theorems 4.170 and 4.173, and Propositions 4.181 and 4.188).

4.4 The Centralizing Role of Holosymmetry

Postulate 4.4 (Centralizing role of Holosymmetry)**.** *The holosymmetric self–channel is* graded–central. *Since* $\deg(\hat{G}^{ss}) = \deg(s) + \deg(s) = (0,1) + (0,1) = (0,0)$*, the graded bracket reduces to the ordinary commutator. We postulate*

$$\left[\hat{G}^{ss}(x,x'),\, \hat{G}^{\alpha\beta}(y,y')\right] \;\approx\; 0 \qquad (\forall\, \alpha,\beta). \tag{4.74}$$

More precisely, the deviation from exact centrality is controlled by the modal curvature $\mathcal{F} := \mathrm{d}\mathcal{A} + \mathcal{A} \wedge \mathcal{A}$*:*

$$\left[\hat{G}^{ss}, \hat{G}^{\alpha\beta}\right] = \mathcal{O}\left(\int_{\gamma_{x\to x'}} \|\mathcal{F}\| + \int_{\gamma_{y\to y'}} \|\mathcal{F}\|\right) + \textit{(boundary terms)}. \tag{4.75}$$

Equality in (4.74) holds (i) in the coincident/flat limit $x' \to x$, $y' \to y$ *on contractible patches where* $\mathcal{F} \equiv 0$*, and (ii) when boundary terms vanish (e.g. under standard boundary conditions). Corrections are governed by nonlocal/holonomy effects along the relevant transport paths.*

Remark 4.211 (Meaning and immediate consequences)**.** Holosymmetry (*Holothesis*) is the implementation–invariant facet; centrality states that its self–channel acts as a *coherence scalar* for the whole Fourfold algebra. Algebraically:

1. **Superselection by spectrum.** By Schur's lemma, on each irreducible representation of the graded $*$-algebra, $\hat{G}^{ss}$ is scalar: $\hat{G}^{ss} = \lambda_s \mathbb{I}$. The spectrum $\sigma(\hat{G}^{ss})$ labels holosymmetric superselection sectors; every $\hat{G}^{\alpha\beta}$ preserves them.
2. **Block preservation.** If E_λ is the projector from the spectral resolution of $\hat{G}^{ss}$, then $[E_\lambda, \hat{G}^{\alpha\beta}] = 0$ and $E_\lambda \hat{G}^{\alpha\beta} E_\lambda$ yields a consistent sectorwise reduction of the Fourfold kernel.
3. **Covariance.** Centrality is invariant under unitary gauge transport $\hat{G}^{\alpha\beta} \mapsto g\,\hat{G}^{\alpha\beta} g^\dagger$ and under the graded bracket (Section 4.3), since $\deg \hat{G}^{ss} = (0,0)$.

Physically, $\hat{G}^{ss}$ is a fixed point for the algebraic flow of dualities: it constrains how other modes may mix without itself being altered by those mixings.

Field–space nesting: geometry–matter as a coupled matrix. Beyond a single foundational field, the relational kernel must also encode geometry–matter co–dependence. Introduce the *generalized field* column

$$\hat{\mathbf{F}}(x) := \begin{pmatrix} \hat{\mathbf{\Phi}}(x) \\ \hat{\mathbf{\Theta}}(x) \end{pmatrix},$$

and define the *field–space correlator* as a 2×2 operator–valued matrix

$$\hat{\mathbf{G}}_{\text{field}}(x,x') := \begin{pmatrix} \hat{G}_{\Phi\Phi}(x,x') & \hat{G}_{\Phi\Theta}(x,x') \\ \hat{G}_{\Theta\Phi}(x,x') & \hat{G}_{\Theta\Theta}(x,x') \end{pmatrix}, \qquad \hat{G}_{AB}(x,x') = \sum_{\alpha,\beta\in\{0,1,p,s\}} \hat{G}^{\alpha\beta}_{AB}(x,x')\,\mathbf{e}_{\alpha\beta}, \tag{4.76}$$

where each block $\hat{G}_{AB}$ (with $A, B \in \{\Phi, \Theta\}$) is itself a 4×4 matrix over the dialectic basis, and $\mathbf{e}_{\alpha\beta}$ denotes the canonical mode–matrix units. Thus the full kernel is a *matrix of matrices*: 2×2 in field space, each entry 4×4 in dialectic space.

Consistency checks.

- **Hermiticity & transport.** Each $\hat{G}^{\alpha\beta}_{AB}$ obeys the same Hermitian symmetry and gauge–covariant transport as in Sections 4.1.2 and 4.1.4.

- **Field–space rotations.** For any $W(x) \in \mathrm{U}(2)$, $\hat{\mathbf{F}} \mapsto W\hat{\mathbf{F}}$ induces $\hat{\mathbf{G}}_{\mathrm{field}}(x,x') \mapsto W(x)\,\hat{\mathbf{G}}_{\mathrm{field}}(x,x')\,W(x')^{\dagger}$; dialectic indices are untouched. Centrality of the holosymmetric self–channel extends componentwise: $[\hat{G}^{ss}_{AB},\, \hat{G}^{\alpha\beta}_{CD}] \approx 0$.
- **Sector reduction.** The spectral projectors of $\hat{G}^{ss}_{AB}$ commute with all $\hat{G}^{\alpha\beta}_{CD}$, enabling a sectorwise decomposition of the full geometry–matter kernel.

Remark 4.212 (From graded–central to *endogenously* central)**.**

1. **No color flip for $\hat{G}^{ss}$.** Since $q(\hat{G}^{ss}) = (0,0)$ by Lemma 4.208, the graded sign is trivial: the graded bracket equals the ordinary commutator for $\hat{G}^{ss}$ by Corollary 4.205 and Lemma 4.95.
2. **Postulate ⇒ theorem.** The centrality postulate (4.74) is recovered as a *words-level theorem*: $[\,\hat{G}^{ss}_{\Lambda},\, X\,] = 0$ for all $X \in \mathsf{G}$ under $(\mathrm{C1}^{\mathrm{word}})$–$(\mathrm{C3}^{\mathrm{word}})$ in Theorem 4.169. Thus "graded–central" becomes *endogenously central*, with the graded sign itself explained by the device involutions Z, σ (Section 4.3.1).

Proposition 4.213 (Curvature–controlled centrality defect)**.** *Let endpoints $x, x', y, y' \in \mathcal{C}_d$ and admissible paths $\gamma_{x\to x'}$, $\gamma_{y\to y'}$. There exists a constant $C > 0$ and a curvature–holonomy functional $\Phi(\gamma)$, controlled by the connection curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$, such that*

$$\Big\| [\hat{G}^{ss}_{\Lambda}(x,x'),\, \hat{G}^{\alpha\beta}_{\Lambda}(y,y')] \Big\| \;\le\; C\Big(\Phi(\gamma_{x\to x'}) + \Phi(\gamma_{y\to y'})\Big) \;+\; \text{boundary terms.} \tag{4.77}$$

The boundary terms vanish in the coincident/flat regime (contractible patches with $\mathcal{F} \equiv 0$, and trivial endpoint dressings), by Proposition 4.59 and Section 4.19.1. Consequently, the centrality defect Δ of the compliance vector $\mathfrak{K}$ satisfies

$$\Delta \;\lesssim\; \Phi(\gamma_{x\to x'}) + \Phi(\gamma_{y\to y'}),$$

i.e. centrality defects are holonomy defects*, refining the heuristic (4.75) in §4.4 and linking directly to Definition 4.178.*

Remark 4.214 (Immediate consequences, reinterpreted endogenously)**.**

1. **Superselection by spectrum.** By $\mathcal{H}$-invariance and Theorem 4.169, $\hat{G}^{ss}_{\Lambda}$ acts as a scalar on each typed Hom-space; its spectral projectors commute with all channel words, yielding sectorwise reductions exactly as in Remark 4.211.
2. **Block preservation and covariance.** Endpoint gauge covariance, functorial transport, and block composition $\big($Propositions 4.54, 4.85 and 4.143 and Corollary 4.64$\big)$ imply that centrality is gauge-stable and is preserved under word composition, matching the structural claims of §4.4.

Proposition 4.215 (Field–space nesting and componentwise centrality)**.** *Let the field–space correlator $\hat{\mathbf{G}}_{\mathrm{field}}$ be as in (4.76). Then the holosymmetric charges $q(\cdot)$ live in the device/dialectic factor and are independent of field labels. Hence, for each $A, B, C, D \in \{\Phi, \Theta\}$,*

$$\Big[\, \hat{G}^{ss}_{AB}(x,x'),\, \hat{G}^{\alpha\beta}_{CD}(y,y') \,\Big]_{\mathrm{endo}} = 0 \quad \textit{under } (\mathrm{C1}^{\mathrm{word}})\text{–}(\mathrm{C3}^{\mathrm{word}}), \tag{4.78}$$

with the same curvature–controlled defect bound (4.77). Moreover, for any $W(x) \in \mathrm{U}(2)$, the congruence action $\hat{\mathbf{G}}_{\text{field}} \mapsto W(x)\,\hat{\mathbf{G}}_{\text{field}}\,W(x')^{\dagger}$ preserves (4.78) (since it commutes with the device involutions Z, σ). One may package defects blockwise as Δ_{AB} and aggregate (e.g. $\|\Delta\|_{\text{field}} := \max_{A,B} \Delta_{AB}$), fitting into Definitions 4.178 and 4.183.

Remark 4.216 (Editorial annotations for §4.4)**.**

1. After Postulate 4.4, append: "*Words-level derivation via $\mathcal{H}$-invariance and conditional expectation:* Theorem 4.169."
2. Replace (4.75) by a named defect bound:

$$\left\| [\hat{G}^{ss}, \hat{G}^{\alpha\beta}] \right\| \;\le\; \Delta(x, x'; y, y') \qquad \text{with } \Delta \text{ controlled by curvature/holonomy functionals of } \mathcal{F}, \tag{4.79}$$

   citing Definition 4.178 and Proposition 4.59.
3. In the "Meaning and immediate consequences" list, change "graded $*$-algebra" to "words $*$-algebra with $\mathcal{H}$-action", and cite Theorem 4.169 and Proposition 4.188 for sector reduction and the ss-normal form.

The centralizing role of holosymmetry. The centralizing role of holosymmetry in §4.4 is not merely postulated: within the endogenous words framework it is *proved* (Theorem 4.169); its deviation is quantitatively controlled by holonomy/curvature (Definition 4.178, consistent with (4.75)); and the consequences—superselection, block preservation, and field–space covariance—follow from the same $\mathcal{H}$-invariance, block composition, and gauge–covariant transport that organize the holosymmetric alphabets and words (Propositions 4.54, 4.85 and 4.143 and Corollary 4.64).

Field–space nesting (endogenous words version). Beyond a single foundational field, geometry–matter co–dependence is encoded in a field–space matrix whose entries are *holosymmetric word–evaluated* Fourfold channels.

Definition 4.217 (Endogenous field–space correlator (words–dressed))**.** Let the device (holosymmetric) alphabet and RR matrix elements be as in Definition 4.148 and eq. (4.45), and let $\hat{\mathcal{F}}_{\alpha}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x) := \mathsf{W}_{\chi_{\text{out}}\leftarrow\chi_{\text{in}}}\,\hat{\mathcal{F}}_{\alpha}(x)$ be the word–dressed selectors of Definition 4.166. For $A, B \in \{\Phi, \Theta\}$ and endpoints x, x', define the (block) field–space entries

$$\hat{G}_{AB}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x, x') \;:=\; \sum_{\alpha,\beta\in\{0,1,p,s\}} \hat{G}_{AB}^{\alpha\beta}\Big(x, x'; \mathbf{W}, \chi_{\text{out}} \leftarrow \chi_{\text{in}}\Big)\, \mathbf{e}_{\alpha\beta}, \tag{4.80}$$

where each mode coefficient is the word–evaluated channel (cf. eq. (4.66))

$$\hat{G}_{AB}^{\alpha\beta}\Big(x, x'; \mathbf{W}, \chi_{\text{out}} \leftarrow \chi_{\text{in}}\Big) := \Big(\hat{\mathcal{F}}_{\alpha}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{.in}]}(x)\Big)^{\dagger}\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_{\beta}(x') \qquad \text{placed in the } (A, B) \text{ field slot.} \tag{4.81}$$

The endogenous field–space correlator is the 2×2 operator–valued matrix

$$\hat{\mathbf{G}}_{\text{field}}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x,x') \;:=\; \begin{pmatrix} \hat{G}_{\Phi\Phi}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x,x') & \hat{G}_{\Phi\Theta}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x,x') \\ \hat{G}_{\Theta\Phi}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x,x') & \hat{G}_{\Theta\Theta}^{[\mathbf{W};\,\chi_{\text{out}}\leftarrow\chi_{\text{in}}]}(x,x') \end{pmatrix}, \tag{4.82}$$

so the full kernel is a *matrix of matrices*: 2×2 in field space, each entry 4×4 in the dialectic basis $\{\mathbf{e}_{\alpha\beta}\}$ from Definition 4.141.

Proposition 4.218 (Basic properties)**.** *For* $\hat{\mathbf{G}}_{\text{field}}^{[\mathbf{W}]}$ *of* (4.82)*:*

Gauge covariance

By Propositions 4.54 and 4.167 and Corollary 4.64, each block transforms as $\hat{G}_{AB}^{[\mathbf{W}]}(x,x') \mapsto g(x)\,\hat{G}_{AB}^{[\mathbf{W}]}(x,x')\,g(x')^{\dagger}$.

Charge (endogenous grading)

The holosymmetric charges $q(\cdot)$ *reside in the device/dialectic factor and are independent of the field labels. Consequently, the componentwise endogenous centrality statements of Proposition 4.215 apply blockwise to* $\hat{\mathbf{G}}_{\text{field}}^{[\mathbf{W}]}$.

Reduction to the undressed form

For $\mathbf{W} = I$ *and* $\chi_{\text{out}} = \chi_{\text{in}}$, (4.82) *reduces to the original field–space correlator* $\hat{\mathbf{G}}_{\text{field}}(x,x')$ *in* (4.76).

Remark 4.219 (Charge resolution and compliance)**.** Applying the Reynolds projections Π_q of Definition 4.201 yields a charge–resolved decomposition $\hat{G}_{AB}^{[\mathbf{W}]} = \sum_{q\in\mathbb{Z}_2^2} \Pi_q\big(\hat{G}_{AB}^{[\mathbf{W}]}\big)$. Centrality and its curvature–controlled defect then lift componentwise to field space as in Proposition 4.213, and can be packaged blockwise (e.g. Δ_{AB}, aggregated via $\|\Delta\|_{\text{field}} := \max_{A,B}\Delta_{AB}$), consistent with Definitions 4.178 and 4.183.

Fourfold dynamics as a holosymmetric interferometer (endogenous reading). The Fourfold dynamics may be pictured as a many–port interferometer whose "beams"—Thesis (T), Antithesis (A), Synthesis (S), and Holothesis (H)—propagate through a shared device. In the endogenous calculus, this picture is made precise by the *channel alphabet and words* (Definition 4.141), together with holosymmetric device operations that realize sum/difference interferometry and branch exchange (Definition 4.148 and Corollary 4.168). Here T/A/S/H describe *traffic*—which modal branches are populated and whether they coexist coherently—while the holosymmetric actions specify the *wiring diagram* that steers and recombines those branches within words.

Central holosymmetry as a global coherence meter. The "coherence meter" of the apparatus is the holosymmetric self–channel, whose centralizing role is not merely postulated but *derived* in the words framework: under the endogenous hypotheses $(\mathrm{C1}^{\text{word}})$–$(\mathrm{C3}^{\text{word}})$ one has $[\,\hat{G}_{\Lambda}^{ss},\,X\,] = 0$ for all words $X \in \mathsf{G}$ (Theorem 4.169). Algebraically, centrality means commuting with everything; operationally, it means acting as a *coherence scalar* that multiplies processes without being distorted by their internal rearrangements (Remark 4.211). This endogenizes the intuition that the holosymmetric diagonal provides a fixed reference frame against which all other couplings unfold, and it underpins the *ss-normal form* $W \sim (\hat{G}^{ss})^m W_{\text{red}}$ (Proposition 4.188).

Sectors and local mixing. Because $\hat{G}^{ss}_{\Lambda}$ commutes with the entire words algebra, its spectral projectors commute with all channels, partitioning dynamics into *holosymmetric superselection sectors* (Remark 4.211 and Theorem 4.169). Within a fixed sector, the remaining modes (T/A/S/H) may mix and interfere according to the endogenous bracket and typing rules (Definition 4.203, Corollary 4.205, and Lemma 4.145); crossings between sectors, by contrast, correspond to genuine changes of the global architecture rather than local switches. In this sense, holosymmetry labels the "universe of implementation'' while leaving intra–sector dynamics intact.

When centrality fails: curvature and holonomy. Perfect centrality can fail only when global features of the transporter announce themselves. The words calculus quantifies this via a *curvature/holonomy* control:

$$\left\| [\hat{G}^{ss}_{\Lambda}(x,x'),\, \hat{G}^{\alpha\beta}_{\Lambda}(y,y')] \right\| \;\le\; C(\Phi(\gamma_{x\to x'}) + \Phi(\gamma_{y\to y'})) + \text{boundary terms},$$

where Φ is a holonomy functional determined by the curvature $\mathcal{F}$ (Proposition 4.213). Thus the "calibration tone'' wobbles only when transport explores nontrivial loops; in the flat/coincident limit the commutator vanishes exactly (Proposition 4.59). This matches the defect bookkeeping provided by the *holosymmetric compliance vector* $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178).

The prism of interrogations: local facets vs. whole–system invariants. The Fourfold "prism'' cleanly separates: (i) *local resolution* (T/A occupancy and their interference), (ii) *coherent coexistence* (S–type contributions inside words), and (iii) *whole–system invariants* (the holosymmetric ss diagonal). Endogenous centrality guarantees that the reading of "structure at the whole'' is consistent regardless of which local facet is interrogated first (Theorem 4.169 and Proposition 4.188). Experimentally, the two $\mathbb{Z}_2$ involutions—control Z and branch swap σ—select the interference signs (charges) and thereby fix whether commutators or anticommutators are the correct comparisons (Definition 4.201 and Corollaries 4.168 and 4.205). Deviations from ideal behavior translate into bounded shifts in visibility/lensing diagnostics via the compliance map (Definition 4.178 and Proposition 4.181).

Intuitive summary. Holosymmetry is the fixed reference of the endogenous architecture—a coherence ledger for the entire mechanism. It constrains and normalizes other channels without being perturbed by their internal dynamics, except when genuinely global features (holonomy/curvature) intervene (Proposition 4.213). In the words calculus, this narrative is not merely metaphorical: it is encoded by centrality at the algebraic level (Theorem 4.169), sector decomposition (Remark 4.211), normal forms (Proposition 4.188), and symmetry–selected brackets (Definition 4.203 and Corollary 4.205), all organized by gauge–covariant transport and block composition (Propositions 4.54, 4.85 and 4.143 and Corollary 4.64).

4.5 Holosymmetric Wordwise Covariant Kinematics (Along a Path)

Fix a device-level word $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ and a control transition $\chi_{\mathrm{in}} \to \chi_{\mathrm{out}}$. Recall the RR matrix element $\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}}$ (Definition 4.148 and eq. (4.45)) and the corresponding *word-evaluated channel* components

$$\hat{G}^{\alpha\beta}_{\Lambda}(x, x'; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}) = \Big(\hat{\mathcal{F}}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\alpha}(x)\Big)^{\dagger} \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_{\beta}(x') \tag{4.83}$$

(see Definition 4.166 and eq. (4.66)).

Throughout we use the transport connection $\mathcal{A}$ ($\mathcal{U} = \mathcal{P}\exp\!\big(-\int_{\gamma} \mathcal{A}\big)$, Definition 4.48 and eqs. (4.11) and (4.12)) and the endpoint gauge laws for channels (Proposition 4.54 and Corollary 4.64).

Definition 4.220 (Wordwise covariant derivative)**.** For each component $\hat{G}^{\alpha\beta}(\cdot; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}})$, define the *wordwise* covariant derivative (w.r.t. the first endpoint x)

$$\mathbb{D}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\mu} \hat{G}^{\alpha\beta} \;:=\; \partial_{\mu} \hat{G}^{\alpha\beta} \;+\; \big[\, \mathcal{A}_{\mu},\; \hat{G}^{\alpha\beta} \,\big]. \tag{4.84}$$

Lemma 4.221 (Gauge covariance and typing preservation)**.** *Under an endpoint gauge $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$,*

$$\mathcal{A}_{\mu} \mapsto g \mathcal{A}_{\mu} g^{\dagger} + (\partial_{\mu} g) g^{\dagger}, \qquad \hat{G}^{\alpha\beta} \mapsto g(x)\, \hat{G}^{\alpha\beta}\, g(x')^{\dagger},$$

and

$$\mathbb{D}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\mu} \hat{G}^{\alpha\beta} \;\mapsto\; g(x) \Big(\mathbb{D}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\mu} \hat{G}^{\alpha\beta}\Big)\, g(x')^{\dagger}.$$

Moreover, the endpoint typing $(\alpha, x) \to (\beta, x')$ is unchanged by $\mathbb{D}^{[\cdot]}_{\mu}$ since the commutator acts by conjugation on the RR space while respecting the letter typing rules (Propositions 4.143 and 4.167).

Proof. Direct substitution of the gauge laws (Proposition 4.54 and Corollary 4.64) into (4.84); typing preservation follows because the commutator with an even (connection) element does not alter the letter endpoints and admissible concatenations. □

Lemma 4.222 (Wordwise Leibniz rule)**.** *Let $X(\cdot; \mathbf{W}_1)$, $Y(\cdot; \mathbf{W}_2)$ be word-evaluated channels whose concatenation is admissible (Definition 4.141). Then*

$$\mathbb{D}^{[\mathbf{W}_2 \mathbf{W}_1]}_{\mu}\big(XY\big) = \big(\mathbb{D}^{[\mathbf{W}_1]}_{\mu} X\big) Y + X \big(\mathbb{D}^{[\mathbf{W}_2]}_{\mu} Y\big).$$

Proof. Expand $\partial_{\mu}(XY)$ and use that $[\,\mathcal{A}_{\mu}, XY\,] = [\,\mathcal{A}_{\mu}, X\,]Y + X[\,\mathcal{A}_{\mu}, Y\,]$, with admissibility of word concatenation provided by typing rules (Proposition 4.143). □

Proposition 4.223 (Wordwise parallel consistency along a path)**.** *Let $\gamma : [s_0, s_1] \to \mathcal{X}_q$ with $\gamma(s_0) = x'$, $\gamma(s_1) = x$ and $A_{\gamma}(s) = (\gamma^{*}\mathcal{A})_s(\dot{\gamma}(s))$ (eq. (4.10)). Assume* word-locked selectors *at the readout end:*

$$\partial_s \Big(\hat{\mathcal{F}}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\alpha}\big(\gamma(s)\big)\Big)^{\dagger} + \Big[A_{\gamma}(s),\; \Big(\hat{\mathcal{F}}^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}_{\alpha}\big(\gamma(s)\big)\Big)^{\dagger}\Big] = 0.$$

Then for $\hat{G}^{\alpha\beta}\big(\gamma(s), x'; \mathbf{W}, \chi_{\text{out}} \leftarrow \chi_{\text{in}}\big)$ *one has the* parallel consistency ODE

$$\Big(\partial_s + [A_\gamma(s), \cdot\,]\Big)\hat{G}^{\alpha\beta}\big(\gamma(s), x'; \mathbf{W}, \chi_{\text{out}} \leftarrow \chi_{\text{in}}\big) = 0.$$

Proof. Differentiate the defining product and use the transport ODE $\partial_s \mathcal{U} = -A_\gamma(s)\mathcal{U}$ (eq. (4.12)), the word-lock condition at the readout end, and Lemma 4.222 for derivation property. All terms cancel pairwise. □

Proposition 4.224 (Wordwise curvature identity)**.** *For any word-evaluated channel* $X(\cdot; \mathbf{W})$*,*

$$\big[\mathbb{D}_\mu^{[\mathbf{W}]},\ \mathbb{D}_\nu^{[\mathbf{W}]}\big]X = \big[\,\mathcal{F}_{\mu\nu},\ X\,\big], \qquad \mathcal{F}_{\mu\nu} = \partial_\mu \mathcal{A}_\nu - \partial_\nu \mathcal{A}_\mu + [\mathcal{A}_\mu, \mathcal{A}_\nu]$$

(Definition 4.56). If $\mathcal{F} = 0$ *on a simply connected neighbourhood, the parallel consistency of Proposition 4.223 integrates to word–path independence up to endpoint gauge (Proposition 4.59).*

Proof. Compute using (4.84); the connection enters only through ordinary commutators, so the standard curvature identity applies. Integrability and endpoint gauge covariance give path independence. □

Corollary 4.225 (Compatibility with Hadamard sum/difference)**.** *For the symmetric interferometer choice* $\mathbf{U}_{\text{Had}}$ *(Definition 2.123), the Hadamard-induced decomposition of RR elements into sum/difference histories (Corollary 4.168) is preserved by the wordwise derivative:*

$$\mathbb{D}_\mu^{[\mathbf{U}_{\text{Had}}]}\hat{G}_\Lambda^{\alpha\beta}(\cdot; \mathbf{U}_{\text{Had}}, \chi \leftarrow \chi) = \tfrac{1}{2}\Big(\mathbb{D}_\mu^{[\cdot]}\hat{G}_+^{\alpha\beta} + \mathbb{D}_\mu^{[\cdot]}\hat{G}_-^{\alpha\beta}\Big),$$

where $\hat{G}_\pm^{\alpha\beta}$ *are the channels built from the* $\pm$ *combinations of the two lifted histories (Definition 4.148).*

Remark 4.226 (Endogenous vs. graded kinematics)**.** The wordwise derivative (4.84) is the endogenous counterpart of $\mathfrak{D}_\mu$ in Definition 4.134. It avoids the graded overlay: no supercommutator is needed—letters carry typing, and $\mathcal{A}_\mu$ is even—yet Lemmas 4.221 and 4.222 and Proposition 4.224 mirror Lemmas 4.135 and 4.136 and Proposition 4.138. In particular, flatness implies word–path independence (Proposition 4.59), and parallel consistency along γ is exactly Proposition 4.223.

4.6 Emergent Inner Product Structure of Modal Hilbert Spaces

Standing GNS framework and notation. By Definition 1.34, the Holo-State $\omega^{\overset{\circ}{\mathbf{\Psi}}} : \mathcal{A} \to \mathbb{C}$ induces a GNS triple $(\pi_{\overset{\circ}{\mathbf{\Psi}}},\ \mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}},\ |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle)$. We set $\mathcal{H}_{\text{em}} := \mathcal{H}_{\overset{\circ}{\mathbf{\Psi}}}$ and adopt the represented-operator convention: for any $A \in \mathcal{A}$, $\hat{A} := \pi_{\overset{\circ}{\mathbf{\Psi}}}(A) \in \mathcal{B}(\mathcal{H}_{\text{em}})$, with expectations $\omega^{\overset{\circ}{\mathbf{\Psi}}}(A) = \langle\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}|\ \hat{A}\ |\Omega_{\omega^{\overset{\circ}{\mathbf{\Psi}}}}\rangle$. All field modes $\hat{\mathcal{F}}_\alpha$, channel kernels $\hat{G}_\Lambda^{\alpha\beta}(x, x')$, and the transporter $\mathcal{U}(x \leftarrow$

$x';\gamma) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}})$ act on $\mathcal{H}_{\mathrm{em}}$, with $\hat{G}_\Lambda^{\alpha\beta}$ defined from selectors and transport as in Definition 4.61 and $\mathcal{U}$ given by the parallel–transport constructions Definitions 4.48 and 4.49 (cf. gauge covariance in Proposition 4.54 and Corollary 4.64).

Endogenous augmentation (holosymmetric words). In the holosymmetric words framework, device words $\mathbf{W}$ from Definition 4.148 act on the RR factor to dress the selectors via their RR matrix elements $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ (eq. (4.45)), producing word–dressed selectors

$$\hat{\mathcal{F}}_\alpha^{[\mathbf{W};\,\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}]}(x) := \mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}\,\hat{\mathcal{F}}_\alpha(x) \quad (\textit{Definition } 4.166).$$

The corresponding *word–evaluated channels* are

$$\hat{G}_\Lambda^{\alpha\beta}\Big(x,x';\mathbf{W},\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}\Big) := \Big(\hat{\mathcal{F}}_\alpha^{[\mathbf{W};\,\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}]}(x)\Big)^\dagger\,\mathcal{U}(x\leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x') \quad (\textit{eq. } (4.66)),$$

which reduce to the undeformed $\hat{G}_\Lambda^{\alpha\beta}(x,x')$ when $\mathbf{W}=I$ and $\chi_{\mathrm{out}}=\chi_{\mathrm{in}}$. Gauge covariance, adjoint symmetry, and degree additivity are preserved under dressing (Proposition 4.167) and under word formation from the channel alphabet (Definition 4.141 and Proposition 4.143). Typing, block composition through intermediate loci, and endpoint–degree rules hold verbatim for words (Proposition 4.85, Lemma 4.145, and Corollary 4.144).

Commutation relations are taken with the *endogenous super–commutator* (Definition 4.203); the bracket type (commutator vs. anticommutator) is fixed by the holosymmetric charges and the selection rule $\langle q(\cdot), q(\cdot)\rangle$ (Corollary 4.205). Words–level centrality, bosonic $0/s$ compatibility, and $p\leftrightarrow s$ nilpotency then apply to these operators acting on $\mathcal{H}_{\mathrm{em}}$ (Theorems 4.169, 4.170 and 4.173), with curvature/holonomy–controlled defects packaged by the compliance vector $\mathfrak{K}$ (Definition 4.178).

Assumption 4.227 (Holo-State and representation backdrop)**.** *Throughout this section, $\omega^{\mathring{\mathbf{\Psi}}}$ is a positive, normalized state on $\mathcal{A}$ with GNS triple $(\pi_{\mathring{\mathbf{\Psi}}}, \mathcal{H}_{\mathring{\mathbf{\Psi}}}, |\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle)$ as provided by Definition 1.34. We identify $\mathcal{H}_{\mathrm{em}} := \mathcal{H}_{\mathring{\mathbf{\Psi}}}$, write $\hat{A} := \pi_{\mathring{\mathbf{\Psi}}}(A)$, and abbreviate $\langle\mathring{\mathbf{\Psi}}|\cdot|\mathring{\mathbf{\Psi}}\rangle = \langle\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}|\cdot|\Omega_{\omega^{\mathring{\mathbf{\Psi}}}}\rangle = \omega^{\mathring{\mathbf{\Psi}}}(\cdot)$ on $\mathcal{A}$. In particular, the modal operators and channels act on $\mathcal{H}_{\mathrm{em}}$ as in Definitions 4.48, 4.49 and 4.61, and transform covariantly under endpoint gauge by Proposition 4.54 and Corollary 4.64.*

Definition 4.228 (Emergent inner product on a modal fiber)**.** Let x label a PQS locus and let $|\psi_i\rangle_x \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ be modal states (Definition 4.273). The inner product on the fiber at x is *defined* from the Fourfold Inter-Modal Correlator (Definition 4.9) by

$$\boxed{\langle\psi_1|\psi_2\rangle_x := \lim_{x'\to x}\Big\langle\mathring{\mathbf{\Psi}}\Big|\,\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle = \lim_{x'\to x}\omega^{\mathring{\mathbf{\Psi}}}(G_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2])\,.} \tag{4.85}$$

Assumption 4.229 (Regularity near the diagonal)**.** *The map $(x,x')\mapsto\hat{G}_\Lambda^{\alpha\beta}(x,x')$ is continuous in a neighborhood of the diagonal $\{(x,x) : x\in\mathcal{X}_q\}$ (in operator norm or weak operator topology), and the parallel transporter $\mathcal{U}(x\leftarrow x';\gamma)$ is unitary and continuous in (x,x'). These conditions ensure the existence of the limit in (4.85).*

Theorem 4.230 (Regularity near the diagonal for channel kernels)**.** *Let* $\hat{G}_\Lambda^{\alpha\beta}(x,x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x\leftarrow x';\gamma_{x\to x'})\,\hat{\mathcal{F}}_\beta(x')$ *be the Fourfold channel of Definition 4.61, with transporter* $\mathcal{U}$ *defined by Definitions 4.48 and 4.49. Assume the selector fields* $x\mapsto\hat{\mathcal{F}}_\alpha(x)$ *are operator–norm continuous on* $\mathcal{X}_q$*, uniformly bounded on compact sets, and that the operational connection of Section 4.19.1 is locally bounded with continuous curvature.*

Then:

(1) Unitarity and continuity of transport

For each admissible path $\gamma_{x\to x'}$*,* $\mathcal{U}(x\leftarrow x';\gamma_{x\to x'})$ *is unitary and depends continuously on* (x,x') *(in operator norm on compact sets); see Definition 4.49 and the Grönwall–type stability that follows from the local boundedness of the connection.*

(2) Near–diagonal continuity of $\hat{G}_\Lambda^{\alpha\beta}$

The map $(x,x')\mapsto\hat{G}_\Lambda^{\alpha\beta}(x,x')$ *is operator–norm continuous in a neighborhood of the diagonal* $\{(x,x):x\in\mathcal{X}_q\}$*. Hence, for any net* $(x_\nu,x'_\nu)\to(x,x)$*,*

$$\left\|\,\hat{G}_\Lambda^{\alpha\beta}(x_\nu,x'_\nu)-\hat{G}_\Lambda^{\alpha\beta}(x,x)\,\right\|\;\longrightarrow\;0.$$

(3) Existence of the coincident limit

The regulated coincident limit used in the emergent inner–product construction exists:

$$\lim_{(x',x)\to(x,x)}\;\langle\psi,\;\hat{G}_\Lambda^{\alpha\beta}(x,x')\,\phi\rangle\quad\textit{exists for all }\psi,\phi\in\mathcal{H}_{\mathrm{em}},$$

and coincides with the operator–norm limit from (2), thus justifying the use of (4.85) in §4.6.

Moreover, all statements are stable under endpoint gauge conjugation by $\hat{G}_\Lambda^{\alpha\beta}\mapsto g(x)\hat{G}_\Lambda^{\alpha\beta}g(x')^\dagger$ *(Proposition 4.54 and Corollary 4.64).*

Proof. (1) Unitarity follows from the ODE characterization with skew–Hermitian generator ($\dot{\mathcal{U}}=-\mathcal{A}(\dot\gamma)\mathcal{U}$) in Definition 4.49, which yields $\frac{d}{dt}\big(\mathcal{U}^\dagger\mathcal{U}\big)=0$. Continuity in (x,x') along a canonical local family of admissible paths follows from standard integral–equation stability and the local boundedness of the connection in Section 4.19.1.

(2) Write

$$\hat{G}_\Lambda^{\alpha\beta}(x,x')=\hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x\leftarrow x';\gamma_{x\to x'})\,\hat{\mathcal{F}}_\beta(x').$$

Each factor is operator–norm continuous by hypothesis (selectors) and by (1) (transport). Uniform boundedness on compact neighborhoods is ensured by the spectral restriction $\mathfrak{F}_x=\operatorname{Ran}E^{(x)}([0,\lambda_{\mathrm{cutoff}}])$ (eq. (4.303)), so the product map is operator–norm continuous.

(3) The operator–norm continuity implies strong and weak operator continuity; thus the limit (4.85) exists and equals the operator–norm limit. Gauge stability is inherited from Proposition 4.54 and Corollary 4.64. □

Corollary 4.231 (Words–dressed regularity)**.** *For word–dressed selectors and channels of Definition 4.166 and eq. (4.66),*

$$\hat{G}_\Lambda^{\alpha\beta}\big(x,x';\mathbf{W},\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}\big)=\Big(\hat{\mathcal{F}}_\alpha^{[\mathbf{W};\,\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}]}(x)\Big)^\dagger\,\mathcal{U}(x\leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x'),$$

the map $(x, x') \mapsto \hat{G}_\Lambda^{\alpha\beta}(\cdots)$ is operator–norm continuous near the diagonal, and the coincident limit exists as in (4.85). Gauge covariance and adjoint/degree properties are preserved by Proposition 4.167.

Corollary 4.232 (Compatibility with channel words)**.** *Let W be any channel word in the sense of Definition 4.141. The map $(x, x') \mapsto W(x, x')$ obtained by block composition through intermediate loci (Propositions 4.85 and 4.143) is operator–norm continuous near the diagonal, and its coincident limit exists in the sense of (4.85).*

Remark (strength relative to the original assumption). Theorem 4.230 replaces Assumption 4.229. In particular, the existence of the emergent inner-product limit is now a consequence of: (i) the ODE/parallel-transport framework (Definitions 4.48 and 4.49 and Section 4.19.1), (ii) selector continuity and spectral localization (eq. (4.303)), and (iii) gauge covariance (Proposition 4.54 and Corollary 4.64). The words-level extensions (Definitions 4.141 and 4.166 and Proposition 4.167) show that the result is robust under holosymmetric dressing and composition.

Proposition 4.233 (Well-posedness of the fiber inner product)**.** *Under Assumption 4.227 and the near-diagonal regularity of Theorem 4.230, the sesquilinear form $\langle\cdot|\cdot\rangle_x$ defined by the coincident-limit prescription (4.85) is antilinear in the first argument, linear in the second, Hermitian $\langle\psi_1|\psi_2\rangle_x = \overline{\langle\psi_2|\psi_1\rangle_x}$, and positive semidefinite. Quotienting by its null space and completing yields a Hilbert space, denoted again $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$.*

Proof. Setup. For fixed $x \in \mathcal{X}_q$, define the limiting operator

$$K_x \;:=\; \lim_{(x',x)\to(x,x)} \hat{G}_\Lambda(x, x') \quad \text{in operator norm,}$$

whose existence follows from Theorem 4.230. Here $\hat{G}_\Lambda(x, x')$ stands for the (modal) channel kernel built from selectors and transport as in Definition 4.61, i.e. $\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\,\mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}_\beta(x')$, with $\mathcal{U}$ as in Definitions 4.48 and 4.49. Define

$$\langle\psi_1|\psi_2\rangle_x \;:=\; \langle\psi_1,\, K_x\,\psi_2\rangle_{\mathcal{H}_{\mathrm{em}}} \qquad (\psi_1, \psi_2 \in \mathcal{H}_{\mathrm{em}}).$$

Sesquilinearity. For each (x, x'), the map $(\psi_1, \psi_2) \mapsto \langle\psi_1,\, \hat{G}_\Lambda(x, x')\,\psi_2\rangle$ is antilinear in ψ_1 and linear in ψ_2. Passing to the operator-norm limit preserves sesquilinearity; hence $\langle\cdot|\cdot\rangle_x$ is antilinear/linear in its arguments.

Hermiticity. By the channel Hermitian symmetry $(\hat{G}_\Lambda^{\alpha\beta}(x, x'))^\dagger = \hat{G}_\Lambda^{\beta\alpha}(x', x)$ (Lemma 4.66 and Proposition 4.52), $\hat{G}_\Lambda(x, x')^\dagger = \hat{G}_\Lambda(x', x)$. Taking the near-diagonal limit in operator norm yields $K_x^\dagger = K_x$, so $\langle\psi_1|\psi_2\rangle_x = \overline{\langle\psi_2|\psi_1\rangle_x}$.

Positive semidefiniteness. Write the selector column $\mathcal{F}(x) := \big(\hat{\mathcal{F}}_0(x), \hat{\mathcal{F}}_1(x), \hat{\mathcal{F}}_s(x), \hat{\mathcal{F}}_p(x)\big)$ as an operator $\mathcal{H}_{\mathrm{em}} \to \mathcal{H}_{\mathrm{em}}^{\oplus 4}$. In the coincident/flat limit, $\mathcal{U}(x \leftarrow x;\gamma) = I$ (Proposition 4.59), hence

$$K_x \;=\; \lim_{x'\to x} \hat{G}_\Lambda(x, x') \;=\; \sum_{\alpha,\beta} \hat{\mathcal{F}}_\alpha^\dagger(x)\,\delta_{\alpha\beta}\,\hat{\mathcal{F}}_\beta(x) \;=\; \mathcal{F}(x)^\dagger\,\mathcal{F}(x).$$

Therefore, for any $\psi \in \mathcal{H}_{\mathrm{em}}$, $\langle\psi|\psi\rangle_x = \langle\psi,\, \mathcal{F}(x)^\dagger\mathcal{F}(x)\,\psi\rangle = \|\mathcal{F}(x)\psi\|^2 \geq 0$, establishing positive semidefiniteness. (The equality with the near-diagonal limit is ensured by Theorem 4.230.)

Quotient and completion. Let $\mathcal{N}_x := \{\psi : \langle\psi|\psi\rangle_x = 0\}$ be the null space. The Cauchy–Schwarz inequality holds for positive semidefinite sesquilinear forms; thus $\langle\cdot|\cdot\rangle_x$ descends to a genuine inner product on the quotient $\mathcal{H}_{\mathrm{em}}/\mathcal{N}_x$. Completing this pre-Hilbert space yields a Hilbert space, denoted $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$.

Gauge covariance (well-posedness). Under endpoint gauge (Proposition 4.54 and Corollary 4.64), the transformations are:

$$\begin{aligned} \hat{G}_\Lambda(x,x') &\mapsto g(x)\hat{G}_\Lambda(x,x')g(x')^\dagger \\ \text{whence } K_x &\mapsto g(x)K_x g(x)^\dagger. \end{aligned} \tag{4.86}$$

The quadratic form

$$\langle\psi_1|\psi_2\rangle_x = \langle\psi_1, K_x\psi_2\rangle$$

is gauge-invariant, so the construction is well posed on the fiber.

All claims follow. □

Remark 4.234 (Words-dressed extension)**.** For word-dressed channels $\hat{G}_\Lambda^{\alpha\beta}(\cdots;\mathbf{W})$ (Definition 4.166 and eq. (4.66)), Theorem 4.230 and Corollary 4.231 ensure the coincident-limit operator $K_x^{[\mathbf{W}]}$ exists and remains positive: $K_x^{[\mathbf{W}]} = \mathcal{F}^{[\mathbf{W}]}(x)^\dagger\mathcal{F}^{[\mathbf{W}]}(x)$ with $\mathcal{F}^{[\mathbf{W}]}(x) := \left(\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x)\right)_\alpha$. Thus the same proof yields a well-posed inner product and the same fiber Hilbert space.

Status and geometry of the emergent spaces (endogenous strengthening).

Definition 4.235 (Modal bundle over $\mathcal{X}_q$)**.** Let $\mathcal{X}_q$ be the emergent configuration space of eq. (4.322). For each class $\mathfrak{B}_x$ (anchor $x \in \mathcal{X}_q$), let $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ be the fiber Hilbert space obtained from the coincident-limit inner product $\langle\cdot|\cdot\rangle_x$ in eq. (4.85) and Proposition 4.233. Define the total space and projection

$$\mathscr{H}_{\mathrm{mod}} := \bigsqcup_{x\in\mathcal{X}_q} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}, \qquad \pi_{\mathrm{mod}} : \mathscr{H}_{\mathrm{mod}} \longrightarrow \mathcal{X}_q, \quad \pi_{\mathrm{mod}}(\psi) = x \ \text{ if } \ \psi \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}.$$

Then $(\mathscr{H}_{\mathrm{mod}}, \pi_{\mathrm{mod}})$ is a (locally trivial) Hermitian Hilbert bundle, with typical fiber isomorphic to the completion of $\mathcal{H}_{\mathrm{em}}/\mathcal{N}_x$ as in Proposition 4.233. Local trivializations are provided by the operational transporter of Section 4.19.1 in the regime of Theorem 4.230; the structure group acts by fiberwise unitaries (cf. Proposition 4.54 and Corollary 4.64).

Proposition 4.236 (Fiber metric is generated by correlators)**.** *For each $x \in \mathcal{X}_q$, let $K_x := \lim_{(x',x)\to(x,x)} \hat{G}_\Lambda(x,x')$ (operator-norm limit) as in Theorem 4.230. Then the fiber inner product is*

$$\langle\psi_1|\psi_2\rangle_x \;=\; \langle\psi_1,\; K_x\,\psi_2\rangle_{\mathcal{H}_{\mathrm{em}}} \qquad (\psi_1,\psi_2 \in \mathcal{H}_{\mathrm{em}}),$$

Hermitian and positive semidefinite (Proposition 4.233). In the flat/coincident regime (Proposition 4.59), $K_x = \mathcal{F}(x)^\dagger\mathcal{F}(x)$ with $\mathcal{F}(x) = (\hat{\mathcal{F}}_0(x), \hat{\mathcal{F}}_1(x), \hat{\mathcal{F}}_s(x), \hat{\mathcal{F}}_p(x))$, so

$$\langle\psi|\psi\rangle_x = \|\mathcal{F}(x)\psi\|^2,$$

making the induced metric state- and transport-aware *via $\omega^{\mathring{\Psi}}$ and the operational connection (Assumption 4.227 and Section 4.19.1).*

Proposition 4.237 (Local triviality, metric compatibility, and holonomy defect)**.** *Let* $\gamma : [0,1] \to \mathcal{X}_q$ *be an admissible curve with parallel transport* $\mathcal{U}_\gamma$ *of Definitions 4.48 and 4.49. Then on a simply connected flat neighborhood* ($\mathcal{F} \equiv 0$) *one has*

$$K_{\gamma(1)} \;=\; \mathcal{U}_\gamma\, K_{\gamma(0)}\, \mathcal{U}_\gamma^\dagger, \quad \textit{hence} \quad \langle \mathcal{U}_\gamma \psi_1 \,|\, \mathcal{U}_\gamma \psi_2 \rangle_{\gamma(1)} = \langle \psi_1 \,|\, \psi_2 \rangle_{\gamma(0)}.$$

Thus parallel transport gives unitary identifications *of nearby fibers (metric compatibility). In the curved case,*

$$\left\| K_{\gamma(1)} - \mathcal{U}_\gamma\, K_{\gamma(0)}\, \mathcal{U}_\gamma^\dagger \right\| \;\le\; C\, \Phi(\gamma),$$

with holonomy functional Φ *controlled by the curvature* $\mathcal{F}$ *(non-Abelian Stokes–type stability), i.e. metric non-parallelism is* bounded by holonomy *(Proposition 4.213).*

Remark 4.238 (Fourfold roles encoded in the fiber metric)**.** Decompose K_x into modal blocks using the channel alphabet (Definition 4.141):

$$K_x \;=\; \sum_{\alpha} \hat{\mathcal{F}}_\alpha^\dagger(x) \hat{\mathcal{F}}_\alpha(x) \;+\; \sum_{\alpha \neq \beta} \hat{\mathcal{F}}_\alpha^\dagger(x) \hat{\mathcal{F}}_\beta(x).$$

The diagonal terms encode *modal persistence* (occupancy), while off-diagonal terms encode *transitions/interference*. At words level, the $0/s$ diagonal refinements of triadic geometry split the diagonal contributions by sector (Proposition 4.187); central holosymmetry yields ss-normal forms that factor out a commuting "coherence scalar" (Theorem 4.169 and Proposition 4.188); and the $p \leftrightarrow s$ edge constraints (nilpotency) suppress multiple-step interference in those channels (Theorem 4.170). Departures in curved regimes are quantitatively controlled by the compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definitions 4.178 and 4.183).

Principle of an emergent inner product (conceptual upshot, formalized). The fiber inner product is a *derived observable*:

$$\langle \psi_1 | \psi_2 \rangle_x \;=\; \omega^{\mathring{\mathbf{\Psi}}}\Big(\langle \psi_1 |\, \hat{G}_\Lambda(x,x')\, | \psi_2 \rangle \Big)\Big|_{(x',x)\to(x,x)}$$

(by Assumption 4.227 and Theorem 4.230; see also Proposition 4.233). (4.87)

Thus the probabilistic geometry of each fiber is fixed by the global, entangled architecture encoded in the Holo-State and transported by the operational connection (Section 4.19.1). In flat, commuting regimes ($\mathcal{F} \equiv 0$, central holosymmetry exact), the construction reduces to the classical dyad's metric on the diagonal sector (Proposition 4.187); when coherence and global structure matter, the full Fourfold content and its words-level symmetries determine the metric and its sectoral decomposition (Definition 4.203, Corollary 4.205, and Theorem 4.169).

4.6.1 Hilbert Bundle of Dialectic Modes over the Emergent Configuration Space

Building on the Primordial Quantum Singularity $\mathfrak{B}_x$ (Definition 1.25; cf. the PQS continuum Definition 4.617) and its emergent modal fiber $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$, whose inner product is generated by the Fourfold correlator (Section 4.6, eq. (4.85), and Proposition 4.233), we now organize these fibers over the emergent quantum configuration space $\mathcal{X}_q$ (Proposition 4.625) into a geometric bundle.

Definition 4.239 (Hilbert bundle of dialectic modes)**.** Let $\mathcal{X}_q$ be the emergent configuration space (eq. (4.322)). To each $x \in \mathcal{X}_q$ associate a PQS $\mathfrak{B}_x$ and its modal fiber $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ (a four-dimensional complex Hilbert space once the inner product is fixed by eq. (4.85) and Proposition 4.233). The *Hilbert bundle of dialectic modes* is the triple $(\mathscr{H}_{\mathrm{mod}}, \pi, \mathcal{X}_q)$ with

$$\boxed{\mathscr{H}_{\mathrm{mod}} := \bigsqcup_{x\in\mathcal{X}_q} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}, \qquad \pi : \mathscr{H}_{\mathrm{mod}} \to \mathcal{X}_q, \quad \pi^{-1}(x) = \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4.} \tag{4.88}$$

After eq. (4.85) is established, choose unit representatives of the realized rays $\mathcal{R}_x(\alpha) \subset \mathbb{P}(\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)})$ for $\alpha \in \{0, 1, p, s\}$ to obtain an orthonormal ordered frame

$$\mathcal{B}_x := \{|0\rangle_x,\ |1\rangle_x,\ |p\rangle_x,\ |s\rangle_x\}, \qquad \langle\alpha_x|\beta_x\rangle = \delta_{\alpha\beta}.$$

Here $|0\rangle_x, |1\rangle_x$ are the Symmetry/Antisymmetry (dyad) modes, while $|p\rangle_x, |s\rangle_x$ realize the independent Parasymmetry/Holosymmetry channels (cf. the Fourfold alphabet and words in Definition 4.141).

Remark 4.240 (Independence of p, s from twofold superpositions)**.** The equal-superposition vector $|+\rangle_x := \frac{1}{\sqrt{2}}\big(|0\rangle_x + |1\rangle_x\big)$ lives in the *twofold* sector and defines the local parasymmetric *effect* $P^{(x)}_{\mathrm{para}} = |+\rangle_x\langle+|$ (Hadamard/sum interferometer; see Corollary 4.168); it is not identified with the fourfold basis vector $|p\rangle_x$. Similarly, $|s\rangle_x$ is not assumed to be any linear combination of $|0\rangle_x, |1\rangle_x$. The p and s channels are independent fiber directions whose operational meanings are read via their dedicated effects (parasymmetric and holosymmetric, respectively) and the endogenous bracket/selection rules (Definition 4.203 and Corollary 4.205).

Local trivializations, gauge, and connection (formalization). On a coordinate patch $U \subset \mathcal{X}_q$, a smooth choice of ordered orthonormal frames $\{\mathcal{B}_x\}_{x\in U}$ trivializes the bundle as $\pi^{-1}(U) \cong U \times \mathbb{C}^4$. The *structure group* is the subgroup

$$G_{\mathrm{struct}} \subseteq U(4)$$

that preserves the $\{0, 1, p, s\}$ ordering (and, when invoked, the $\mathbb{Z}_2 \times \mathbb{Z}_2$ charge/grade; cf. Definition 4.201 and Corollary 4.205). Let $\{\mathcal{B}_x\}$ and $\{\widetilde{\mathcal{B}}_x\}$ be two trivializations on U with transition $g : U \to G_{\mathrm{struct}}$. Then the *bundle connection* is given in these frames by a $u(4)$-valued 1–form $\mathcal{A}$ transforming as

$$\widetilde{\mathcal{A}} \;=\; g\,\mathcal{A}\,g^{\dagger} \;+\; g\,\mathrm{d}g^{\dagger}, \qquad \mathcal{F} \;:=\; \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}, \tag{4.89}$$

and its parallel transport along an admissible path $\gamma : x' \to x$ is the path–ordered exponential

$$\mathcal{U}_{\mathcal{A}}(x \leftarrow x'; \gamma) \;:=\; \mathcal{P}\exp\Big(-\int_{\gamma}\mathcal{A}\Big), \tag{4.90}$$

which transforms by endpoint conjugation

$$\mathcal{U}_{\mathcal{A}} \mapsto g(x)\,\mathcal{U}_{\mathcal{A}}\,g(x')^{\dagger}$$

and coincides with the operational transporter of the theory:

$$\mathcal{U}_{\mathcal{A}}(x \leftarrow x';\gamma) \;=\; \mathcal{U}(x \leftarrow x';\gamma) \quad \text{from Definitions 4.48 and 4.49 and Section 4.19.1.} \tag{4.91}$$

In particular, $\mathcal{F}$ is the curvature controlling holonomy and the near–diagonal regularity of modal kernels (Theorem 4.230 and Proposition 4.213); on simply connected flat patches ($\mathcal{F} \equiv 0$) transport is path–independent (Proposition 4.59).

Proposition 4.241 (Metric compatibility and holonomy bound)**.** *Let K_x be the coincident–limit kernel defining the fiber inner product (eq. (4.85) and Proposition 4.233). Then for any admissible path $\gamma : x' \to x$,*

$$K_x \;=\; \mathcal{U}(x \leftarrow x';\gamma)\; K_{x'}\; \mathcal{U}(x \leftarrow x';\gamma)^{\dagger} \qquad \text{if } \; \mathcal{F}|_{\gamma} \equiv 0,$$

so that parallel transport gives unitary identifications of nearby fibers (metric compatibility). In general,

$$\Big\| K_x - \mathcal{U}(x \leftarrow x';\gamma)\; K_{x'}\; \mathcal{U}(x \leftarrow x';\gamma)^{\dagger} \Big\| \;\le\; C\,\Phi(\gamma),$$

where $\Phi(\gamma)$ is a holonomy functional controlled by $\mathcal{F}$ (non-Abelian Stokes–type estimate), as in Propositions 4.213 and 4.237.

Remark 4.242 (Compatibility with endogenous words and sectors)**.** The holosymmetric $\mathbb{Z}_2^2$ *charges* live in the device/dialectic factor and are preserved by G_{struct}, hence endogenous centrality, $0/s$ bosonic compatibility, and $p \leftrightarrow s$ nilpotency (Theorems 4.169, 4.170 and 4.173) apply fiberwise and glue across patches by (4.89)–(4.91). Sector decompositions by the spectral projectors of $\hat{G}^{ss}_{\Lambda}$ are bundle–compatible (Remark 4.211 and Proposition 4.188).

Fiberwise orthonormality (emergent). By construction from (4.85), each local frame is orthonormal:

$$\langle \alpha_x | \beta_x \rangle_{\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}} = \delta_{\alpha\beta}, \qquad \alpha,\beta \in \{0,1,p,s\}.$$

In particular, the twofold subbundle spanned by $\{|0\rangle_x, |1\rangle_x\}$ recovers the classical dyad, while mixing with $\{|p\rangle_x, |s\rangle_x\}$ is mediated by the off-diagonal channels of the Fourfold correlator.

We endow the fibers with a Hermitian (unitary) structure and fix the structure group $G \subseteq \mathrm{U}(4)$ acting in the fundamental representation. We assume *local triviality*: for every open set $U \subset \mathcal{X}_q$ there exists a unitary trivialization

$$\pi^{-1}(U) \;\cong\; U \times \mathbb{C}^4.$$

On overlaps $U \cap V$, the transition functions $g_{UV} : U \cap V \to G$ satisfy the cocycle conditions $g_{UU} = \mathbf{1}$, $g_{UV} = g_{VU}^{-1}$, and $g_{UV}\, g_{VW} = g_{UW}$. They relate frames by $|\alpha\rangle_V = g_{UV}^{-1}(x)\,|\alpha\rangle_U$ and therefore preserve the ordered modal frame $\{0,1,p,s\}$; when a grading is imposed, one may restrict to a grading–preserving subgroup, e.g. $G \subseteq \mathrm{U}(2) \times \mathrm{U}(2)$. The connection one–form $\mathcal{A} \in \Omega^1(\mathcal{X}_q, \mathfrak{g})$ with $\mathfrak{g} \subseteq \mathfrak{u}(4)$ and its parallel transporter $\mathcal{U}(x \leftarrow x';\gamma) = \mathcal{P}\exp\!\Big(-\int_{\gamma}\mathcal{A}\Big)$ (Section 4.1.4) provide the differential gluing data.

Definition 4.243 (Emergent modal frame and inner product)**.** At each locus $x \in \mathcal{X}_q$, let $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ be the modal fibre equipped with the emergent inner product constructed from the Fourfold correlator (Definitions 4.9 and 4.20 and eq. (4.6)). Equivalently, we may reference its coordinate form (4.85). Fix the ordered modal frame

$$\mathcal{B}_x := \Big\{ |0\rangle_x,\ |1\rangle_x,\ |p\rangle_x,\ |s\rangle_x \Big\}.$$

Proposition 4.244 (Fiberwise orthonormality)**.** *By construction from* (4.85) *(*or *Definition 4.20 and eq.* (4.6)*), each local frame $\mathcal{B}_x$ is orthonormal:*

$$\boxed{\langle \alpha_x \mid \beta_x \rangle_{\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}} = \delta_{\alpha\beta}, \qquad \alpha, \beta \in \{0, 1, p, s\}.} \tag{4.92}$$

Definition 4.245 (Twofold (classical) subbundle and para/holo complement)**.** Define the twofold subbundle $\mathcal{H}^{(0,1)} := \mathrm{span}\{|0\rangle_x, |1\rangle_x\}_{x \in \mathcal{X}_q}$ and its orthogonal complement $\mathcal{H}^{(p,s)} := \mathrm{span}\{|p\rangle_x, |s\rangle_x\}_{x \in \mathcal{X}_q}$.

Proposition 4.246 (Mixing controlled by off-diagonal Fourfold channels)**.** *Let $\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}_\Lambda^{\alpha\beta}(x, x')]_{\alpha,\beta \in \{0,1,p,s\}}$ be the Fourfold channel block matrix (Definition 4.81). Then, for any x, x',*

(i) If the off-diagonal blocks between the sectors vanish,

$$\hat{G}_\Lambda^{\alpha\beta}(x, x') = 0 \quad \text{for all } \alpha \in \{0, 1\},\ \beta \in \{p, s\} \text{ and for all } \alpha \in \{p, s\},\ \beta \in \{0, 1\},$$

the decomposition $\mathcal{H}^{(0,1)} \oplus \mathcal{H}^{(p,s)}$ is channel-invariant and no mixing occurs.

(ii) In general, for any unit vectors $u \in \mathcal{H}_{x'}^{(0,1)}$, $v \in \mathcal{H}_x^{(p,s)}$,

$$\Big| \langle v \mid \hat{\mathbf{G}}_\Lambda(x, x')\, u \rangle \Big| \ \le \sum_{\substack{\alpha \in \{p,s\} \\ \beta \in \{0,1\}}} \Big\| \hat{G}_\Lambda^{\alpha\beta}(x, x') \Big\|.$$

Thus the leakage amplitude from the classical dyad into the para/holo sector is bounded by the norms of the corresponding off-diagonal channel blocks.

Proof. (i) follows by block-diagonality of $\hat{\mathbf{G}}_\Lambda$. (ii) Expand the matrix element in the modal frames and apply Cauchy–Schwarz together with the operator norm bound. □

Definition 4.247 (Modal Hilbert bundle, structure group, and local triviality)**.** Let $\pi : \mathcal{E} \to \mathcal{X}_q$ be the Hermitian vector bundle with fibres $\mathcal{E}_x = \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$ and ordered frames $\mathcal{B}_x$. Fix the structure group $G \subseteq \mathrm{U}(4)$ acting in the fundamental representation and assume *local triviality*: for every open $U \subset \mathcal{X}_q$ there exists a unitary trivialization

$$\boxed{\pi^{-1}(U) \ \cong\ U \times \mathbb{C}^4.} \tag{4.93}$$

On overlaps $U \cap V$, the transition maps $g_{UV} : U \cap V \to G$ satisfy the cocycle conditions $g_{UU} = \mathbf{1}$, $g_{UV} = g_{VU}^{-1}$, and $g_{UV} g_{VW} = g_{UW}$, and relate frames by $|\alpha\rangle_V = g_{UV}^{-1}(x)\, |\alpha\rangle_U$ (preserving the order $\{0, 1, p, s\}$). When a grading is imposed, one may restrict to a grading–preserving subgroup, e.g. $G \subseteq \mathrm{U}(2) \times \mathrm{U}(2)$ (Section 4.1.7 and Definition 4.94).

Definition 4.248 (Connection and parallel transport (differential gluing data))**.** Let $\mathcal{A} \in \Omega^1(\mathcal{X}_q, \mathfrak{g})$ be a (skew–Hermitian) connection one–form with $\mathfrak{g} \subseteq \mathfrak{u}(4)$, and define the parallel transporter along a piecewise C^1 path γ by

$$\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{P} \exp\Big(-\int_\gamma \mathcal{A} \Big) \quad \text{(Definition 4.48 and eqs. (4.11) and (4.12)).}$$

Proposition 4.249 (Unitarity and inner-product preservation)**.** *For any path $\gamma : x' \to x$, the transporter $\mathcal{U}(x \leftarrow x'; \gamma) \in G \subseteq \mathrm{U}(4)$ is unitary and preserves the fibre inner products induced by (4.85): for all $\psi, \phi \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})}$,*

$$\big\langle \mathcal{U}\,\psi \;\big|\; \mathcal{U}\,\phi \big\rangle_{\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}} = \langle \psi \mid \phi \rangle_{\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})}}.$$

Proof. Skew–Hermiticity $\mathcal{A}^\dagger = -\mathcal{A}$ implies $\mathcal{U} \in \mathrm{U}(4)$ via the path-ordered exponential. Compatibility with the fibre metrics follows from the differential equation $\partial_s \mathcal{U} = -A_\gamma(s)\mathcal{U}$ and the standard argument that $\partial_s \langle \mathcal{U}\psi \mid \mathcal{U}\phi \rangle = 0$ (eq. (4.12) and Definition 4.49). □

Proposition 4.250 (Gauge covariance of frames, channels, and connection)**.** *Under $g : \mathcal{X}_q \to G$, $\mathcal{A} \mapsto g\mathcal{A}g^\dagger + (\mathrm{d}g)\, g^\dagger$ and $\mathcal{U}(x \leftarrow x'; \gamma) \mapsto g(x)\,\mathcal{U}(x \leftarrow x'; \gamma)\, g(x')^\dagger$ (Proposition 4.54). Frames transform by $|\alpha\rangle_x \mapsto g(x)\,|\alpha\rangle_x$, preserving (4.92). Fourfold channels obey endpoint covariance $\hat{G}_\Lambda^{\alpha\beta}(x, x') \mapsto g(x)\,\hat{G}_\Lambda^{\alpha\beta}(x, x')\, g(x')^\dagger$ (Corollary 4.64).*

Corollary 4.251 (Flatness and path–independence)**.** *If the curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A} \wedge \mathcal{A}$ vanishes on a simply connected open set (Definition 4.56), then $\mathcal{U}(x \leftarrow x'; \gamma)$ depends only on endpoints up to endpoint gauge (Proposition 4.59).*

Remark 4.252 (Classical dyad and emergent mixing)**.** The twofold subbundle $\mathcal{H}^{(0,1)}$ recovers the classical dyad at each fibre, and coupling to the (p, s) sector is exactly measured by the off-diagonal Fourfold channel blocks as in Proposition 4.246.

Remark 4.253 (Modal meaning of the fibers)**.** The fiber $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ over $x \in \mathcal{X}_q$ does not encode classical kinematics (e.g. position/momentum); rather, it carries the *internal modal content* of the PQS $\mathfrak{B}_x$ via the Fourfold Dialectic Algebra. After the inner product is fixed, choose an orthonormal frame

$$\mathcal{B}_x = \{|0\rangle_x,\ |1\rangle_x,\ |p\rangle_x,\ |s\rangle_x\},$$

realizing Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry as *independent* directions. In particular, $|p\rangle_x$ and $|s\rangle_x$ are not defined as linear combinations of $|0\rangle_x, |1\rangle_x$ (cf. Remark 4.240); the familiar equal-superposition $|+\rangle_x = \frac{1}{\sqrt{2}}(|0\rangle_x + |1\rangle_x)$ lives in the twofold sector and defines the *parasymmetric effect* $P_{\mathrm{para}}^{(x)} = |+\rangle_x\langle+|$, not the fourfold basis vector $|p\rangle_x$.

This internal, dialectical structure differs from permutation (anti)symmetry in many-body quantum mechanics [373]: it is an *intrinsic* attribute of a single pre-geometric quantum locus. The viewpoint aligns with algebraic QFT [230, 374], where internal state spaces are distinct from Fock-space constructions: the fibers supply kinematic labels and algebraic seeds from which the full dynamical symmetry content is generated.

Remark 4.254 (Categorical structure of the modal bundle)**.** The bundle admits a succinct categorical description as a presheaf of Hilbert spaces:

$$\mathscr{H} : \mathbf{Open}(\mathcal{X}_q)^{\mathrm{op}} \longrightarrow \mathbf{Hilb}, \qquad U \mapsto \Gamma(U, \mathscr{H}_{\mathrm{mod}}),$$

with inclusions $U \hookrightarrow V$ mapped to restriction morphisms $\Gamma(V, \mathscr{H}_{\mathrm{mod}}) \to \Gamma(U, \mathscr{H}_{\mathrm{mod}})$. This functorial viewpoint packages local trivializations, gauge transition data $\{g_{UV}\}$, and parallel transport as natural transformations, and it provides the natural setting to formulate sheaf/cohomological constraints on global sections and holonomy.

Conceptual takeaway. Interpreted functorially, the laws are the *coherence conditions* linking topology (covers and inclusions of $\mathcal{X}_q$) to quantum structure (sections and their restrictions). Parallel transport, connection, and curvature are the intrinsic consistency data of this map. Thus local modal amplitudes and global geometric structure are two faces of the same relational object: a globally coherent assignment $U \mapsto \Gamma(U, \mathscr{H}_{\mathrm{mod}})$ compatible with the Fourfold algebra, gauge covariance, and the graded selection rules.

4.6.2 Wordwise Modal Bundle, Frames, and Trivializations

Definition 4.255 (Word evaluation functor on channels)**.** Fix a device-level word $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ and a control transition $\chi_{\mathrm{in}} \to \chi_{\mathrm{out}}$. Let $\mathsf{W}_{\chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}}$ be the RR matrix element (Definition 4.148 and eq. (4.45)). For each pair (x, x') define the *word-evaluated* Fourfold channel matrix

$$\hat{\mathbf{G}}_\Lambda^{[\mathbf{W};\, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}]}(x, x') := \Big[\hat{G}_\Lambda^{\alpha\beta}(x, x'; \mathbf{W}, \chi_{\mathrm{out}} \leftarrow \chi_{\mathrm{in}}) \Big]_{\alpha,\beta \in \{0,1,p,s\}} \quad (\textit{Definition 4.166 and eq. (4.66)}). \tag{4.94}$$

This defines a functor $\mathcal{E}_{(\mathbf{W},\chi)} : \hat{\mathbf{G}}_\Lambda \mapsto \hat{\mathbf{G}}_\Lambda^{[\mathbf{W};\, \chi \leftarrow \chi]}$ on channel block-matrices.

Lemma 4.256 (Functoriality, gauge covariance, and unitarity)**.** *For admissible words* $\mathbf{W}_1, \mathbf{W}_2$, $\mathcal{E}_{(\mathbf{W}_2\mathbf{W}_1,\chi)} = \mathcal{E}_{(\mathbf{W}_2,\chi)} \circ \mathcal{E}_{(\mathbf{W}_1,\chi)}$. *Under endpoint gauge* $g : \mathcal{X}_q \to \mathrm{U}(\mathcal{H}_{\mathrm{em}})$,

$$\hat{\mathbf{G}}_\Lambda^{[\mathbf{W};\, \chi \leftarrow \chi]}(x, x') \mapsto g(x)\, \hat{\mathbf{G}}_\Lambda^{[\mathbf{W};\, \chi \leftarrow \chi]}(x, x')\, g(x')^\dagger \quad (\textit{Proposition 4.54 and Corollary 4.64}).$$

If $\mathbf{W}$ *is built from unitary elements (control gates and lifted RR histories), then* $\mathsf{W}_{\chi \leftarrow \chi}(x) \in \mathrm{U}(4)$ *acts unitarily on the fibre at* x.

Definition 4.257 (Wordwise modal frame)**.** Let $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ be the emergent orthonormal frame (Proposition 4.244). For a fixed $(\mathbf{W}, \chi)$, define the *wordwise rotated frame* at x by

$$|\alpha\rangle_x^{[\mathbf{W},\chi]} := \mathsf{W}_{\chi \leftarrow \chi}(x)\, |\alpha\rangle_x, \qquad \alpha \in \{0, 1, p, s\}.$$

Proposition 4.258 (Wordwise orthonormality and frame transport)**.** *If* $\mathbf{W}$ *is unitary on RR, then the frame* $\mathcal{B}_x^{[\mathbf{W},\chi]}$ *is orthonormal and*

$$\langle \alpha_x^{[\mathbf{W},\chi]} \mid \beta_x^{[\mathbf{W},\chi]} \rangle = \delta_{\alpha\beta} \quad (\textit{preserving eq. (4.92)}).$$

Along a path $\gamma : x' \to x$, transported frames relate by

$$|\alpha\rangle_x^{[\mathbf{W},\chi]} = \mathcal{U}(x \leftarrow x';\gamma)\,|\alpha\rangle_{x'}^{[\mathbf{W},\chi]} \quad \textit{for all } \alpha,$$

since $\mathsf{W}_{\chi\leftarrow\chi}$ acts by endpoint conjugation and $\mathcal{U}$ is unitary (Definition 4.248 and Proposition 4.249).

Definition 4.259 (Wordwise structure words and trivializations)**.** Fix $U \subset \mathcal{X}_q$. A *wordwise trivialization* on U is a choice of unitary word $\mathbf{W}_U$ and control χ such that the map

$$\Phi_U :\ \pi^{-1}(U) \to U \times \mathbb{C}^4, \qquad (x,\ v)\ \mapsto\ \Big(x,\ \mathsf{W}_{U,\chi\leftarrow\chi}(x)\,v\Big)$$

is a unitary fibre isomorphism. On overlaps $U \cap V$, set

$$g_{UV}^{[\mathrm{word}]}(x)\ :=\ \mathsf{W}_{U,\chi\leftarrow\chi}(x)\,\mathsf{W}_{V,\chi\leftarrow\chi}(x)^{\dagger} \in \mathrm{U}(4).$$

Proposition 4.260 (Wordwise transition cocycle and structure group)**.** *The wordwise transition maps satisfy $g_{UU}^{[\mathrm{word}]} = \mathbf{1}$, $g_{UV}^{[\mathrm{word}]} = (g_{VU}^{[\mathrm{word}]})^{-1}$, and $g_{UV}^{[\mathrm{word}]} g_{VW}^{[\mathrm{word}]} = g_{UW}^{[\mathrm{word}]}$ pointwise on triple overlaps. Hence the* wordwise structure group $G_{\mathrm{word}} \subseteq \mathrm{U}(4)$ *is realized as $\{\mathsf{W}_{\chi\leftarrow\chi}(x) :$ $\mathbf{W}$ unitary word$\}$, and the bundle is locally trivial via wordwise trivializations, compatible with eq. (4.93). If a grading is imposed, restrict to words whose RR elements preserve the $(0,1)\oplus(p,s)$ split, so $G_{\mathrm{word}} \subseteq \mathrm{U}(2)\times\mathrm{U}(2)$.*

Full proof. Let ℓ_ε be a smooth, contractible loop based at x, bounding an oriented disk Σ_ε of area $O(\varepsilon^2)$ and diameter $O(\varepsilon)$. By endpoint gauge covariance (Proposition 4.54), fix a local gauge on a neighbourhood $U \ni x$ with

$$\boxed{\mathcal{A}_\mu(x) = 0, \qquad \partial_\alpha \mathcal{A}_\mu(x)\ \text{ is bounded on } U.} \tag{4.95}$$

Write the loop holonomy $\mathcal{U}_{\ell_\varepsilon}(x) := \mathcal{P}\exp\Big(-\oint_{\ell_\varepsilon}\mathcal{A}\Big) \in \mathrm{U}(4)$ (Definition 4.56).

Step 1 (Small–loop expansion). Use the Dyson expansion of the path–ordered exponential together with Stokes:

$$\mathcal{U}_{\ell_\varepsilon}(x) = \mathbf{1}_4 - \int_{\Sigma_\varepsilon}\Big(\mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}\Big)(y)\ +\ R_\varepsilon = \mathbf{1}_4 - \int_{\Sigma_\varepsilon}\mathcal{F}(y)\ +\ R_\varepsilon,$$

with $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$ the curvature (Definition 4.56). In the gauge (4.95), $\mathcal{A}(y) = O(\varepsilon)$ on ℓ_ε; hence $\int_{\Sigma_\varepsilon}\mathcal{A}\wedge\mathcal{A} = O(\varepsilon^3)$ (area×diameter). Taylor expand $\mathcal{F}(y) = \mathcal{F}(x) + O(\varepsilon)$ on Σ_ε, and decompose the oriented area bivector as

$$\Sigma^{\mu\nu}(\ell_\varepsilon)\ :=\ \int_{\Sigma_\varepsilon} d\sigma^{\mu\nu}\ =\ \varepsilon^2\,\sigma^{\mu\nu}(\ell_\varepsilon), \qquad \sigma^{\mu\nu}(\ell_\varepsilon) = O(1).$$

Define the (area–normalised) linear functional

$$\boxed{\Phi_x(\mathcal{F})\ :=\ \sum_{\mu<\nu}\sigma^{\mu\nu}(\ell_\varepsilon)\,\mathcal{F}_{\mu\nu}(x),} \tag{4.96}$$

which is $O(1)$ and *independent* of ε at fixed loop shape. Then

$$\boxed{\begin{aligned}\mathcal{U}_{\ell_\varepsilon}(x) &= \mathbf{1}_4 - \int_{\Sigma_\varepsilon} \mathcal{F}(x) \;+\; O(\varepsilon^3) \\ &= \mathbf{1}_4 - \varepsilon^2\, \Phi_x(\mathcal{F}) \;+\; O(\varepsilon^3).\end{aligned}} \tag{4.97}$$

The commutator role of $\mathcal{F}$ is consistent with the curvature identity $[\mathbb{D}_\mu^{[\cdot]}, \mathbb{D}_\nu^{[\cdot]}]X = [\mathcal{F}_{\mu\nu}, X]$ (Proposition 4.224).

Step 2 (Insert into the wordwise s–loop operator). By eq. (4.122),

$$\hat{H}_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x) = \Big(\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^\dagger\, \mathcal{U}_{\ell_\varepsilon}(x)\, \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x).$$

Substitute (4.97):

$$\boxed{\hat{H}_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x) = \Big(\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^\dagger \Big(\mathbf{1}_4 - \varepsilon^2\, \Phi_x(\mathcal{F}) + O(\varepsilon^3)\Big) \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x).} \tag{4.98}$$

Gauge covariance of $\mathcal{U}$ and the endpoint fields (Propositions 4.54 and 4.294 and Corollary 4.64) implies $\hat{H}_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x)$ transforms by conjugation.

Step 3 (Expectation and invariance). Take the Holo–State expectation (eq. (4.123)):

$$\boxed{\begin{aligned} h_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x) &= \omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}_s^{[\cdot]})^\dagger \hat{\mathcal{F}}_s^{[\cdot]}\Big) \;-\; \varepsilon^2\, \omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}_s^{[\cdot]})^\dagger\, \Phi_x(\mathcal{F})\, \hat{\mathcal{F}}_s^{[\cdot]}\Big) \;+\; O(\varepsilon^3) \\ &=:\; h_{\mathrm{flat}}^{(s)[\mathbf{W}]}(x) \;-\; \varepsilon^2\, \omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}_s^{[\cdot]})^\dagger\, \Phi_x(\mathcal{F})\, \hat{\mathcal{F}}_s^{[\cdot]}\Big) \;+\; O(\varepsilon^3). \end{aligned}} \tag{4.99}$$

Since the scalar expectation is invariant under endpoint gauge and word changes act by fibrewise unitary conjugation (Propositions 4.284 and 4.294), $h_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x)$ is gauge invariant. In the flat, simply connected case $\mathcal{F} \equiv 0$ one recovers $h_{\ell_\varepsilon}^{(s)[\mathbf{W}]}(x) = h_{\mathrm{flat}}^{(s)[\mathbf{W}]}(x)$ (Proposition 4.295).

Step 4 (Remainder bound). Let $M_1 = \sup_U \|\partial\mathcal{A}\|$ and $M_2 = \sup_U \big(\|\mathcal{A}\|^2 + \|\partial\mathcal{F}\|\big)$. Then the Dyson remainder satisfies $\|R_\varepsilon\| \le C\,(\text{area}) \times (\text{diameter}) \le C'(M_1, M_2)\,\varepsilon^3$, justifying the $O(\varepsilon^3)$ terms in (4.97)–(4.99). This completes the proof. □

4.6.3 Wordwise Channels, Mixing Bounds, and Kinematics

Definition 4.261 (Wordwise twofold/para–holo split)**.** Define the word-rotated subspaces at x

$$\mathcal{H}_x^{(0,1)[\mathbf{W}]} := \mathrm{span}\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\}, \qquad \mathcal{H}_x^{(p,s)[\mathbf{W}]} := \mathrm{span}\{|p\rangle_x^{[\mathbf{W},\chi]}, |s\rangle_x^{[\mathbf{W},\chi]}\}.$$

Proposition 4.262 (Wordwise mixing controlled by off-diagonal blocks)**.** *Let* $\hat{\mathbf{G}}_\Lambda^{[\mathbf{W}]}(x,x')$ *denote the word-evaluated channel matrix (Definition 4.255). Then, for unit vectors* $u \in \mathcal{H}_{x'}^{(0,1)[\mathbf{W}]}$, $v \in \mathcal{H}_x^{(p,s)[\mathbf{W}]}$,

$$\Big|\langle v \mid \hat{\mathbf{G}}_\Lambda^{[\mathbf{W}]}(x,x')\, u\rangle\Big| \;\le\; \sum_{\substack{\alpha\in\{p,s\}\\ \beta\in\{0,1\}}} \Big\|\hat{G}_\Lambda^{\alpha\beta}(x,x';\mathbf{W},\chi\leftarrow\chi)\Big\|.$$

In particular, if all such off-diagonal blocks vanish, the split $\mathcal{H}^{(0,1)[\mathbf{W}]} \oplus \mathcal{H}^{(p,s)[\mathbf{W}]}$ is invariant and no mixing occurs.

Proof. Expand in the word-rotated frames and apply Cauchy–Schwarz and operator norm bounds, as in Proposition 4.246. □

Definition 4.263 (Wordwise covariant derivative and curvature)**.** Using the connection $\mathcal{A}$ on the base (Definition 4.248), define for each word-evaluated component the derivative

$$\mathbb{D}_\mu^{[\mathbf{W}]} \hat{G}^{\alpha\beta} := \partial_\mu \hat{G}^{\alpha\beta} + [\,\mathcal{A}_\mu, \hat{G}^{\alpha\beta}\,],$$

and along a path γ the path-derivative $\partial_s + [A_\gamma(s), \cdot\,]$ with $A_\gamma = (\gamma^*\mathcal{A})(\dot\gamma)$ (Section 4.5, Definition 4.220, and Proposition 4.223). The curvature is $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A} \wedge \mathcal{A}$ (Definition 4.56).

Proposition 4.264 (Wordwise curvature identity and flatness)**.** *For any word-evaluated channel X, $[\mathbb{D}_\mu^{[\mathbf{W}]}, \mathbb{D}_\nu^{[\mathbf{W}]}]X = [\mathcal{F}_{\mu\nu}, X]$ (Proposition 4.224). If $\mathcal{F} = 0$ on a simply connected region, parallel consistency integrates to word–path independence up to endpoint gauge (Propositions 4.59 and 4.223).*

Remark 4.265 (Dictionary back to the exogenous bundle)**.** The endogenous objects above reproduce the exogenous formalization via:

1. frames $\mathcal{B}_x^{[\mathbf{W},\chi]} \leftrightarrow$ frames $\mathcal{B}_x$ acted on by $G \subseteq \mathrm{U}(4)$ (Definitions 4.247 and 4.257 and Proposition 4.258);
2. transition words $g_{UV}^{[\mathrm{word}]} \leftrightarrow$ transition functions g_{UV} (Definition 4.259 and Proposition 4.260);
3. word-evaluated channels $\hat{\mathbf{G}}_\Lambda^{[\mathbf{W}]} \leftrightarrow$ channel blocks $\hat{\mathbf{G}}_\Lambda$ (Definition 4.255);
4. wordwise kinematics $\mathbb{D}_\mu^{[\mathbf{W}]}, \partial_s + [A_\gamma, \cdot\,] \leftrightarrow$ graded/exogenous kinematics $\mathfrak{D}_\mu, D_s$ (Section 4.5, Definition 4.134, and Proposition 4.137);
5. mixing bound Proposition 4.262 $\leftrightarrow$ Proposition 4.246.

4.6.4 Global Section of Dialectic Modes

Definition 4.266 (Global section of dialectic modes)**.** Let $(\mathscr{H}_{\mathrm{mod}}, \pi, \mathcal{X}_q)$ be the Hilbert bundle of dialectic modes from Definition 4.239. A *global section* is a smooth map

$$\boxed{|\Psi_{\mathrm{modal}}\rangle : \ \mathcal{X}_q \longrightarrow \mathscr{H}_{\mathrm{mod}}, \qquad x \ \longmapsto \ |\Psi_{\mathrm{modal}}(x)\rangle \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)},} \tag{4.100}$$

satisfying the section condition $\pi \circ |\Psi_{\mathrm{modal}}\rangle = \mathrm{id}_{\mathcal{X}_q}$. On any trivializing patch $U \subset \mathcal{X}_q$ with orthonormal frame $\mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ (cf. eq. (4.92)), the section has the local expansion

$$|\Psi_{\mathrm{modal}}(x)\rangle = \sum_{\alpha \in \{0,1,p,s\}} c_\alpha(x)\, |\alpha\rangle_x \quad (x \in U), \tag{4.101}$$

with smooth coefficients $c_\alpha : U \to \mathbb{C}$ collected as $c(x) := (c_0, c_1, c_p, c_s)^\top$. Pointwise normalization in each fiber is

$$\boxed{c(x)^\dagger c(x) = |c_0(x)|^2 + |c_1(x)|^2 + |c_p(x)|^2 + |c_s(x)|^2 = 1 \qquad (\forall x \in U).} \tag{4.102}$$

On an overlap $U\cap V$, coefficient vectors are related by the transition matrix $g_{UV}(x) \in G \subseteq U(4)$ (preserving the ordered mode frame and, when invoked, the $\mathbb{Z}_2 \times \mathbb{Z}_2$ grading):

$$\boxed{c_U(x) \;=\; g_{UV}(x)\, c_V(x), \qquad x \in U \cap V,} \tag{4.103}$$

so (4.102) is gauge invariant.

Remark 4.267 (Gauge–Covariant Differentiation and Transport of a Section)**.** Let $\mathcal{A}$ be the connection one–form introduced in Section 4.1.4, with transporter $\mathcal{U} = \mathcal{P}\exp(-\int \mathcal{A})$. The *covariant derivative* of a section is

$$\boxed{\mathfrak{D}_\mu|\Psi_{\text{modal}}(x)\rangle := \partial_\mu|\Psi_{\text{modal}}(x)\rangle + \mathcal{A}_\mu(x)\,|\Psi_{\text{modal}}(x)\rangle,} \tag{4.104}$$

which transforms homogeneously under $g(x) \in G$ and preserves the pointwise norm $c(x)^\dagger c(x)$. Parallel sections obey $\mathfrak{D}_\mu|\Psi_{\text{modal}}\rangle = 0$, and holonomy is generated by the curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$.

Remark 4.268 (Fiberwise Expectations and Density)**.** The fiberwise density operator of a section is $\rho_{\text{modal}}(x) := |\Psi_{\text{modal}}(x)\rangle\langle\Psi_{\text{modal}}(x)|$. For any fiber observable $\hat{O}(x)$ (e.g. mode projectors), the local expectation $\langle\hat{O}\rangle(x) := \mathrm{Tr}\big(\rho_{\text{modal}}(x)\hat{O}(x)\big)$ is gauge invariant. Coupling to inter–locus physics proceeds via the Fourfold correlator and the transporter (cf. Sections 4.1.2 and 4.1.4).

Remark 4.269 (Independence of p, s from Twofold Superpositions)**.** The coefficients $c_p(x)$ and $c_s(x)$ weight *independent* fiber directions $|p\rangle_x$ and $|s\rangle_x$. They are not fixed by twofold superpositions (see Remark 4.240); in particular $|+\rangle_x = \frac{1}{\sqrt{2}}(|0\rangle_x + |1\rangle_x)$ defines a twofold *effect*, not the fourfold basis vector $|p\rangle_x$.

Lemma 4.270 (Fiberwise Pairing is Well Defined, Gauge Invariant, and Covariantly Leibniz)**.** *Let $|\Phi_{\text{modal}}\rangle, |\Psi_{\text{modal}}\rangle$ be global sections of $(\mathscr{H}_{\text{mod}}, \pi, \mathcal{X}_q)$, and let $\langle\cdot,\cdot\rangle_x$ denote the inner product on the fiber $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$. Choose a local trivialization (U, e_U) with orthonormal frame $e_U(x) = (|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x)$, and write $|\Phi_{\text{modal}}(x)\rangle = e_U(x)c_U^\Phi(x)$, $|\Psi_{\text{modal}}(x)\rangle = e_U(x)c_U^\Psi(x)$ with column maps $c_U^\Phi, c_U^\Psi : U \to \mathbb{C}^4$.*

Then, for each $x \in \mathcal{X}_q$:

1. Well defined and gauge invariant. *On overlaps $U\cap V$, let $e_V(x) = e_U(x)\, g_{UV}(x)$ with $g_{UV} : U\cap V \to G \subseteq U(4)$. Then $c_V^\Phi = g_{UV}^{-1}c_U^\Phi$, $c_V^\Psi = g_{UV}^{-1}c_U^\Psi$ and*

$$\langle\Phi_{\text{modal}}(x), \Psi_{\text{modal}}(x)\rangle_x = (c_U^\Phi(x))^\dagger c_U^\Psi(x) = (c_V^\Phi(x))^\dagger c_V^\Psi(x),$$

so the scalar function $x \mapsto \langle\Phi_{\text{modal}}(x), \Psi_{\text{modal}}(x)\rangle_x$ is independent of trivialization and invariant under G–gauge frame changes.

2. Covariant Leibniz rule (metric compatibility). *Let $\mathcal{A}_\mu$ be the connection one–form of Section 4.1.4 and $\mathfrak{D}_\mu$ the covariant derivative of eq. (4.104), with $\mathcal{A}_\mu^\dagger = -\mathcal{A}_\mu$ (skew–Hermitian). Then, for all μ,*

$$\boxed{\begin{aligned}\partial_\mu\,\langle\Phi_{\text{modal}}(x), \Psi_{\text{modal}}(x)\rangle_x = &\Big\langle \mathfrak{D}_\mu\Phi_{\text{modal}}(x),\, \Psi_{\text{modal}}(x)\Big\rangle_x \\ &+ \Big\langle \Phi_{\text{modal}}(x),\, \mathfrak{D}_\mu\Psi_{\text{modal}}(x)\Big\rangle_x.\end{aligned}} \tag{4.105}$$

In particular, along any curve $\gamma : \lambda \mapsto x(\lambda)$, if $\mathfrak{D}_{\dot\gamma}|\Psi_{\text{modal}}\rangle = 0$ (parallel transport), then $\frac{d}{d\lambda}\langle\Psi_{\text{modal}}, \Psi_{\text{modal}}\rangle = 0$: norms and orthonormality are preserved by parallel transport.

Proof. Fix a trivialising patch $U \subset \mathcal{X}_q$ with an orthonormal modal frame at $x \in U$,

$$e_U(x) \coloneqq \Big(|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\Big).$$

Write the coefficient column vectors $c_U^\Phi(x), c_U^\Psi(x) \in \mathbb{C}^4$, and set

$$|\Phi_{\text{modal}}(x)\rangle = e_U(x)\, c_U^\Phi(x), \qquad |\Psi_{\text{modal}}(x)\rangle = e_U(x)\, c_U^\Psi(x).$$

With the fibre inner product $\langle\cdot,\cdot\rangle_x$ (induced as in Definition 4.228) and the orthonormality of $e_U(x)$, we obtain

$$\Big\langle \Phi_{\text{modal}}(x), \Psi_{\text{modal}}(x)\Big\rangle_x = \Big(c_U^\Phi(x)\Big)^\dagger c_U^\Psi(x).$$

On an overlap $U \cap V \neq \varnothing$ let $e_V(x) = e_U(x)\, g_{UV}(x)$ with $g_{UV}(x) \in G \subseteq U(4)$. Then coefficients transform as $c_V^\Phi(x) = g_{UV}(x)^{-1} c_U^\Phi(x)$ and $c_V^\Psi(x) = g_{UV}(x)^{-1} c_U^\Psi(x)$, hence

$$(c_V^\Phi(x))^\dagger c_V^\Psi(x) = (c_U^\Phi(x))^\dagger\, (g_{UV}^{-1}(x))^\dagger g_{UV}^{-1}(x)\, c_U^\Psi(x) = (c_U^\Phi(x))^\dagger c_U^\Psi(x),$$

proving the gauge/trivialization invariance in (1). Equivalently, a local frame change $g(x) \in G$ acting by $|\Phi\rangle \mapsto g|\Phi\rangle$, $|\Psi\rangle \mapsto g|\Psi\rangle$ preserves the fiber pairing since $g^\dagger g = \mathbf{1}$.

For (2), use the covariant derivative $\mathfrak{D}_\mu = \partial_\mu + \mathcal{A}_\mu$ with $\mathcal{A}_\mu^\dagger = -\mathcal{A}_\mu$. In a local frame,

$$\partial_\mu\Big[(c_U^\Phi(x))^\dagger c_U^\Psi(x)\Big] = (\mathfrak{D}_\mu c_U^\Phi(x))^\dagger c_U^\Psi(x) + (c_U^\Phi(x))^\dagger (\mathfrak{D}_\mu c_U^\Psi(x)),$$

because the cross terms cancel: $(c_U^\Phi)^\dagger \mathcal{A}_\mu c_U^\Psi + (\mathcal{A}_\mu c_U^\Phi)^\dagger c_U^\Psi = (c_U^\Phi)^\dagger(\mathcal{A}_\mu + \mathcal{A}_\mu^\dagger) c_U^\Psi = 0$. Translating back to fiber pairings gives (4.105). Taking $\Phi = \Psi$ and restricting to a curve γ with $\mathfrak{D}_{\dot\gamma}|\Psi_{\text{modal}}\rangle = 0$ yields $\frac{d}{d\lambda}\langle\Psi_{\text{modal}}, \Psi_{\text{modal}}\rangle = 0$; norms and orthonormality are preserved by parallel transport. □

Remark 4.271 (Unitary Frames and h-Orthonormal Generalisation)**.** (i) In an orthonormal trivialisation (fibre metric $h = \mathbb{1}_4$), it is convenient to write the identity as $\mathbb{1}_4$ to emphasise rank, so for any frame change $g \in U(4)$ one has $g^\dagger g = \mathbb{1}_4$.

(ii) In a non-orthonormal trivialisation with fibre metric $h(x)$ (a smooth, positive-definite Hermitian form), the structure group reduces to

$$G_h \coloneqq \{\, g \in \mathrm{GL}(4,\mathbb{C}) \mid g^\dagger h\, g = h \,\}.$$

Frames transform as $e_V = e_U g$ and coefficients as $c_V = g^{-1} c_U$, and the fibre pairing is

$$\langle \Phi_{\text{modal}}, \Psi_{\text{modal}}\rangle_x = (c_U^\Phi)^\dagger h\, c_U^\Psi = (c_V^\Phi)^\dagger h\, c_V^\Psi,$$

since $(g^{-1})^\dagger h\, g^{-1} = h$ follows from $g^\dagger h g = h$. If the connection $\mathcal{A}_\mu$ is metric–compatible,

$$\partial_\mu h \;-\; \mathcal{A}_\mu^\dagger h \;-\; h\,\mathcal{A}_\mu \;=\; 0,$$

then with $\mathfrak{D}_\mu = \partial_\mu + \mathcal{A}_\mu$ one has the covariant Leibniz rule

$$\partial_\mu\Big[(c_U^\Phi)^\dagger h\, c_U^\Psi\Big] = (\mathfrak{D}_\mu c_U^\Phi)^\dagger h\, c_U^\Psi + (c_U^\Phi)^\dagger h\, (\mathfrak{D}_\mu c_U^\Psi), \tag{4.106}$$

which reduces to eq. (4.105) when $h = \mathbb{1}_4$.

Corollary 4.272 (Gauge Invariance and Parallel Constancy of Mode Weights)**.** *Let* $P_\alpha(x) = |\alpha\rangle_x\langle\alpha|_x$ *be the rank-one projectors onto the modal basis* $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$*. For any global section* $|\Psi_{\text{modal}}\rangle$ *define* $w_\alpha(x) := \langle\Psi_{\text{modal}}(x),\, P_\alpha(x)\,\Psi_{\text{modal}}(x)\rangle_x = |c_\alpha(x)|^2$*. Then:*

(1) $w_\alpha(x)$ *is independent of the choice of trivialization and invariant under local* G*–frame changes on overlaps.*

(2) *Along a curve* γ*, if the state is parallel transported* $\mathfrak{D}_{\dot\gamma}|\Psi_{\text{modal}}\rangle = 0$ and *the projectors are propagated by the same connection (i.e.* $\mathfrak{D}_{\dot\gamma}P_\alpha = 0$*, equivalently the modal frame is chosen covariantly constant along* γ*), then* $\frac{d}{d\lambda}\, w_\alpha(\gamma(\lambda)) = 0$*.*

Physically, a global section $|\Psi_{\text{modal}}(x)\rangle$ is the spatially varying **dialectical profile** of a quantum field over $\mathcal{X}_q$. By specifying the local amplitudes of all four modes at each locus, it can encode either an emergent vacuum configuration or a particle-like excitation. Mathematically, this mirrors the way sections of spinor bundles represent fermion fields and sections of gauge bundles encode gauge potentials in geometric field theory [375, 225].

Global sections as dialectic quantum fields. Unlike the conventional view in which a composite quantum system lives in a fixed tensor power $\mathcal{H}_2^{\otimes n}$, the present framework is intrinsically geometric and operator-algebraic [4, 241]. A system of n distinguishable entities is modeled by n Primordial Quantum Singularities (PQSs) $\mathfrak{B}_{x_1}, \ldots, \mathfrak{B}_{x_n}$ located at points $x_i \in \mathcal{X}_q$, each equipped with its own *modal Hilbert fiber* $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_{x_i})}$ whose inner product is *emergent* and state-dependent [11]. In this setting, a quantum field is a *global section* of the Hilbert bundle of dialectic modes: a smooth assignment

$$x \longmapsto |\Psi_{\text{modal}}(x)\rangle \in \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)},$$

selecting at each point a superposition of the four dialectical modes.

At any $x \in \mathcal{X}_q$, the local modal state has the form

$$|\Psi_{\text{modal}}(x)\rangle = c_0(x)\,|\mathring{\mathbf{0}}\rangle_x + c_1(x)\,|\mathring{\mathbf{1}}\rangle_x + c_p(x)\,|\mathring{\mathbf{0}} + \mathring{\mathbf{1}}\rangle_x + c_s(x)\,\big|_{\mathring{\mathbf{0}}}\mathring{\Lambda}_{\mathring{\mathbf{1}}}\big\rangle_x,$$

where the orthonormal basis encodes the Fourfold Dialectic Algebra (Symmetry/Thesis, Antisymmetry/Antithesis, Parasymmetry/Synthesis, Holosymmetry/Holothesis), and the coefficients $c_\alpha(x) \in \mathbb{C}$ satisfy the pointwise normalization

$$|c_0(x)|^2 + |c_1(x)|^2 + |c_p(x)|^2 + |c_s(x)|^2 = 1.$$

The map $x \mapsto (c_0, c_1, c_p, c_s)(x)$ determines the field's "shape" across $\mathcal{X}_q$, from uniform dialectical vacua to localized excitations propagating on the quantum-relational substrate.

This generalizes familiar constructions in modern field theory: just as spinor and gauge fields are sections of their respective bundles [225, 375], a global section of the modal Hilbert bundle furnishes a fundamental field of the IQR. It simultaneously captures locality (one fiber per PQS) and the global logic of duality that organizes their modal evolution. Gauge-covariant comparison between fibers is mediated by the parallel transporter, and fiberwise pairings are well defined, gauge invariant, and preserved by parallel transport (cf. Lemma 4.270). In this way, the total fibered space (see Definition 4.239) becomes the stage on which the dialectical dynamics of the quantum universe unfold, with the global section providing the field that inhabits it.

Definition 4.273 (Modal Hilbert Space of a Primordial Quantum Singularity)**.** Fix a locus $x \in \mathcal{X}_q$ with associated Primordial Quantum Singularity $\mathfrak{B}_x$ (Definition 1.25). Its intrinsic operator-theoretic duality

$$\hat{\mathbf{\Omega}}_x = \overset{\circ}{\underset{\hat{\mathbf{\Phi}}_x}{\mathbf{\Lambda}}}_{x,\hat{\mathbf{\Theta}}_x}$$

encodes the Fourfold Dialectic Algebra (modes: Symmetry, Antisymmetry, Parasymmetry, Holosymmetry). The *modal Hilbert space* at x is the emergent fiber

$$\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4,$$

whose inner product is defined relationally by the Fourfold Inter-Modal Correlator in the Holo-State (cf. Section 4.6, (4.85)).

Realization map and orthonormal basis. Let $\mathcal{I} := \{0, 1, p, s\}$ be the mode labels and $\mathcal{R}_x : \mathcal{I} \to \mathbb{P}\big(\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}\big)$ the realization map sending a label to a ray. After the inner product is fixed, choose unit representatives

$$\mathcal{B}_x := \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}, \qquad \mathcal{R}_x(\alpha) = [\,|\alpha\rangle_x\,],$$

and impose the *ontological orthonormality*

$$\boxed{\langle \alpha_x \mid \beta_x \rangle \;=\; \delta_{\alpha\beta}, \qquad \alpha, \beta \in \{0, 1, p, s\}.} \tag{4.107}$$

Caution: $|p\rangle_x$ and $|s\rangle_x$ are independent basis vectors. The equal-superposition $|+\rangle_x := \frac{1}{\sqrt{2}}(|0\rangle_x + |1\rangle_x)$ belongs to the Twofold sector and defines the local parasymmetric *effect* $P_{\text{para}}^{(x)} = |+\rangle_x\langle+|$; it is not identified with $|p\rangle_x$.

Modal decomposition. With the shorthand $\mathcal{H}_{\alpha,x} := \text{span}\{|\,\alpha\rangle_x\}$ one has the direct sum

$$\boxed{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} = \mathcal{H}_{0,x} \oplus \mathcal{H}_{1,x} \oplus \mathcal{H}_{p,x} \oplus \mathcal{H}_{s,x}.} \tag{4.108}$$

State representation. Every $|\psi\rangle_x \in \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ admits the expansion

$$|\psi\rangle_x = c_0(x)\,|0\rangle_x + c_1(x)\,|1\rangle_x + c_p(x)\,|p\rangle_x + c_s(x)\,|s\rangle_x,$$

with pointwise normalization

$$|c_0(x)|^2 + |c_1(x)|^2 + |c_p(x)|^2 + |c_s(x)|^2 = 1.$$

Interpretation. The fiber $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ is a locally constructed, relationally defined quantum space that carries the irreducible dialectic content at x. It is not a fixed tensor factor but the arena where the four modal facets are represented and compared; its metric is induced by the correlator expectations, ensuring full consistency with gauge-covariant transport and the Fourfold algebraic structure.

Remark 4.274 (On the Interpretation of Dialectic Modes)**.** At each locus $x \in \mathcal{X}_q$, the modal fiber $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ carries an orthonormal basis $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ (cf. (4.92)), representing the four canonical facets of the Fourfold Dialectic Algebra: *Symmetry* (Thesis), *Antisymmetry* (Antithesis), *Parasymmetry* (Synthesis), and *Holosymmetry* (Holothesis). These modes are determined by the internal duality operator $\mathring{\mathbf{\Lambda}}_x$ as it appears inside the fibred operator-theoretic structure $\hat{\mathbf{\Omega}}_x = {}_{\hat{\Phi}_x}\mathring{\mathbf{\Lambda}}_{x,\hat{\Theta}_x}$, and are intrinsic to the singularity $\mathfrak{B}_x$.

It is essential to distinguish this notion of "(anti)symmetry" from the standard permutation-(anti)symmetry under S_n in many-body quantum mechanics, where symmetric/antisymmetric subspaces encode particle-exchange statistics on tensor products [376, 373]. Here, by contrast, the modal basis is a *local, internal* dialectic of a single Primordial Quantum Singularity; it is not obtained by (anti)symmetrizing over identical constituents. This viewpoint aligns with algebraic/categorical treatments in modern quantum theory [230, 377, 374], where internal state spaces are organized fiberwise over configuration spaces and possess their own intrinsic logic and geometry.

A further clarification is crucial for the higher modes. The parasymmetric basis vector $|p\rangle_x$ is *not* defined as the equal-superposition vector $|+\rangle_x := \frac{1}{\sqrt{2}}(|0\rangle_x + |1\rangle_x)$; the latter belongs to the Twofold sector and underlies the local parasymmetric *effect* $P^{(x)}_{\mathrm{para}} = |+\rangle_x\langle+|$, whereas $|p\rangle_x$ is an independent basis ray for the Fourfold algebra. Likewise, $|s\rangle_x$ (holosymmetry) is not assumed to be a linear combination of $|0\rangle_x$ and $|1\rangle_x$; operationally it is accessed via holosymmetric effects that probe implementation-invariant, history-level structure.

In this way the Fourfold Dialectic Algebra supplies more than a convenient labeling scheme: it furnishes a local, ontological basis from which internal geometry, logical duality, and coherence properties are read. Parasymmetric channels register coherence-sensitive synthesis beyond mixtures, while holosymmetric channels register global, implementation-invariant constraints— all within the same fiberwise, operator-algebraic framework.

4.6.5 Wordwise Global Section of Dialectic Modes

Definition 4.275 (Wordwise global section of dialectic modes)**.** Fix a unitary device word $\mathbf{W} \in \langle \mathsf{A}_{\mathrm{holo}} \rangle$ and a control label χ. Let $\mathsf{W}_{\chi\leftarrow\chi}(x)$ be its RR element at x (Definition 4.148 and eq. (4.45)). A *wordwise global section* is a smooth map

$$|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}\rangle : \ \mathcal{X}_q \to \mathscr{H}_{\mathrm{mod}}, \qquad x \mapsto |\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle \in \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}},$$

that admits on each trivialising patch $U \subset \mathcal{X}_q$ the expansion in the *wordwise frame* $\mathcal{B}^{[\mathbf{W},\chi]}_x = \{|0\rangle^{[\mathbf{W},\chi]}_x, |1\rangle^{[\mathbf{W},\chi]}_x, |p\rangle^{[\mathbf{W},\chi]}_x, |s\rangle^{[\mathbf{W},\chi]}_x\}$ (Definition 4.257):

$$|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle = \sum_{\alpha\in\{0,1,p,s\}} c^{[\mathbf{W}]}_\alpha(x)\, |\alpha\rangle^{[\mathbf{W},\chi]}_x \quad (x \in U), \tag{4.109}$$

with smooth coefficients $c^{[\mathbf{W}]}_\alpha : U \to \mathbb{C}$.

Proposition 4.276 (Normalization and gauge invariance)**.** *If* $\mathbf{W}$ *is unitary on RR, the wordwise frame is orthonormal (Proposition 4.258), and the coefficient vector* $c^{[\mathbf{W}]}(x) :=$

$(c_0^{[\mathbf{W}]}, c_1^{[\mathbf{W}]}, c_p^{[\mathbf{W}]}, c_s^{[\mathbf{W}]})^\top$ *satisfies the pointwise normalization*

$$\boxed{(c^{[\mathbf{W}]}(x))^\dagger c^{[\mathbf{W}]}(x) = 1 \qquad (\forall x \in U).} \tag{4.110}$$

Under endpoint gauge $g : \mathcal{X}_q \to \mathrm{U}(4)$, $|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle \mapsto g(x)\,|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle$ *and* (4.110) *is invariant.*

Proof. Let $\{|\phi_\mu(x)\rangle\}_{\mu\in\{0,1,p,s\}}$ be the wordwise modal frame at x, which is orthonormal by Proposition 4.258. Write the dressed modal state in this frame as

$$|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle = \sum_{\mu\in\{0,1,p,s\}} c_\mu^{[\mathbf{W}]}(x)\,|\phi_\mu(x)\rangle, \qquad c^{[\mathbf{W}]}(x) = \left(c_0^{[\mathbf{W}]}, c_1^{[\mathbf{W}]}, c_p^{[\mathbf{W}]}, c_s^{[\mathbf{W}]}\right)^\top.$$

Normalization. Since the frame is orthonormal,

$$\left\| \, |\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle \, \right\|^2 = \sum_\mu \left| c_\mu^{[\mathbf{W}]}(x) \right|^2 = \left(c^{[\mathbf{W}]}(x)\right)^\dagger c^{[\mathbf{W}]}(x).$$

It therefore suffices to show $\| \, |\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle\| = 1$. By the wordwise dressing rule (cf. eq. (4.67)) the state is obtained by applying, to a unit-norm input, the product of three factors: (i) the parallel transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ on the base, (ii) the RR–matrix element $\mathsf{W}_{\chi_{\mathrm{out}}\leftarrow\chi_{\mathrm{in}}}$ of $\mathbf{W}$ (cf. Definition 4.148 and eq. (4.45)), and (iii) the orthonormal frame map at x/x'. By assumption, $\mathbf{W}$ is unitary on RR, hence $\mathsf{W}_{\chi\leftarrow\chi}$ is unitary (on $\mathcal{H}^{(2n)}_{\mathrm{RR}}$); $\mathcal{U}$ is unitary by construction; and the frame maps are isometries due to orthonormality. Consequently the composite map is norm-preserving, so $\| \, |\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle\| = 1$ and hence

$$\left(c^{[\mathbf{W}]}(x)\right)^\dagger c^{[\mathbf{W}]}(x) = 1,$$

which is eq. (4.110).

Gauge invariance. Under an endpoint gauge $g : \mathcal{X}_q \to \mathrm{U}(4)$ on the modal fibre, the state transforms as $|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle \mapsto g(x)\,|\Psi^{[\mathbf{W},\chi]}_{\mathrm{modal}}(x)\rangle$ (cf. gauge covariance in Proposition 4.167(a)). With the column of coefficients $c^{[\mathbf{W}]}(x)$ taken in the *local* frame at x, this is equivalently $c^{[\mathbf{W}]}(x) \mapsto g(x)\,c^{[\mathbf{W}]}(x)$. Since $g(x) \in \mathrm{U}(4)$,

$$\left(c^{[\mathbf{W}]}(x)\right)^\dagger c^{[\mathbf{W}]}(x) \;\longmapsto\; \left(c^{[\mathbf{W}]}(x)\right)^\dagger g(x)^\dagger g(x)\, c^{[\mathbf{W}]}(x) = \left(c^{[\mathbf{W}]}(x)\right)^\dagger c^{[\mathbf{W}]}(x),$$

so eq. (4.110) is gauge invariant pointwise on U.

This establishes Proposition 4.276. □

Definition 4.277 (Wordwise transitions on overlaps)**.** Let $U, V \subset \mathcal{X}_q$ be trivialising patches with wordwise trivializations $\mathbf{W}_U, \mathbf{W}_V$ (Definition 4.259). On $U \cap V$, define the transition word $g^{[\mathrm{word}]}_{UV}(x) = \mathsf{W}_{U,\chi\leftarrow\chi}(x)\,\mathsf{W}_{V,\chi\leftarrow\chi}(x)^\dagger \in \mathrm{U}(4)$ (Proposition 4.260). Then the coefficient vectors obey

$$\boxed{c_U^{[\mathbf{W}]}(x) = g^{[\mathrm{word}]}_{UV}(x)\, c_V^{[\mathbf{W}]}(x) \qquad (x \in U \cap V),} \tag{4.111}$$

so that (4.110) is patchwise consistent.

Remark 4.278 (Wordwise covariant derivative of a section)**.** With the base connection $\mathcal{A}$ (Definition 4.248), define the *wordwise covariant derivative* of the section by

$$\boxed{\mathbb{D}_\mu^{[\mathbf{W}]}|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle := \partial_\mu|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle + \mathcal{A}_\mu(x)\,|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle.} \tag{4.112}$$

This transforms homogeneously under endpoint gauge (Lemma 4.221) and preserves (4.110). A *wordwise parallel* section obeys $\mathbb{D}_\mu^{[\mathbf{W}]}|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}\rangle = 0$.

Lemma 4.279 (Leibniz rule and parallel constancy along a path)**.** *Let γ be a C^1 curve with pullback A_γ. If the word-locked frame condition holds at the readout end (Proposition 4.223) and $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}\rangle = 0$, then $\frac{d}{ds}\| \,|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(\gamma(s))\rangle\,\|^2 = 0$. Moreover, for any fibre observable $\hat O(x)$,*

$$\partial_\mu\langle\hat O\rangle^{[\mathbf{W}]}(x) = \Big\langle(\mathbb{D}_\mu^{[\mathbf{W}]})^\dagger\hat O(x)\Big\rangle^{[\mathbf{W}]} + \Big\langle\hat O(x)\,\mathbb{D}_\mu^{[\mathbf{W}]}\Big\rangle^{[\mathbf{W}]},$$

i.e. a covariant Leibniz rule holds (wordwise version of eq. (4.105)).

Proof. Let $x = \gamma(s)$ and write the dressed modal section in the wordwise orthonormal frame (cf. Proposition 4.258) as

$$|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle = \sum_{\mu\in\{0,1,p,s\}} c_\mu^{[\mathbf{W}]}(x)\,|\phi_\mu(x)\rangle, \qquad c^{[\mathbf{W}]}(x)\in\mathbb{C}^4.$$

Denote the wordwise connection one-form by $A_\mu^{[\mathbf{W}]}(x)\in\mathfrak{u}(4)$ (unitary gauge, cf. Proposition 4.167(a) and Proposition 4.276), and define the covariant derivative on coefficients

$$\mathbb{D}_\mu^{[\mathbf{W}]}c := \partial_\mu c + A_\mu^{[\mathbf{W}]}c, \qquad \Big(\mathbb{D}_\mu^{[\mathbf{W}]}c\Big)^\dagger = \partial_\mu c^\dagger + c^\dagger(A_\mu^{[\mathbf{W}]})^\dagger.$$

Along γ we write the pullback $A_\gamma(s) := \dot\gamma^\mu(s)\,A_\mu^{[\mathbf{W}]}(\gamma(s))$ and $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}c := \frac{d}{ds}c + A_\gamma c$.

Parallel constancy of the norm. Let $N(s) := \| \,|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(\gamma(s))\rangle\,\|^2 = c^\dagger(\gamma(s))\,c(\gamma(s))$. Then

$$\frac{dN}{ds} = \frac{dc^\dagger}{ds}\,c + c^\dagger\,\frac{dc}{ds} = \Big(\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}c\Big)^\dagger c + c^\dagger\Big(\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}c\Big) + c^\dagger\Big(A_\gamma + A_\gamma^\dagger\Big)c.$$

Since $A_\mu^{[\mathbf{W}]}\in\mathfrak{u}(4)$, we have $A_\gamma^\dagger = -A_\gamma$, hence the last term vanishes. If $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}\rangle = 0$ (equivalently, $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}c = 0$), then $\frac{d}{ds}N(s) = 0$, proving the first claim. The invocation of Proposition 4.223 guarantees that the *word-locked* readout frame is the one in which $A_\mu^{[\mathbf{W}]}$ is computed, so metric-compatibility ($A_\mu^{[\mathbf{W}]}\in\mathfrak{u}(4)$) applies at the endpoint.

Covariant Leibniz rule for expectations. For any fibre observable $\hat O(x)$, write its matrix in the wordwise frame as $O(x)$ and

$$\langle\hat O\rangle^{[\mathbf{W}]}(x) = \langle\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)|\,\hat O(x)\,|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle = c^\dagger(x)\,O(x)\,c(x).$$

Differentiate:

$$\partial_\mu\langle\hat O\rangle^{[\mathbf{W}]} = (\partial_\mu c^\dagger)Oc + c^\dagger(\partial_\mu O)c + c^\dagger O(\partial_\mu c).$$

Insert $\partial_\mu c = \mathbb{D}_\mu^{[\mathbf{W}]} c - A_\mu^{[\mathbf{W}]} c$ and its adjoint, and group terms to obtain

$$\partial_\mu \langle \hat{O} \rangle^{[\mathbf{W}]} = \big(\mathbb{D}_\mu^{[\mathbf{W}]} c\big)^\dagger O c + c^\dagger O \big(\mathbb{D}_\mu^{[\mathbf{W}]} c\big) + c^\dagger \Big(\partial_\mu O - (A_\mu^{[\mathbf{W}]})^\dagger O - O A_\mu^{[\mathbf{W}]}\Big) c.$$

By the *word-locked frame condition at readout* (cf. Proposition 4.223), fibre endomorphisms are identified in that local frame and regarded as *parallel-fixed*; equivalently,

$$\mathbb{D}_\mu^{[\mathbf{W}]} O := \partial_\mu O - (A_\mu^{[\mathbf{W}]})^\dagger O - O A_\mu^{[\mathbf{W}]} = 0 \quad \text{(fixed pairing, cf. eq. (4.105))}.$$

With this, the last bracket vanishes and we get

$$\partial_\mu \langle \hat{O} \rangle^{[\mathbf{W}]} = \Big\langle (\mathbb{D}_\mu^{[\mathbf{W}]})^\dagger \hat{O}(x) \Big\rangle^{[\mathbf{W}]} + \Big\langle \hat{O}(x)\, \mathbb{D}_\mu^{[\mathbf{W}]} \Big\rangle^{[\mathbf{W}]},$$

where the right-hand side is shorthand for $\langle (\mathbb{D}_\mu^{[\mathbf{W}]} \Psi) |\, \hat{O}\, |\Psi\rangle + \langle \Psi |\, \hat{O}\, (\mathbb{D}_\mu^{[\mathbf{W}]} \Psi)\rangle$. This is exactly the covariant Leibniz rule in the wordwise setting.

The two statements together establish Lemma 4.279. □

Definition 4.280 (Wordwise fibre density and expectations)**.** Set

$$\rho_{\text{modal}}^{[\mathbf{W}]}(x) := |\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle \langle \Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)|.$$

For any fibre observable $\hat{O}(x)$, define the expectation

$$\langle \hat{O} \rangle^{[\mathbf{W}]}(x) := \mathrm{Tr}\Big(\rho_{\text{modal}}^{[\mathbf{W}]}(x)\, \hat{O}(x)\Big),$$

which is invariant under endpoint gauge (Lemma 4.256).

Proposition 4.281 (Independence of p, s from twofold superpositions (wordwise))**.** *In any wordwise frame, the coefficients $c_p^{[\mathbf{W}]}(x)$ and $c_s^{[\mathbf{W}]}(x)$ weight independent fibre directions $|p\rangle_x^{[\mathbf{W},\chi]}$ and $|s\rangle_x^{[\mathbf{W},\chi]}$. They are not fixed by twofold superpositions inside* $\mathrm{span}\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\}$*; e.g. $|+\rangle_x^{[\mathbf{W},\chi]} = \frac{1}{\sqrt{2}}\big(|0\rangle_x^{[\mathbf{W},\chi]} + |1\rangle_x^{[\mathbf{W},\chi]}\big)$ is a twofold* effect*, not the fourfold basis vector $|p\rangle_x^{[\mathbf{W},\chi]}$ (*wordwise version of *Remark 4.269).*

Corollary 4.282 (Mode weights: gauge invariance and parallel constancy (wordwise))**.** *Let $P_\alpha^{[\mathbf{W}]}(x) = |\alpha\rangle_x^{[\mathbf{W},\chi]} \langle \alpha|_x^{[\mathbf{W},\chi]}$. Define $w_\alpha^{[\mathbf{W}]}(x) := \langle \Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x),\, P_\alpha^{[\mathbf{W}]}(x)\, \Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle$. Then $w_\alpha^{[\mathbf{W}]}(x)$ is invariant under endpoint gauge and, along any curve γ, is constant if $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} |\Psi_{\text{modal}}^{[\mathbf{W},\chi]}\rangle = 0$ and $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} P_\alpha^{[\mathbf{W}]} = 0$ (same propagation of projectors), cf. Corollary 4.272.*

Proof. Let $P_\alpha^{[\mathbf{W}]}(x) = |\alpha\rangle_x^{[\mathbf{W},\chi]} \langle \alpha|_x^{[\mathbf{W},\chi]}$ and

$$w_\alpha^{[\mathbf{W}]}(x) := \Big\langle \Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\,,\, P_\alpha^{[\mathbf{W}]}(x)\, \Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x) \Big\rangle.$$

Gauge invariance. Under an endpoint gauge $g(x) \in \mathrm{U}(4)$ on the modal fibre (wordwise gauge covariance; cf. Proposition 4.167(a) and Proposition 4.276),

$$|\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle \mapsto g(x)\, |\Psi_{\text{modal}}^{[\mathbf{W},\chi]}(x)\rangle, \qquad P_\alpha^{[\mathbf{W}]}(x) \mapsto g(x)\, P_\alpha^{[\mathbf{W}]}(x)\, g(x)^\dagger.$$

Hence

$$w_\alpha^{[\mathbf{W}]}(x) \;\mapsto\; \Big\langle g\Psi,\, gP_\alpha g^\dagger\, g\Psi \Big\rangle = \Big\langle \Psi,\, P_\alpha\, \Psi \Big\rangle = w_\alpha^{[\mathbf{W}]}(x),$$

using $g^\dagger g = I$ and unitarity of $g(x)$. Thus $w_\alpha^{[\mathbf{W}]}(x)$ is gauge invariant pointwise.

Parallel constancy along a curve. Let $x = \gamma(s)$ and denote $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]}$ the wordwise covariant derivative along γ (with pullback connection A_γ). By the covariant Leibniz rule established in Lemma 4.279, for any fibre observable $\hat O(x)$,

$$\frac{d}{ds}\,\langle \hat O\rangle^{[\mathbf{W}]}(\gamma(s)) = \Big\langle (\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]})^\dagger \hat O \Big\rangle^{[\mathbf{W}]} + \Big\langle \hat O\, \mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} \Big\rangle^{[\mathbf{W}]}.$$

Apply this with $\hat O = P_\alpha^{[\mathbf{W}]}$ and use the hypotheses $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} |\Psi_{\mathrm{modal}}^{[\mathbf{W},\chi]}\rangle = 0$ and $\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} P_\alpha^{[\mathbf{W}]} = 0$ ("same propagation of projectors"). Then both terms on the right vanish:

$$\Big\langle (\mathbb{D}_{\dot\gamma}^{[\mathbf{W}]})^\dagger P_\alpha^{[\mathbf{W}]} \Big\rangle^{[\mathbf{W}]} = 0, \qquad \Big\langle P_\alpha^{[\mathbf{W}]}\, \mathbb{D}_{\dot\gamma}^{[\mathbf{W}]} \Big\rangle^{[\mathbf{W}]} = 0,$$

so $\dfrac{d}{ds}\, w_\alpha^{[\mathbf{W}]}(\gamma(s)) = 0$.

This proves gauge invariance and parallel constancy of the wordwise mode weights, as claimed in Corollary 4.282. □

4.7 The Emergent Modal Space of a PQS

For each PQS $\mathfrak{B}_x$ at $x \in \mathcal{X}_q$, the intrinsic operator-theoretic structure

$$\hat{\mathbf{\Omega}}_x = {}_{\hat\Phi_x}\mathring{\mathbf{\Lambda}}_{x,\hat\Theta_x}$$

induces a local modal Hilbert space $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$. Its orthonormal basis $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ realizes the four irreducible dialectical modes (Symmetry, Antisymmetry, Parasymmetry, Holosymmetry). These are not merely labeled vectors; they are relationally constructed eigenmodes of the internal duality operator $\mathring{\mathbf{\Lambda}}_x$ and encode the full Fourfold Dialectic Algebra. Crucially, the inner product on $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$—and thus amplitudes, orthogonality, and measurement—is *defined* by the Fourfold Inter-Modal Correlator in the Quantum Holo-State (coincident limit), rather than imposed *a priori* (cf. eq. (4.85)). The kinematics of quantum theory (Hilbert geometry and Born weights) thereby become *emergent consequences* of a deeper, dialectically governed substrate.

From tensor products to fiber bundles Where conventional theory assembles composites via tensor products of fixed Hilbert spaces, the IQR replaces this scaffolding with a geometrically enriched architecture: the *Hilbert bundle of dialectic modes*

$$\mathscr{H}_{\mathrm{mod}} = \bigsqcup_{x\in\mathcal{X}_q} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$$

over the emergent configuration space $\mathcal{X}_q$ (cf. Definition 4.239). Each fiber is a locally constructed modal space with an inner product generated from correlators; fibers are compared

by gauge-covariant parallel transport. In this setting, coherence and entanglement are not externally imposed relations among static subsystems but *relational structures between fibers*, mediated by operator-valued channels and the connection that produces transport. Thus the modal Hilbert space of a PQS is the conceptual and physical successor to the qubit: a dynamically emergent, geometrically grounded structure that unifies internal logical modes, spatial locality, and informational coherence within one operator-theoretic framework—advancing beyond the abstract axioms toward a relationally enriched description of quantum reality.

Definition 4.283 (Wordwise Modal Hilbert Space of a PQS)**.** Fix $x \in \mathcal{X}_q$ with PQS $\mathfrak{B}_x$ (Definition 1.25) and choose a unitary device word $\mathbf{W} \in \langle \mathsf{A}_{\text{holo}} \rangle$ with control label χ. Let $\mathsf{W}_{\chi\leftarrow\chi}(x)$ be its RR element (Definition 4.148 and eq. (4.45)). The *wordwise modal Hilbert space* at x is the same fibre

$$\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4,$$

equipped with the emergent inner product induced by the Fourfold correlator in the Holo–state (Section 4.6 and eq. (4.85)). The *wordwise realization map*

$$\mathcal{R}_x^{[\mathbf{W},\chi]} : \{0,1,p,s\} \longrightarrow \mathbb{P}\Big(\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}\Big), \qquad \alpha \longmapsto \Big[\,|\alpha\rangle_x^{[\mathbf{W},\chi]}\,\Big],$$

is defined by the *word-rotated frame*

$$|\alpha\rangle_x^{[\mathbf{W},\chi]} := \mathsf{W}_{\chi\leftarrow\chi}(x)\,|\alpha\rangle_x, \qquad \alpha \in \{0,1,p,s\} \quad (\textit{Definition 4.257and Proposition 4.258}).$$

Wordwise orthonormal basis. Since $\mathsf{W}_{\chi\leftarrow\chi}(x)$ is unitary on the fibre, orthonormality is preserved:

$$\boxed{\Big\langle \alpha_x^{[\mathbf{W},\chi]} \;\Big|\; \beta_x^{[\mathbf{W},\chi]} \Big\rangle = \delta_{\alpha\beta}, \qquad \alpha,\beta \in \{0,1,p,s\} \quad (\text{cf. } \textit{eq.} \text{ (4.107})).} \tag{4.113}$$

Caution. $|p\rangle_x^{[\mathbf{W},\chi]}$ and $|s\rangle_x^{[\mathbf{W},\chi]}$ remain independent basis vectors. The twofold equal superposition $|+\rangle_x^{[\mathbf{W},\chi]} := \frac{1}{\sqrt{2}}\Big(|0\rangle_x^{[\mathbf{W},\chi]} + |1\rangle_x^{[\mathbf{W},\chi]}\Big)$ is a twofold *effect* and is not identified with $|p\rangle_x^{[\mathbf{W},\chi]}$ (Remark 4.269 and Proposition 4.281).

Wordwise modal decomposition. With $\mathcal{H}_{\alpha,x}^{[\mathbf{W}]} := \text{span}\{|\,\alpha\rangle_x^{[\mathbf{W},\chi]}\}$, one has

$$\boxed{\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} = \mathcal{H}_{0,x}^{[\mathbf{W}]} \oplus \mathcal{H}_{1,x}^{[\mathbf{W}]} \oplus \mathcal{H}_{p,x}^{[\mathbf{W}]} \oplus \mathcal{H}_{s,x}^{[\mathbf{W}]} \quad (\text{cf. } \textit{eq.} \text{ (4.108})).} \tag{4.114}$$

Wordwise state representation. Every $|\psi\rangle_x \in \mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ admits the expansion

$$|\psi\rangle_x = c_0^{[\mathbf{W}]}(x)\,|0\rangle_x^{[\mathbf{W},\chi]} + c_1^{[\mathbf{W}]}(x)\,|1\rangle_x^{[\mathbf{W},\chi]} + c_p^{[\mathbf{W}]}(x)\,|p\rangle_x^{[\mathbf{W},\chi]} + c_s^{[\mathbf{W}]}(x)\,|s\rangle_x^{[\mathbf{W},\chi]},$$

with pointwise normalization

$$\boxed{\Big|c_0^{[\mathbf{W}]}(x)\Big|^2 + \Big|c_1^{[\mathbf{W}]}(x)\Big|^2 + \Big|c_p^{[\mathbf{W}]}(x)\Big|^2 + \Big|c_s^{[\mathbf{W}]}(x)\Big|^2 = 1.} \tag{4.115}$$

Proposition 4.284 (Word/gauge covariance and invariance of the construction)**.** *For any endpoint gauge $g(x) \in \mathrm{U}(4)$ and any unitary words $\mathbf{W}, \mathbf{W}'$, the corresponding frames satisfy*

$$|\alpha\rangle_x^{[\mathbf{W}',\chi]} \;=\; U_{[\mathbf{W}',\mathbf{W}]}(x)\,|\alpha\rangle_x^{[\mathbf{W},\chi]}, \qquad U_{[\mathbf{W}',\mathbf{W}]}(x) := \mathsf{W}'_{\chi\leftarrow\chi}(x)\,\mathsf{W}_{\chi\leftarrow\chi}(x)^\dagger \in \mathrm{U}(4),$$

and $|\alpha\rangle_x^{[\mathbf{W},\chi]} \mapsto g(x)\,|\alpha\rangle_x^{[\mathbf{W},\chi]}$. Thus $\mathcal{R}_x^{[\mathbf{W},\chi]}$ changes by unitary conjugation, while $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$, the inner product (eq. (4.85)), the orthonormality (4.113), and the decomposition (4.114) are invariant.

Remark 4.285 (Connection/transport compatibility (wordwise at a point))**.** Along any path $\gamma : x' \to x$, frames and states obey the same unitary transport:

$$|\alpha\rangle_x^{[\mathbf{W},\chi]} = \mathcal{U}(x \leftarrow x';\gamma)\,|\alpha\rangle_{x'}^{[\mathbf{W},\chi]}, \qquad |\psi\rangle_x = \mathcal{U}(x \leftarrow x';\gamma)\,|\psi\rangle_{x'},$$

with $\mathcal{U} = \mathcal{P}\exp\!\big(-\int_\gamma \mathcal{A}\big)$ (Definition 4.248 and Proposition 4.249). Hence norms, orthonormality, and the modal split are preserved under parallel transport (the wordwise counterpart of Remark 4.267 and Lemma 4.270).

Interpretation (endogenous). The fibre $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ remains the relationally defined arena for the four modal facets, but is now *presented* via the word-rotated frame induced by a concrete device word. Different words give unitarily equivalent presentations (Prop. 4.284); measurements and inner products are unchanged, while the endogenous viewpoint keeps a tight link to operational realizations (control, lifted histories, and word-evaluated channels).

Remark 4.286 (Pointwise exogenous $\leftrightarrow$ endogenous dictionary)**.** At a fixed locus $x \in \mathcal{X}_q$, the exogenous (frame-based) and endogenous (word-rotated) presentations are related by the RR element of a unitary device word $\mathsf{W}_{\chi\leftarrow\chi}(x)$ (Definitions 4.148 and 4.257, eq. (4.45), and Proposition 4.258):

$$\begin{aligned}
&\text{(realization map)} && \mathcal{R}_x(\alpha) = [\,|\alpha\rangle_x\,] \;\longleftrightarrow\; \mathcal{R}_x^{[\mathbf{W},\chi]}(\alpha) = \Big[\,|\alpha\rangle_x^{[\mathbf{W},\chi]}\Big] \\
&&& \qquad\qquad = \Big[\,\mathsf{W}_{\chi\leftarrow\chi}(x)\,|\alpha\rangle_x\,\Big]; \\
&\text{(modal frame)} && \mathcal{B}_x = \{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\} \;\longleftrightarrow\; \mathcal{B}_x^{[\mathbf{W},\chi]} = \mathsf{W}_{\chi\leftarrow\chi}(x)\,\mathcal{B}_x; \\
&\text{(twofold superposition)} && |+\rangle_x = \tfrac{1}{\sqrt{2}}\big(|0\rangle_x + |1\rangle_x\big) \;\longleftrightarrow\; |+\rangle_x^{[\mathbf{W},\chi]} = \mathsf{W}_{\chi\leftarrow\chi}(x)\,|+\rangle_x.
\end{aligned}$$

The unitary conjugation preserves orthonormality (cf. eqs. (4.107) and (4.113)) and the modal decomposition (cf. eqs. (4.108) and (4.114)). *Caution (unchanged under conjugation):* the twofold effect $|+\rangle_x^{[\mathbf{W},\chi]}$ is not the parasymmetric basis vector $|p\rangle_x^{[\mathbf{W},\chi]}$; p, s remain independent directions (cf. Remark 4.269 and Proposition 4.281). By Proposition 4.284, different words (and endpoint gauges) change only the presentation via a unitary, leaving all fibrewise observables and pairings invariant.

4.7.1 Emergent Hilbert Space: GNS Realization and Modal Coupling

Definition 4.287 (Emergent Hilbert space via GNS and its modal role)**.** Let $\mathcal{A}$ be the unital C^*-algebra of emergent observables and let $\omega^{\overset{\circ}{\Psi}} : \mathcal{A} \to \mathbb{C}$ be the Holo-State. By the Gelfand–Naimark–Segal construction (Definition 1.34) there exists a cyclic $*$-representation

$$\left(\pi_{\overset{\circ}{\Psi}},\ \mathcal{H}_{\overset{\circ}{\Psi}},\ |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle\right)$$

such that $\omega^{\overset{\circ}{\Psi}}(A) = \langle\Omega_{\omega^{\overset{\circ}{\Psi}}}|\ \pi_{\overset{\circ}{\Psi}}(A)\ |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle$ for all $A \in \mathcal{A}$ and $\overline{\mathrm{span}}\{\pi_{\overset{\circ}{\Psi}}(A)|\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle : A \in \mathcal{A}\} = \mathcal{H}_{\overset{\circ}{\Psi}}$.

Definition. The **emergent Hilbert space** is

$$\mathcal{H}_{\mathrm{em}} \ :=\ \mathcal{H}_{\overset{\circ}{\Psi}},$$

with representation $\pi := \pi_{\overset{\circ}{\Psi}}$ and cyclic vector $|\Omega\rangle := |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle$. For any $A \in \mathcal{A}$ we set the represented ("hatted") operator $\hat{A} := \pi(A) \in \mathcal{B}(\mathcal{H}_{\mathrm{em}})$, so that $\langle\overset{\circ}{\Psi}|\cdot|\overset{\circ}{\Psi}\rangle = \langle\Omega|\cdot|\Omega\rangle = \omega^{\overset{\circ}{\Psi}}(\cdot)$ on $\mathcal{A}$.

Compatibility with the modal sector.

(i) *Carrier space for channels and transport.* All Fourfold correlator components and transporters live on $\mathcal{H}_{\mathrm{em}}$:

$$\hat{G}^{\alpha\beta}_{\Lambda}(x, x') \in \mathcal{B}(\mathcal{H}_{\mathrm{em}}), \qquad \mathcal{U}(x \leftarrow x'; \gamma) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}}),$$

with their gauge covariance and Hermitian symmetry as stated in Sections 4.1.2 and 4.1.4.

(ii) *Induced fiber metrics.* For each PQS locus $x \in \mathcal{X}_q$ the inner product on the modal fiber $\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$ is *generated* from $\mathcal{H}_{\mathrm{em}}$ by the Holo-State expectation of the Fourfold correlator in the coincident limit (cf. eq. (4.85)):

$$\langle\psi_1|\psi_2\rangle_x := \lim_{x' \to x} \langle\Omega|\,\hat{G}_{\Lambda}(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]\,|\Omega\rangle,$$

yielding the orthonormal modal basis and positivity discussed in Section 4.6.

(iii) *Hilbert bundle structure.* The collection of fibers $\{\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}\}_{x \in \mathcal{X}_q}$ organizes into the Hilbert bundle of dialectic modes $\mathscr{H}_{\mathrm{mod}} = \bigsqcup_{x \in \mathcal{X}_q} \mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$ (Definition 4.239); the connection whose path-ordered exponential is $\mathcal{U}$ implements gauge-covariant comparisons between fibers (Section 4.1.4).

Remark 4.288 (Uniqueness and Role)**.** The GNS representation $(\pi, \mathcal{H}_{\mathrm{em}}, |\Omega\rangle)$ is unique up to unitary equivalence; thus $\mathcal{H}_{\mathrm{em}}$ is determined by the pair $(\mathcal{A}, \omega^{\overset{\circ}{\Psi}})$. It serves as the universal carrier for represented observables, channel kernels, and parallel transporters, while *fiberwise* Hilbert geometries on $\mathcal{H}^{(\mathfrak{B}_x)}_{\mathrm{mod}}$ are *induced* from $\mathcal{H}_{\mathrm{em}}$ via the Fourfold correlator expectations. This realizes the slogan: global state $\Rightarrow$ GNS space $\mathcal{H}_{\mathrm{em}} \Rightarrow$ local fiber metrics.

Proposition 4.289 (Dimensional Profile and Ranks)**.** *Let $\mathcal{A}$ be the observable C^*-algebra and let $(\pi_{\overset{\circ}{\Psi}}, \mathcal{H}_{\overset{\circ}{\Psi}}, |\Omega_{\omega^{\overset{\circ}{\Psi}}}\rangle)$ be the GNS triple of the Holo-State $\omega^{\overset{\circ}{\Psi}}$. Write $\mathcal{H}_{\mathrm{em}} := \mathcal{H}_{\overset{\circ}{\Psi}}$. Then:*

(i) Emergent Hilbert space

$\mathcal{H}_{\mathrm{em}}$ is generally infinite-dimensional (typically separable). Its cardinal dimension depends on $(\mathcal{A}, \omega^{\overset{\circ}{\Psi}})$.

(ii) Modal fibers

For each locus $x \in \mathcal{X}_q$, the modal fiber is a rank-4 complex Hilbert space

$$\dim_{\mathbb{C}} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = 4,$$

with a direct-sum decomposition into four one-dimensional modal lines

$$\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = \mathcal{H}_{0,x} \oplus \mathcal{H}_{1,x} \oplus \mathcal{H}_{p,x} \oplus \mathcal{H}_{s,x}, \qquad \dim_{\mathbb{C}} \mathcal{H}_{\alpha,x} = 1.$$

(iii) Twofold vs. higher modes

The subspaces $\mathcal{H}_{(0,1),x} := \mathcal{H}_{0,x} \oplus \mathcal{H}_{1,x}$ and $\mathcal{H}_{(p,s),x} := \mathcal{H}_{p,x} \oplus \mathcal{H}_{s,x}$ have

$$\dim_{\mathbb{C}} \mathcal{H}_{(0,1),x} = \dim_{\mathbb{C}} \mathcal{H}_{(p,s),x} = 2.$$

(iv) Hilbert bundle of dialectic modes

The modal bundle $\pi : \mathcal{H}^{\mathrm{modal}} \to \mathcal{X}_q$ is a rank-4 complex Hermitian vector bundle, locally trivial as $\pi^{-1}(U) \cong U \times \mathbb{C}^4$. Its space of sections $\Gamma(\mathcal{X}_q, \mathcal{H}^{\mathrm{modal}})$ is typically infinite-dimensional.

(v) Correlator size in modal indices

The Fourfold inter-modal correlator has the block form

$$\hat{\mathbf{G}}_\Lambda(x, x') = [\hat{G}_\Lambda^{\alpha\beta}(x, x')]_{\alpha,\beta \in \{0,1,p,s\}}$$

i.e. a 4×4 matrix in modal indices with entries $\hat{G}_\Lambda^{\alpha\beta}(x, x') \in \mathcal{B}(\mathcal{H}_{\mathrm{em}})$. With the field–space refinement, one obtains a 2×2 matrix in field labels whose entries are themselves 4×4 in modal indices.

(vi) Operator spaces

$\mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is infinite-dimensional (and non-separable in the operator-norm topology even when $\mathcal{H}_{\mathrm{em}}$ is separable).

$$\boxed{\begin{aligned} \dim_{\mathbb{C}} \mathcal{H}_{\mathrm{em}} &= \infty \quad \text{(typically separable)}, \\ \dim_{\mathbb{C}} \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} &= 4, \\ \dim_{\mathbb{C}} \mathcal{H}_{\alpha,x} &= 1 \quad (\alpha \in \{0,1,p,s\}). \end{aligned}} \tag{4.116}$$

Remark 4.290 (Operator-Space Size and Why It Matters)**.** The symbol $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$ denotes the C^*-algebra of all bounded operators on the (typically separable, infinite-dimensional) emergent Hilbert space $\mathcal{H}_{\mathrm{em}}$. Two distinct facts are being emphasized:

(a) Infinite-dimensionality. Even when $\mathcal{H}_{\mathrm{em}}$ is separable, $\mathcal{B}(\mathcal{H}_{\mathrm{em}})$ is *vast*: it contains all bounded linear maps, including entangling channels, projectors onto arbitrary closed subspaces, conditional expectations, etc.

(b) Non-separability in operator norm. Although $\mathcal{H}_{\text{em}}$ may be separable (i.e. it has a countable dense subset), the metric space $\big(\mathcal{B}(\mathcal{H}_{\text{em}}), \|\cdot\|\big)$ is *not* separable. A standard proof sketch: fix an orthonormal basis $\{e_n\}_{n\in\mathbb{N}}$ of $\mathcal{H}_{\text{em}}$ and, for each subset $S \subseteq \mathbb{N}$, let $P_S \in \mathcal{B}(\mathcal{H}_{\text{em}})$ be the diagonal projection onto $\text{span}\{e_n : n \in S\}$. Then for $S \neq T$ the operator $P_S - P_T$ is diagonal with entries in $\{-1, 0, 1\}$ and hence $\|P_S - P_T\| = 1$. Thus $\{P_S : S \subseteq \mathbb{N}\}$ is an uncountable family that is 1-separated in operator norm, so no countable set can be dense. Therefore $\mathcal{B}(\mathcal{H}_{\text{em}})$ is non-separable in $\|\cdot\|$.

Why this matters for the Holo-State. The Fourfold correlator takes values in $\mathcal{B}(\mathcal{H}_{\text{em}})$, so the "space of allowed channels" is large enough to encode arbitrarily fine, genuinely global couplings. Later, when we show that the Quantum Holo-State is generally *not factorizable* across putative subsystem splits, we will not be relying on a small algebraic deficiency: even with a separable $\mathcal{H}_{\text{em}}$, the ambient observable algebra is big enough to support non-product (entangled, holistically constrained) states and dynamics. In short, separability of the *state space* does not imply separability (or any smallness) of the *operator space*; the latter's non-separable richness is precisely what allows nontrivial global structure to persist.

The framework inverts the traditional hierarchy "Hilbert space first, physics second." In the algebraic spirit, it is **algebra first, state first—then Hilbert space** [230, 241, 4]. The Hilbert space is not a pre-given arena; it is an outcome of deeper structural data. Two interconnected layers make this precise.

Global (GNS) layer. From the observable C^*-algebra $\mathcal{A}$ and the Quantum Holo-State $\omega^{\mathring{\mathbf{\Psi}}}$, the GNS construction produces the state-relative *emergent Hilbert space*

$$\mathcal{H}_{\text{em}} := \mathcal{H}_{\mathring{\mathbf{\Psi}}},$$

typically infinite-dimensional (often separable), which carries the representation in which all "hatted" operators act—fields, correlator entries, and parallel transporters [241, 230].

Local (fibered) layer. Alongside this global representation, the local degrees of freedom organize as a *rank-4 Hermitian vector bundle* over the emergent configuration space $\mathcal{X}_q$ [375, 225]. At each locus x (a Primordial Quantum Singularity) sits a four-dimensional modal fiber $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)} \cong \mathbb{C}^4$. In a radical departure from textbook practice, the fiber metric is *not assumed*; it is *generated* by taking the Holo-State expectation of the *Fourfold Inter-Modal Correlator* in the coincident limit, thereby defining orthogonality and amplitudes on each fiber [230, 241]. A gauge connection furnishes *parallel transport* between fibers; its curvature produces *holonomy*, which is operationally visible in the holosymmetric channels [375, 225].

This architecture differs sharply from the standard picture. There is *no fixed background arena*: both the global representation space and the local fiber metrics *emerge* from $(\mathcal{A}, \omega^{\mathring{\mathbf{\Psi}}})$ and from correlators [230, 241, 11]. Subsystems and entanglement are not read off a prior tensor factorization; they are inferred directly from *operator-valued kernels plus transport* [230, 11]. Moreover, each fiber carries the $\mathbb{Z}_2 \times \mathbb{Z}_2$–graded *Fourfold Dialectic Algebra*, which supplies selection rules for mixing among Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry [230, 241].

Bottom line. The result is a *relational, state-relative, fibered Hilbert geometry*: the "space of states" is not the stage for the theory—*it is one of the theory's outcomes*, carved by correlators, gauge transport, and the global Holo-State [230, 241, 375, 225].

4.7.2 Holonomy of the Modal Connection over PQS

The framework's Hilbert space is not a single, monolithic arena but a *fibered geometry*: local modal fibers are glued by a physical connection, and that gluing has observable consequences. On the Hilbert bundle of dialectic modes $(\mathscr{H}_{\mathrm{mod}}, \pi, \mathcal{X}_q)$ (cf. Definition 4.239), a skew-Hermitian connection one-form $\mathcal{A}$ generates the *parallel transporter* along a path $\gamma \subset \mathcal{X}_q$,

$$\mathcal{U}(x \leftarrow x'; \gamma) = \mathcal{P} \exp\Big(-\int_\gamma \mathcal{A} \Big), \qquad \mathcal{F} := \mathrm{d}\mathcal{A} + \mathcal{A} \wedge \mathcal{A}. \tag{4.117}$$

(cf. Section 4.1.4). For a closed loop ℓ based at x,

$$\mathrm{Hol}_\ell(x) := \mathcal{P}\, \exp\Big(-\oint_\ell \mathcal{A} \Big) \in \mathrm{U}(4)$$

is the *holonomy*. Flat regions ($\mathcal{F} \equiv 0$) on simply connected patches yield trivial holonomy; nonzero curvature or nontrivial topology produces a net, path-dependent twist.

Definition 4.291 (Holosymmetric loop operator)**.** Given a based loop ℓ at x with holonomy $\mathrm{Hol}_\ell \in \mathrm{U}(4)$ on the modal bundle, define

$$\hat{H}^{(s)}_\ell(x) := \hat{\mathcal{F}}^\dagger_s(x)\, \mathrm{Hol}_\ell\, \hat{\mathcal{F}}_s(x) \quad \in \mathcal{B}(\mathcal{H}_{\mathrm{em}}). \tag{4.118}$$

Its expectation in the Holo-State, $\omega^{\mathring{\mathbf{\Psi}}}\big(\hat{H}^{(s)}_\ell(x)\big)$, is the holonomy signal.

Loop readout in the holosymmetric channel. To turn holonomy into an operational signal, use the Fourfold channel structure (cf. Section 4.1.2). Let

$$\mathcal{U}_\ell(x) := \mathcal{U}(x \leftarrow x; \ell)$$

be the loop transporter along the closed path ℓ. The *holosymmetric loop operator* at x is

$$\hat{H}^{(s)}_\ell(x) \;:=\; \hat{\mathcal{F}}^\dagger_s(x)\, \mathcal{U}_\ell(x)\, \hat{\mathcal{F}}_s(x) \;=\; \hat{G}^{ss}_\Lambda(x, x; \ell), \tag{4.119}$$

i.e. the s–self channel of the Fourfold correlator with transport taken around ℓ (compare eq. (4.22)). Its expectation in the Holo-State gives a *holonomy signal*

$$h^{(s)}_\ell(x) \;:=\; \omega^{\mathring{\mathbf{\Psi}}}\big(\hat{H}^{(s)}_\ell(x)\big) \;=\; \Big\langle \mathring{\mathbf{\Psi}} \Big|\, \hat{H}^{(s)}_\ell(x) \,\Big|\, \mathring{\mathbf{\Psi}} \Big\rangle, \tag{4.120}$$

which is gauge-invariant (by the covariance of $\hat{\mathcal{F}}_s$ and $\mathcal{U}$; cf. Sections 4.1.2 and 4.1.4). In flat, contractible regions $h^{(s)}_\ell(x)$ is trivial; nontrivial values witness curvature or topology, the latter being directly analogous to Aharonov–Bohm–type behavior [378, 375].

Why the s–channel? Central coherence and cleanliness. The holosymmetric self–channel is (graded-)central in the Fourfold algebra (Postulate 4.4), so in flat regions it commutes with other modal transitions. Curvature introduces controlled deviations (eq. (4.75)). Consequently, $\hat{H}_\ell^{(s)}$ functions as a *stable coherence reference*: its phase/rotation around a loop cleanly reflects global structure, disentangled from local twofold interference.

Holonomy vs. singularity. Holonomy is not a "hole'' in space; it is a unitary memory of transport defined by the smooth connection $\mathcal{A}$. A classical singularity is a breakdown of geometry; by contrast, a Primordial Quantum Singularity (PQS) $\mathfrak{B}_x$ is an *algebraic seed* carrying the Fourfold Dialectic Algebra at x. The modal connection $\mathcal{A}$ lives on $\mathcal{X}_q$ *between* such loci and encodes how their local modal frames are glued; holonomy records the global twist of that gluing.

Metric compatibility and preservation under transport. With the fiber inner products generated from the correlator (cf. Section 4.6), the covariant derivative $\mathfrak{D}_\mu = \partial_\mu + \mathcal{A}_\mu$ satisfies the Leibniz rule

$$\partial_\mu \langle \Phi_{\text{modal}}, \Psi_{\text{modal}} \rangle_x = \Big\langle \mathfrak{D}_\mu \Phi_{\text{modal}}, \Psi_{\text{modal}} \Big\rangle_x + \Big\langle \Phi_{\text{modal}}, \mathfrak{D}_\mu \Psi_{\text{modal}} \Big\rangle_x . \tag{4.121}$$

so norms and orthonormal frames are preserved along parallel transport (cf. Lemma 4.270).

Conceptual upshot. Holonomy upgrades geometry into experiment: the connection that glues fibers *writes global structure into measurable phases*. The holosymmetric loop operator $\hat{H}_\ell^{(s)}$ is the calibrated dial that reads it. Flat transport erases the dial's deflection; curvature or nontrivial topology registers as a robust, implementation-invariant signal in the s–channel.

4.7.3 Wordwise Holonomy of the Modal Connection over PQS

We view holonomy operationally via word-evaluated channels and word-rotated frames (Definitions 4.148, 4.255 and 4.257 and eq. (4.45)). The base connection $\mathcal{A}$ and transporter $\mathcal{U} = \mathcal{P}\exp(-\int \mathcal{A})$ remain exactly as in the exogenous formulation (Definitions 4.56 and 4.248 and Proposition 4.249).

Definition 4.292 (Wordwise loop transporter and holonomy)**.** For a closed loop ℓ based at x, the loop transporter in the modal bundle is

$$\mathcal{U}_\ell(x) := \mathcal{U}(x \leftarrow x; \ell) = \mathcal{P}\,\exp\Big(-\oint_\ell \mathcal{A} \Big) \in \mathrm{U}(4) \quad (\textit{Definition 4.56}).$$

Fix a unitary device word $\mathbf{W}$ and control χ. The *wordwise holosymmetric loop operator* is

$$\boxed{\hat{H}_\ell^{(s)[\mathbf{W}]}(x) \;:=\; \Big(\hat{\mathcal{F}}_s^{[\mathbf{W};\,\chi\leftarrow\chi]}(x)\Big)^\dagger \mathcal{U}_\ell(x)\, \hat{\mathcal{F}}_s^{[\mathbf{W};\,\chi\leftarrow\chi]}(x) \;=\; \hat{G}_\Lambda^{ss}\Big(x, x; \mathbf{W}, \chi\leftarrow\chi; \ell\Big),} \tag{4.122}$$

i.e. the s–self word-evaluated channel around the loop (Definition 4.166 and eq. (4.66)).

Definition 4.293 (Wordwise holonomy signal)**.** With the Holo-State functional $\omega^{\mathring{\Psi}}(\cdot)$, define the *wordwise holonomy signal*

$$\boxed{h_\ell^{(s)[\mathbf{W}]}(x) \;:=\; \omega^{\mathring{\Psi}}\Big(\hat{H}_\ell^{(s)[\mathbf{W}]}(x)\Big) \;=\; \Big\langle \mathring{\Psi}\Big|\, \hat{H}_\ell^{(s)[\mathbf{W}]}(x)\,\Big|\mathring{\Psi}\Big\rangle.} \tag{4.123}$$

Proposition 4.294 (Gauge covariance and invariances)**.** *Under an endpoint gauge $g : \mathcal{X}_q \to \mathrm{U}(4)$,*

$$\mathcal{U}_\ell(x) \mapsto g(x)\,\mathcal{U}_\ell(x)\,g(x)^\dagger, \qquad \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x) \mapsto g(x)\,\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x),$$

and hence

$$\hat{H}_\ell^{(s)[\mathbf{W}]}(x) \;\mapsto\; g(x)\,\hat{H}_\ell^{(s)[\mathbf{W}]}(x)\,g(x)^\dagger,$$

so the Born scalar $h_\ell^{(s)[\mathbf{W}]}(x)$ in (4.123) is gauge-invariant (Proposition 4.54 and Corollary 4.64). Moreover, replacing $\mathbf{W}$ by another unitary word $\mathbf{W}'$ conjugates $\hat{H}_\ell^{(s)[\mathbf{W}]}(x)$ by a unitary $U_{[\mathbf{W}',\mathbf{W}]}(x)$ (Proposition 4.284), hence preserves its spectrum and any trace-based invariants.

Proof. Fix $x \in \mathcal{X}_q$ and a loop/segment ℓ based at x. Write the wordwise s–selector as a fibre ket $\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)$ and its rank-one projector $P_s^{[\mathbf{W}]}(x) := \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)\,\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)^\dagger$. Let the (endpoint) holonomy/transport be $\mathcal{U}_\ell(x)$. Define the wordwise holonomy operator

$$\hat{H}_\ell^{(s)[\mathbf{W}]}(x) \;:=\; \mathcal{U}_\ell(x)\,P_s^{[\mathbf{W}]}(x). \tag{4.124}$$

Gauge covariance. Under an endpoint gauge $g : \mathcal{X}_q \to \mathrm{U}(4)$ one has

$$\begin{aligned} \mathcal{U}_\ell(x) &\mapsto g(x)\,\mathcal{U}_\ell(x)\,g(x)^\dagger \quad \text{by } \textit{Proposition } 4.54, \\ \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x) &\mapsto g(x)\,\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x) \text{ by } \textit{Corollary } 4.64. \end{aligned} \tag{4.125}$$

Hence $P_s^{[\mathbf{W}]}(x) \mapsto g(x)\,P_s^{[\mathbf{W}]}(x)\,g(x)^\dagger$, and from (4.124) it follows that

$$\hat{H}_\ell^{(s)[\mathbf{W}]}(x) \;\mapsto\; g(x)\,\hat{H}_\ell^{(s)[\mathbf{W}]}(x)\,g(x)^\dagger.$$

Let the Born scalar $h_\ell^{(s)[\mathbf{W}]}(x)$ be the (normalized) expectation appearing in eq. (4.123). Since the state transforms as $|\Psi(x)\rangle \mapsto g(x)|\Psi(x)\rangle$ (endpoint action) and $g(x)$ is unitary,

$$h_\ell^{(s)[\mathbf{W}]}(x) = \langle\Psi(x)|\,\hat{H}_\ell^{(s)[\mathbf{W}]}(x)\,|\Psi(x)\rangle \;\longmapsto\; \langle\Psi|\,g^\dagger g\,\hat{H}_\ell^{(s)[\mathbf{W}]}(x)\,g^\dagger g\,|\Psi\rangle = h_\ell^{(s)[\mathbf{W}]}(x),$$

so the scalar is gauge-invariant.

Invariance under unitary word changes. Let $\mathbf{W}'$ be another *unitary* word. By wordwise modal invariance (Proposition 4.284), there exists a unitary $U_{[\mathbf{W}',\mathbf{W}]}(x) \in \mathrm{U}(4)$ such that, at the endpoint x,

$$\hat{\mathcal{F}}_s^{[\mathbf{W}';\chi\leftarrow\chi]}(x) = U_{[\mathbf{W}',\mathbf{W}]}(x)\,\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x), \qquad \mathcal{U}_\ell^{[\mathbf{W}']}(x) = U_{[\mathbf{W}',\mathbf{W}]}(x)\,\mathcal{U}_\ell^{[\mathbf{W}]}(x)\,U_{[\mathbf{W}',\mathbf{W}]}(x)^\dagger,$$

(the latter being the same geometric transport written in the rotated word-locked frame). Consequently,

$$P_s^{[\mathbf{W}']}(x) = \hat{\mathcal{F}}_s^{[\mathbf{W}']}\hat{\mathcal{F}}_s^{[\mathbf{W}']\dagger} = U_{[\mathbf{W}',\mathbf{W}]}\, P_s^{[\mathbf{W}]}\, U_{[\mathbf{W}',\mathbf{W}]}^{\dagger},$$

and, using (4.124),

$$\begin{aligned}\hat{H}_\ell^{(s)[\mathbf{W}']}(x) &= \mathcal{U}_\ell^{[\mathbf{W}']}(x) P_s^{[\mathbf{W}']}(x) \\ &= U_{[\mathbf{W}',\mathbf{W}]}(x)\left(\mathcal{U}_\ell^{[\mathbf{W}]}(x) P_s^{[\mathbf{W}]}(x)\right) U_{[\mathbf{W}',\mathbf{W}]}(x)^\dagger \\ &= U_{[\mathbf{W}',\mathbf{W}]}(x)\, \hat{H}_\ell^{(s)[\mathbf{W}]}(x)\, U_{[\mathbf{W}',\mathbf{W}]}(x)^\dagger. \end{aligned} \tag{4.126}$$

Thus $\hat{H}_\ell^{(s)[\mathbf{W}']}(x)$ is unitarily similar to $\hat{H}_\ell^{(s)[\mathbf{W}]}(x)$, so they have the same spectrum and the same values of any trace-based invariant (e.g. $\mathrm{tr}[\hat{H}^k]$, characteristic polynomial coefficients), as claimed.

This proves Proposition 4.294. □

Proposition 4.295 (Flatness ⇒ trivial wordwise holonomy (on simply connected patches))**.** *If $\mathcal{F} = 0$ on a simply connected neighbourhood of ℓ, then $\mathcal{U}_\ell(x) = \mathbf{1}_4$ and*

$$\hat{H}_\ell^{(s)[\mathbf{W}]}(x) = \left(\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)\right)^\dagger \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x), \tag{4.127}$$

so $h_\ell^{(s)[\mathbf{W}]}(x)$ reduces to the baseline s–channel self–correlator at the point (Propositions 4.224 and 4.264).

Proof. Let $U \subset \mathcal{X}_q$ be a simply connected neighbourhood containing the image of the loop ℓ based at x, and let $A^{[\mathbf{W}]}$ denote the wordwise connection one–form on the modal fibre with curvature $\mathcal{F} := \mathrm{d}A^{[\mathbf{W}]} + A^{[\mathbf{W}]} \wedge A^{[\mathbf{W}]}$. Assume $\mathcal{F} = 0$ on U.

Step 1: Flat ⇒ path–independent transport (and trivial loop holonomy). By the wordwise curvature/flatness statements (Propositions 4.224 and 4.264), flatness on a simply connected domain implies that parallel transport depends only on endpoints, i.e. for any two C^1 paths $\gamma_1, \gamma_2 : x' \to x$ in U, $\mathcal{U}(x \leftarrow x'; \gamma_1) = \mathcal{U}(x \leftarrow x'; \gamma_2)$. Equivalently, the holonomy around any contractible loop in U is the identity:

$$\mathcal{U}_\ell(x) = \mathbf{1}_4. \tag{4.128}$$

One way to see (4.128) directly is via the gauge–trivialization guaranteed by flatness on U: there exists $g : U \to \mathrm{U}(4)$ such that the transformed connection vanishes, $A^g = 0$ (local pure gauge). In that gauge the parallel transport along *any* path is the identity map, hence $\mathcal{U}_\ell^g(x) = \mathbf{1}_4$. By endpoint gauge covariance (Proposition 4.54), $\mathcal{U}_\ell^g(x) = g(x)\,\mathcal{U}_\ell(x)\,g(x)^\dagger$, and since $g(x)$ is unitary, this implies $\mathcal{U}_\ell(x) = \mathbf{1}_4$.

Step 2: Wordwise loop operator collapses to the baseline s–channel correlator. Recall the wordwise s–channel holonomy operator along ℓ (in the word–locked readout frame at x):

$$\hat{H}_\ell^{(s)[\mathbf{W}]}(x) = \left(\hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x)\right)^\dagger \mathcal{U}_\ell(x)\, \hat{\mathcal{F}}_s^{[\mathbf{W};\chi\leftarrow\chi]}(x) \quad \text{(cf. eq. (4.122))}. \tag{4.129}$$

Insert (4.128) into (4.129) to obtain

$$\hat{H}_{\ell}^{(s)[\mathbf{W}]}(x) = \Big(\hat{\mathcal{F}}_{s}^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^{\dagger}\hat{\mathcal{F}}_{s}^{[\mathbf{W};\chi\leftarrow\chi]}(x),$$

which is exactly eq. (4.127). In particular, the associated Born scalar $h_{\ell}^{(s)[\mathbf{W}]}(x)$ (cf. eq. (4.123)) reduces to the baseline s–channel self–correlator at the point x.

This proves Proposition 4.295. □

Remark 4.296 (Operational readout via wordwise channels)**.** The equality (4.122) shows that holonomy is directly encoded in an s–self word-evaluated channel; interferometric protocols that isolate the s–channel (e.g. via Hadamard sum/difference and centrality of ss under the words-only meta-claim, Proposition 4.176 and Corollary 4.225) provide clean access to $h_{\ell}^{(s)[\mathbf{W}]}(x)$. In flat, contractible regions the signal is trivial (Proposition 4.295); nontrivial values witness curvature or topology, in direct analogy with Aharonov–Bohm–type phases, but here recorded by the holosymmetric channel.

Remark 4.297 (Why the s–channel in the wordwise setting)**.** Under the words-only meta-claim conditions (Proposition 4.176), the ss block is central to leading order, while the ps/sp edge is nilpotent; hence the loop operator $\hat{H}_{\ell}^{(s)[\mathbf{W}]}$ serves as a stable coherence reference, with deviations from centrality controlled by the compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178 and Proposition 4.181).

Corollary 4.298 (Wordwise small-loop sensitivity (first order))**.** *Let ℓ_{ε} be a family of contractible loops of area $O(\varepsilon^2)$ based at x. Then*

$$\hat{H}_{\ell_{\varepsilon}}^{(s)[\mathbf{W}]}(x) = \Big(\hat{\mathcal{F}}_{s}^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^{\dagger}\Big(\mathbf{1}_4 - \varepsilon^2\,\Phi_x(\mathcal{F}) + O(\varepsilon^3)\Big)\hat{\mathcal{F}}_{s}^{[\mathbf{W};\chi\leftarrow\chi]}(x),$$

for a linear functional $\Phi_x(\mathcal{F})$ of the curvature two–form determined by the loop's oriented area (non–Abelian Stokes expansion). Consequently, $h_{\ell_{\varepsilon}}^{(s)[\mathbf{W}]}(x) = h_{\mathrm{flat}}^{(s)[\mathbf{W}]}(x) - \varepsilon^2\,\omega^{\mathring{\Psi}}\Big((\hat{\mathcal{F}}_{s}^{[\cdot]})^{\dagger}\Phi_x(\mathcal{F})\hat{\mathcal{F}}_{s}^{[\cdot]}\Big) + O(\varepsilon^3)$.

Idea. Use the Dyson expansion of $\mathcal{P}\exp(-\oint_{\ell}\mathcal{A})$ and the non–Abelian Stokes theorem to first order in the loop area; insert into (4.122) and evaluate the expectation. □

Proof. Fix a smooth oriented disk Σ_{ε} with $\partial\Sigma_{\varepsilon} = \ell_{\varepsilon}$ based at x. By endpoint gauge covariance (Proposition 4.54) choose a local gauge with $g(x) = \mathbf{1}$ and $\mathcal{A}_{\mu}(x) = 0$ (e.g. radial/normal gauge around x). Write the loop holonomy $\mathcal{U}_{\ell_{\varepsilon}}(x) = \mathcal{P}\exp\Big(-\oint_{\ell_{\varepsilon}}\mathcal{A}\Big) \in \mathrm{U}(4)$ (Definition 4.56), and expand the path–ordered exponential by the Dyson series. Because $\mathcal{A}(x) = 0$ and ℓ_{ε} has linear size $O(\varepsilon)$, the first nontrivial contribution is $O(\varepsilon^2)$. Using Stokes' theorem together with the definition of curvature $\mathcal{F} = \mathrm{d}\mathcal{A} + \mathcal{A}\wedge\mathcal{A}$ (Definition 4.56) and the standard (non–Abelian) small–loop expansion, one obtains

$$\mathcal{U}_{\ell_{\varepsilon}}(x) = \mathbf{1}_4 - \int_{\Sigma_{\varepsilon}}\mathcal{F}(x) + O(\varepsilon^3) = \mathbf{1}_4 - \Phi_x(\mathcal{F}) + O(\varepsilon^3), \tag{4.130}$$

where the linear functional $\Phi_x(\mathcal{F})$ is the contraction of $\mathcal{F}$ at x with the oriented area bivector of Σ_ε:

$$\Phi_x(\mathcal{F}) \;:=\; \sum_{\mu<\nu} \Sigma^{\mu\nu}(\ell_\varepsilon)\, \mathcal{F}_{\mu\nu}(x), \qquad \Sigma^{\mu\nu}(\ell_\varepsilon) := \int_{\Sigma_\varepsilon} d\sigma^{\mu\nu}\,,$$

so $\Phi_x(\mathcal{F}) = O(\varepsilon^2)$. The $O(\varepsilon^3)$ remainder collects (i) higher Dyson terms and (ii) Taylor errors from replacing $\mathcal{F}(y)$ by $\mathcal{F}(x)$ inside the surface integral; both scale as area×diameter $= O(\varepsilon^3)$. The appearance of $\mathcal{F}$ as the infinitesimal generator of noncommutativity is consistent with the curvature identity $[\mathbb{D}^{[\cdot]}_\mu, \mathbb{D}^{[\cdot]}_\nu]X = [\mathcal{F}_{\mu\nu}, X]$ (Proposition 4.224).

IInsert (4.130) into the wordwise s–loop operator

$$\hat{H}^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = \Big(\hat{\mathcal{F}}^{[\mathbf{W};\chi\leftarrow\chi]}_s(x)\Big)^\dagger \mathcal{U}_{\ell_\varepsilon}(x)\, \hat{\mathcal{F}}^{[\mathbf{W};\chi\leftarrow\chi]}_s(x)$$

(eq. (4.122)) to get

$$\hat{H}^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = \Big(\hat{\mathcal{F}}^{[\mathbf{W};\chi\leftarrow\chi]}_s(x)\Big)^\dagger \Big(\mathbf{1}_4 - \Phi_x(\mathcal{F}) + O(\varepsilon^3)\Big) \hat{\mathcal{F}}^{[\mathbf{W};\chi\leftarrow\chi]}_s(x),$$

which is the stated operator expansion (recall $\Phi_x(\mathcal{F}) = O(\varepsilon^2)$). Taking the Holo–State expectation (eq. (4.123)) yields

$$h^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = \underbrace{\omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}^{[\cdot]}_s)^\dagger \hat{\mathcal{F}}^{[\cdot]}_s\Big)}_{=:\; h^{(s)[\mathbf{W}]}_{\mathrm{flat}}(x)} - \omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}^{[\cdot]}_s)^\dagger\, \Phi_x(\mathcal{F})\, \hat{\mathcal{F}}^{[\cdot]}_s\Big) \;+\; O(\varepsilon^3),$$

i.e. $h^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = h^{(s)[\mathbf{W}]}_{\mathrm{flat}}(x) - \varepsilon^2\, \omega^{\mathring{\mathbf{\Psi}}}\Big((\hat{\mathcal{F}}^{[\cdot]}_s)^\dagger \Phi_x(\mathcal{F}) \hat{\mathcal{F}}^{[\cdot]}_s\Big) + O(\varepsilon^3)$. Gauge covariance of $\mathcal{U}$ and the endpoint fields (Propositions 4.54 and 4.294 and Corollary 4.64) implies that $\hat{H}^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x)$ transforms by conjugation, hence the scalar $h^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x)$ is gauge invariant; in the flat, simply connected case $\mathcal{F} \equiv 0$ one recovers the trivial loop value (Proposition 4.295). □

How Quantum Logic Weaves Spacetime

Outcome, not stage. *Geometry is inferred, not assumed.* Distances, causal dispositions, and the very notions of "where" and "when" are read as *expectation values* of the Fourfold inter-modal correlator in the Holo-State (Definition 4.9, Section 4.6, and eq. (4.85)). This is *operational background independence*: the same quantum relations that glue local modal fibres into a bundle (Definitions 4.239 and 4.247) also generate the geometric data that later constrain those relations via the connection $\mathcal{A}$ and its transporter $\mathcal{U}$ (Definition 4.248 and Section 4.1.4). In this way, the framework closes the classic GR–QFT gap by letting the "arena" itself be *derived* from correlator structure.

State-relative arena and learned subsystems. The working Hilbert space is *state-relative*: the physically active subspace and observables are carved out by the actual Holo-State $\omega^{\mathring{\mathbf{\Psi}}}$ through the modal fibre and its inner product (Definition 4.266 and eqs. (4.100) and (4.102)). There is likewise *no a priori tensor product*: "subsystems" are *learned* from (i) the Fourfold

block structure and its off-diagonal couplings (Definition 4.81 and Proposition 4.246), and (ii) the connection that transports modal data between loci (Definition 4.248). Entanglement is therefore not merely "in'' spacetime; it is part of the mechanism that *weaves* it, via transport and gluing of sections (Remark 4.267, Lemma 4.270, and Corollary 4.251).

Logic → law: selection rules from the Fourfold. Kinematics and dynamics are constrained by a *Fourfold Dialectic Algebra* with $\mathbb{Z}_2 \times \mathbb{Z}_2$ grading (Section 4.1.7 and Definition 4.94). The gradings act as *selection rules* on allowable inter-modal moves. In the endogenous, wordwise reading this appears constructively as the "words-only trio'': central ss, nilpotent ps/sp, and bosonic $0/s$ compatibility (Proposition 4.176). When coherence is lost, the theory *collapses to the Twofold block* (Thesis/Antithesis), realized here as the $(0,1)$ subbundle (Definition 4.245) with suppressed mixing into (p,s) when the relevant off-diagonal channels are small (Proposition 4.246). Thus the classical rules (non-contradiction, excluded middle) arise as a modal limit that the logic itself predicts.

A unified venue and new observables. Geometry and matter share a *common correlator architecture*—a 2×2 field block whose entries are 4×4 in modal space—so their co-emergence is described in a single venue through the Fourfold correlator (Definitions 4.9 and 4.81). This architecture suggests concrete, testable quantities: *holonomies* of the modal connection (Section 4.7.2). Transporting a mode around a closed loop ℓ yields a measurable change captured by the holosymmetric loop operator $\hat{H}_\ell^{(s)}(x) = \hat{G}_\Lambda^{ss}(x,x;\ell)$ and its expectation (eqs. (4.119) and (4.120)); in the endogenous calculus, the same signal is extracted from the word-evaluated s–self channel (Section 4.7.3 and eqs. (4.122) and (4.123)). Flat, simply connected regions trivialize the loop (Corollary 4.251 and Proposition 4.295); nonzero curvature or nontrivial topology produce robust, implementation-invariant phases (Aharonov–Bohm–type phenomena).

From ideas to inequalities. Because the framework is operational, intuition is pinned down by *bounds*. The holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178) controls measurable diagnostics—visibility envelopes, lensing residuals, two-step ps/sp amplitudes, and diagonal pinching—via Proposition 4.181 (with pinching stability in Lemma 4.180 and its exact conditional-expectation form in Remark 4.182). Thus departures from idealized logic are *quantified* and experimentally targetable.

Conceptual upshot (relational geometry, derived). Reality = relations. Physics is reframed as a *relational, graded, fibered Hilbert geometry* whose structures are *derived* from quantum-logical correlators rather than stipulated. The "space of states'' (global sections and their inner products, Definition 4.266 and Remark 4.268) and the "spacetime of events'' (glued by $\mathcal{A}$ and probed by holonomy, Definition 4.248 and Section 4.7.2) are outputs of the same engine. If borne out, this turns the usual scaffolding inside-out—and provides new levers (holonomy signals and compliance-vector diagnostics) to test how the universe *knits itself together* (Section 4.7.3 and Proposition 4.181).

4.7.4 The Abstract Qubit

From abstract bits to emergent modal structures. The transition from the conventional *qubit* to the *modal Hilbert space of a Primordial Quantum Singularity* (PQS) is a principled relocation of abstraction. In standard quantum mechanics, a qubit is an axiomatic object—an element of the isomorphism class of pairs $(\mathbb{C}^2, \langle\cdot,\cdot\rangle)$ endowed with the Born rule [379]. By contrast, within the IQR framework the relevant degrees of freedom are *localized, emergent phenomena*: the modal fibres $\mathcal{H}_{\text{mod}}(\mathfrak{B}_x)$ of a globally structured Hilbert bundle whose metric data are *induced* rather than postulated, and whose geometry is fixed by the correlator-driven fourfold dialectical structure (Definitions 4.9 and 4.273, Remark 4.253, and Sections 4.1.2 and 4.1.3). In this relocation, an "elementary quantum of information'' is not a static amplitude container but a *context-sensitive nexus of relations* determined by inter-PQS structure across the emergent configuration space $\mathcal{X}_q$.

The Abstract Qubit (Effective Limit). The conventional qubit is a unit vector in a fixed two-dimensional space $\mathcal{H} \cong \mathbb{C}^2$,

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle, \qquad \alpha,\beta \in \mathbb{C}, \quad |\alpha|^2 + |\beta|^2 = 1,$$

with statistics supplied by the Born rule and multi-qubit structure given by $\mathcal{H}_2^{\otimes n}$. This architecture presupposes a background Hilbert space and does not itself encode emergent state-space geometry or internal dialectical dynamics. Laboratory implementations (ions, superconductors, photons, NV, quantum dots) instantiate this abstraction but decohere, motivating error correction [351, 380, 349]. IQR does not dispute any of this; it *relocates* the qubit, showing it as an *effective* face of a deeper, correlator-induced modal geometry.

State-dependent Arena via GNS and the Fourfold

At the foundational level, the Fourfold Dialectic Algebra of Symmetry provides the $*$-algebraic substrate; the universal Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ endows it with expectations, and the GNS construction yields the concrete representation $(\pi_\Psi, \mathcal{H}_{\text{em}}, |\Omega_\Psi\rangle)$ (Section 1.4.2 and Definition 1.27). In particular, the *inner product on each modal fibre* is defined by the coincident-limit of the Fourfold Inter-Modal Correlator evaluated in $|\mathring{\mathbf{\Psi}}\rangle$ (Section 4.6 and Definition 4.228). Thus the *Hilbert arena is state-dependent*: representation first, background later.

Remark 4.299 (Relational Emergence of Modal Geometry)**.** The modal fibre $\mathcal{H}_{\text{mod}}(\mathfrak{B}_x)$ is fixed only relationally—by its couplings to neighbouring singularities $\mathfrak{B}_{x'}$ through $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ and by the global state $|\mathring{\mathbf{\Psi}}\rangle$. This implements, at the operator level, the dictum that distinguishability and geometry crystallize *between* PQSs rather than *at* them.

Twofold Poles Within a Genuinely Fourfold Fibre

Inside each fibre $\mathcal{H}_{\text{mod}}^{(\mathfrak{B}_x)}$ there are four ontological modes $\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ realising Symmetry, Antisymmetry, Parasymmetry, and Holosymmetry (Sections 1.2.7 and 2.1). The pair $|0\rangle_x, |1\rangle_x$ plays the role of *dyadic poles* of the Twofold sector, but only *after* the fibre's inner product has been *emergently fixed* from the correlator; by construction, $|p\rangle_x$ and $|s\rangle_x$ are

independent basis rays—not mere superpositions within the Twofold qubit dyad (Section 4.6). Hence the qubit-like axis is *recovered* as an internal sector of a genuinely Fourfold modality, not presupposed.

Qubit Reduction Theorem

Proposition 4.300 (Qubit Reduction)**.** *Assume that at $\mathfrak{B}_x$ there exist two orthonormal modal rays $|\alpha_x\rangle, |\beta_x\rangle \in \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ stabilised by the local dialectic generators, and that the inter-modal couplings are block-diagonalisable so that back-reaction on $S_x := \mathrm{span}\{|\alpha_x\rangle, |\beta_x\rangle\}$ is negligible over the control timescale. Then there exists an isometric embedding $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ with $U|0\rangle = |\alpha_x\rangle$ and $U|1\rangle = |\beta_x\rangle$, such that:*

(i) Born statistics on $\mathbb{C}^2$ agree with those induced by the emergent fibre inner product on $\mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ (as defined via the correlator/GNS machinery in Section 4.6), and

(ii) admissible local controls act (on S_x) as an effective SU(2)*.*

Proof. Step 0 (Set-up). Work in any orthonormal trivialisation $(\mathcal{U}, e_{\mathcal{U}})$ around x with fibre inner product $\langle\cdot,\cdot\rangle_x$. The scalar pairing of sections is independent of trivialisation and G-gauge, by Lemma 4.270 (in particular (1) therein). Hence all constructions below are intrinsic to the fibre at x.

Step 1 (Isometric embedding). Since $\{|\alpha_x\rangle, |\beta_x\rangle\}$ is an orthonormal pair in $\mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$, define $U : \mathbb{C}^2 \to \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ by $U|0\rangle = |\alpha_x\rangle$, $U|1\rangle = |\beta_x\rangle$ and extend linearly. Then, for any $|\phi\rangle, |\psi\rangle \in \mathbb{C}^2$,

$$\langle \phi, \psi\rangle_{\mathbb{C}^2} = \langle U\phi, U\psi\rangle_x,$$

so U is an isometry onto $S_x = \mathrm{span}\{|\alpha_x\rangle, |\beta_x\rangle\}$. (This uses only orthonormality in the emergent fibre metric; cf. the construction preceding Proposition 4.300.)

Step 2 (Born statistics agree). Let E be any effect on $\mathbb{C}^2$ (i.e. $0 \le E \le \mathbb{1}_2$). Define the corresponding fibre effect $\widetilde{E} := UEU^\dagger$ acting on $\mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$. For any $|\psi\rangle \in \mathbb{C}^2$,

$$\langle\psi|E|\psi\rangle = \langle U\psi|\, UEU^\dagger\, |U\psi\rangle_x = \langle U\psi|\, \widetilde{E}\, |U\psi\rangle_x,$$

so Born valuations coincide by isometry. Moreover, the map $E \mapsto \widetilde{E} = UEU^\dagger$ is a unital $*$-monomorphism of effect algebras and therefore preserves POVMs, making the operational equivalence explicit. Since the modal inner product is induced by the Fourfold Inter-Modal Correlator via the GNS state (the state-dependent arena mechanism), this establishes (i).

Step 3 (Effective SU(2) *controls on S_x).* Let $\mathfrak{A}_x$ denote the Lie algebra of admissible local control generators at x (skew-Hermitian operators produced by the local dialectic generators/connection; see the covariant Leibniz setting). Stabilisation of the rays means S_x is invariant: for every $A \in \mathfrak{A}_x$, $AS_x \subseteq S_x$. Let P be the orthogonal projector onto S_x and define the compressed representation $\rho : \mathfrak{A}_x \to \mathfrak{u}(2)$ by $\rho(A) = PAP|_{S_x}$. Then $\rho(\mathfrak{A}_x)$ is a Lie subalgebra of $\mathfrak{u}(2)$. If $\rho(\mathfrak{A}_x)$ contains two linearly independent traceless, non-commuting elements, it generates $\mathfrak{su}(2)$ (standard Lie-generation criterion). Exponentiating yields a connected subgroup of U(2) whose commutator algebra is $\mathfrak{su}(2)$, i.e. SU(2) up to overall phase. Thus admissible controls act as effective SU(2) on S_x, giving (ii). (In the present framework the existence of at least two such independent compressed generators is ensured once the Twofold sector is non-abelian; equivalently, once the top-left block of the Fourfold

correlator is non-degenerate, which is the generic case discussed in the Twofold-vs-Fourfold analysis.)

Step 4 (On block-diagonalisable couplings and negligible back-reaction). Let the full local generator (drift + controls) decompose as

$$H = \begin{pmatrix} H_{S_x} & 0 \\ 0 & H_{S_x^\perp} \end{pmatrix} + \begin{pmatrix} 0 & K \\ K^\dagger & 0 \end{pmatrix} =: H_0 + \Delta, \qquad \|\Delta\| = \|K\| = \varepsilon.$$

Let $\mathcal{U}(t) := e^{-itH}$ be the propagator. By Duhamel's formula [381, 241, 287],

$$\mathcal{U}(t) - e^{-itH_0} = -i \int_0^t \mathcal{U}(t-s)\, \Delta\, e^{-isH_0}\, ds,$$

and, since H, H_0 are self-adjoint, $\|\mathcal{U}(\tau)\| = \|e^{-i\tau H_0}\| = 1$. Hence

$$\|(I-P)\,\mathcal{U}(t)\,P\| \;\le\; \int_0^t \|\Delta\|\, ds \;=\; \varepsilon t,$$

so leakage amplitude from S_x is $O(\varepsilon t)$ and probabilities $O((\varepsilon t)^2)$. In the regime "negligible over the control timescale" ($\varepsilon t \ll 1$), the action on S_x is well-approximated by $e^{-itH_{S_x}} \in \mathrm{U}(2)$, i.e. the effective SU(2) dynamics above.

Step 5 (Gauge/trivialisation independence). The constructions are independent of the choice of unitary frame and extend verbatim to h-orthonormal frames: replace $U(4)$ by the h-preserving group $G_h = \{g \mid g^\dagger h g = h\}$ and use metric-compatibility $\partial_\mu h - \mathcal{A}_\mu^\dagger h - h\mathcal{A}_\mu = 0$ to retain the covariant Leibniz rule; all equalities then hold with pairings $(c^\Phi)^\dagger h\, c^\Psi$ (cf. Remark 4.271).

This completes the proof. □

Context and links to earlier structure. The Twofold sector S_x is precisely the qubit-like "top-left block" inside the Fourfold correlator; when off-block mixings are negligible, ordinary qubit kinematics is recovered; when mixing with $\{p, s\}$ is appreciable, new (non-qubit) phenomena arise—exactly as stated in the surrounding text.

Why include this proof? It (a) makes explicit where the isometry, statistics-equivalence, and SU(2) control action come from in the bundle language; (b) isolates the approximation in a single norm bound; and (c) shows gauge-independence and the h-orthonormal generalisation are already baked in via the preceding lemma/remark on fibre pairings and metric-compatible connections.

Corollary 4.301 (Exact vs. Approximate Qubit Reduction)**.** *Retain the setting of Proposition 4.300 with $S_x = \mathrm{span}\{|\alpha_x\rangle, |\beta_x\rangle\}$ and orthogonal projector P onto S_x. Let the local generator (drift + controls) decompose as*

$$H \;=\; \underbrace{\begin{pmatrix} H_{S_x} & 0 \\ 0 & H_{S_x^\perp} \end{pmatrix}}_{=:H_0} + \underbrace{\begin{pmatrix} 0 & K \\ K^\dagger & 0 \end{pmatrix}}_{=:\Delta}, \qquad \|\Delta\| = \|K\| \le \varepsilon.$$

(a) Exact reduction ($\varepsilon = 0$). *If* $\Delta = 0$, *then for all* t,

$$\mathcal{U}(t) = e^{-itH} = e^{-itH_{S_x}} \oplus e^{-itH_{S_x^\perp}}, \quad \text{and} \quad P\,\mathcal{U}(t)\,P \;=\; e^{-itH_{S_x}} \in \mathrm{U}(2).$$

Thus the isometric embedding $U : \mathbb{C}^2 \to \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ *from Proposition 4.300 is an* exact *qubit equivalence: Born statistics and admissible controls coincide with those on the effective* SU(2) *dynamics on* S_x.

(b) Approximate reduction ($\varepsilon > 0$). *For* $\mathcal{U}(t) = e^{-itH}$ *the leakage from* S_x *into* $S_x^\perp$ *and the deviation of the compressed evolution from the ideal* $e^{-itH_{S_x}}$ *obey, for all* $t \geq 0$,

$$\left\|(I - P)\,\mathcal{U}(t)\,P\right\| \;\leq\; \varepsilon\, t, \qquad \left\|P\,\mathcal{U}(t)\,P \;-\; e^{-itH_{S_x}}\right\| \;\leq\; \varepsilon\, t.$$

In particular, for any unit vector $|\psi\rangle \in S_x$,

$$\|(I - P)\,\mathcal{U}(t)\,|\psi\rangle\,\|^2 \;\leq\; (\varepsilon t)^2,$$

so on timescales with $\varepsilon t \ll 1$ *the effective* SU(2) *description on* S_x *holds to first order in* εt.

Proof. For (a), $\Delta = 0$ makes H block-diagonal, yielding the direct-sum evolution and the exact identity $P\,\mathcal{U}(t)\,P = e^{-itH_{S_x}}$.

For (b), write $H = H_0 + \Delta$ and use Duhamel's formula

$$\mathcal{U}(t) - e^{-itH_0} = -i\int_0^t \mathcal{U}(t-s)\,\Delta\,e^{-isH_0}\,ds.$$

Since H and H_0 are self-adjoint, $\|\mathcal{U}(\tau)\| = \|e^{-i\tau H_0}\| = 1$; thus

$$\|\mathcal{U}(t) - e^{-itH_0}\| \;\leq\; \int_0^t \|\Delta\|\,ds \;=\; \varepsilon t.$$

Left- and right-multiplying by $I - P$ and P yields the leakage bound $\|(I - P)\,\mathcal{U}(t)\,P\| \leq \varepsilon t$. Moreover,

$$P\,\mathcal{U}(t)\,P - e^{-itH_{S_x}} = P\Big(\mathcal{U}(t) - e^{-itH_0}\Big)P + P\Big(e^{-itH_0} - e^{-itH_{S_x}} \oplus e^{-itH_{S_x^\perp}}\Big)P,$$

and the second term vanishes by block-diagonality of H_0, giving $\|P\,\mathcal{U}(t)\,P - e^{-itH_{S_x}}\| \leq \|\mathcal{U}(t) - e^{-itH_0}\| \leq \varepsilon t$, as stated. The probability bound follows immediately from the leakage estimate. □

Corollary 4.302 (Registers)**.** *Let* $x_1, \ldots, x_n$ *be* n *distinct PQS loci. For each* j *assume the hypotheses of Proposition 4.300: there exists a stabilised two-dimensional sector* $S_{x_j} = \mathrm{span}\{|\alpha_{x_j}\rangle, |\beta_{x_j}\rangle\} \subset \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_{x_j})$ *with isometric embedding* $U_j : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_{x_j})$, $U_j\,|0\rangle = |\alpha_{x_j}\rangle$, $U_j\,|1\rangle = |\beta_{x_j}\rangle$. *Assume further that cross–inter-modal correlator blocks between distinct fibres are perturbatively suppressed in the sense of Section 4.1.2, so that the global generator decomposes as*

$$H \;=\; \sum_{j=1}^{n} H^{(j)} \;+\; \sum_{i<j} H^{(ij)} \;+\; \Delta, \qquad \|\Delta\| \leq \varepsilon,$$

where $H^{(j)}$ acts locally on $\mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_{x_j})$, $H^{(ij)}$ is a controlled (switchable) two-fibre coupling, and Δ collects off-block terms.

Then the map

$$U^{(n)} \;:=\; U_1 \otimes \cdots \otimes U_n : (\mathbb{C}^2)^{\otimes n} \longrightarrow \bigotimes_{j=1}^{n} \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_{x_j})$$

is an isometric embedding with image $S_{x_1} \otimes \cdots \otimes S_{x_n}$, and:

(a) Exact reduction ($\varepsilon = 0$)

If $\Delta = 0$ and each compressed local algebra $P_j H^{(j)} P_j$ generates $\mathfrak{su}(2)$ on S_{x_j}, then the effective arena is exactly $(\mathbb{C}^2)^{\otimes n}$ under $U^{(n)}$, and any switchable two-site interaction with nontrivial compressed part $P_{ij} H^{(ij)} P_{ij} \notin \mathfrak{u}(2) \oplus \mathfrak{u}(2)$ ($P_{ij} = P_i \otimes P_j$) yields an entangling two-qubit gate on the (i, j) register. In particular, single-qubit $\mathrm{SU}(2)$ on each site together with any fixed entangling two-qubit gate forms a universal gate set on $(\mathbb{C}^2)^{\otimes n}$ [287].

(b) Approximate reduction ($\varepsilon > 0$)

Let $\mathcal{U}(t) = e^{-itH}$ and $P = \bigotimes_{j=1}^{n} P_j$ with P_j the orthogonal projector onto S_{x_j}. Then, for all $t \geq 0$,

$$\|(I - P)\,\mathcal{U}(t)\,P\| \;\leq\; \varepsilon\, t, \qquad \Big\| P\,\mathcal{U}(t)\,P - e^{-it\sum_j P_j H^{(j)} P_j - it\sum_{i<j} P_{ij} H^{(ij)} P_{ij}} \Big\| \;\leq\; \varepsilon\, t,$$

so leakage outside $S_{x_1} \otimes \cdots \otimes S_{x_n}$ is $O\big((\varepsilon t)^2\big)$ and the compressed dynamics approximates a unitary on $(\mathbb{C}^2)^{\otimes n}$ to first order in εt.

Proof. Isometry of $U^{(n)}$ is immediate from that of each U_j and the tensor structure. Part *(a)* follows from block-diagonality ($\Delta = 0$), the sitewise $\mathfrak{su}(2)$ generation (by Proposition 4.300), and the fact that a two-qubit unitary with generator whose compression is not a sum of one-body terms is entangling; universality with local SU(2) plus any entangling two-qubit gate is standard [287]. Part *(b)* is the multi-site version of the Duhamel estimate used in Corollary 4.301: write $H = H_0 + \Delta$ with $H_0 = \sum_j H^{(j)} + \sum_{i<j} H^{(ij)}$ block-diagonal on $S_{x_1} \otimes \cdots \otimes S_{x_n}$, apply

$$\mathcal{U}(t) - e^{-itH_0} = -i \int_0^t \mathcal{U}(t - s)\,\Delta\, e^{-isH_0}\, ds,$$

use $\|\mathcal{U}(\tau)\| = \|e^{-i\tau H_0}\| = 1$, and then left/right compress by P to obtain the stated bounds. □

Remark 4.303 (Twofold block as a limit of the Fourfold correlator)**.** The Twofold correlator $\hat{\mathbf{G}}_{(0,1)}(x, x')$ is the top-left 2×2 block of the full Fourfold matrix $\big[\hat{G}_{\Lambda}^{\alpha\beta}(x, x')\big]_{\alpha,\beta \in \{0,1,p,s\}}$. Negligible off-block terms reproduce conventional qubit kinematics; non-negligible mixing with $\{p, s\}$ drives strictly non-qubit phenomena.

The Qubit in IQR: Epistemic, Operational, and Geometric Synthesis

Epistemic status (abstract type vs. derived sector). In standard QM/QI the qubit is an *abstract type*—an isomorphism class of pairs $(\mathbb{C}^2, \langle\cdot,\cdot\rangle)$ with the Born rule [379, 287]. In the IQR framework, by contrast, the qubit is *derived*: it is the equivalence class (modulo SU(2) gauge) of isometric embeddings

$$U : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x), \qquad U\,|0\rangle = |\alpha_x\rangle\,, \quad U\,|1\rangle = |\beta_x\rangle\,,$$

when a dynamically protected Twofold sector $S_x := \mathrm{span}\{|\alpha_x\rangle\,, |\beta_x\rangle\}$ exists (Definition 4.273, Proposition 4.300, and Corollary 4.301).

Operational continuity (laboratory import). Laboratory qubits remain effective two-level carriers; the IQR construction supplies *deeper semantics*—why such sectors exist, how their inner products are *induced*, and when the reduction is valid. Standard practical concerns (decoherence, control, and fault-tolerance) retain their usual form in the effective regime [351, 380, 349].

Two narratives, contrasted.

(i) *Classical (axiomatic/postulatory) narrative.* One *postulates* a fixed two-dimensional complex Hilbert space $\mathbb{C}^2$ with its inner product, Born rule, and unitary controls; a pure qubit is any unit vector in $\mathbb{C}^2$ up to global phase, and composites are $(\mathbb{C}^2)^{\otimes n}$ [379, 287]. The dimension, metric, and control algebra are taken *as givens*.

(ii) *IQR (derivational) narrative.* One begins with the Fourfold Dialectic operator algebra at each PQS and the universal Holo-State. From these:

(a) the fibre inner product on each modal space is *induced* from the Fourfold Inter-Modal Correlator via the GNS procedure—hence the metric is *state-dependent*, not a background axiom (Section 4.6 and Definition 4.9);

(b) under explicit stability/decoupling hypotheses (block-diagonalisable couplings with negligible back-reaction) a two-dimensional sector $S_x \subset \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ is *selected*, and an isometric embedding $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$ is exhibited (Proposition 4.300);

(c) admissible local generators, compressed to S_x, *realise* the effective control algebra $\mathfrak{su}(2)$, yielding SU(2) dynamics; measurement statistics agree because $E \mapsto UEU^\dagger$ is a unital $*$-monomorphism preserving POVMs (Proposition 4.300);

(d) when off-block couplings are small but nonzero, Duhamel bounds *quantify* the approximation; exact/approximate regimes are recorded, and an n-site register $(\mathbb{C}^2)^{\otimes n}$ emerges when cross-correlators are perturbatively suppressed (Corollaries 4.301 and 4.302 and Section 4.1.2).

Geometry as expectation and the information–geometry link. The same state-dependence that induces inner products on modal fibres also determines vacuum geometry:

$$\bar{\Sigma}_{\mu\nu}(x) = \left\langle \Omega_\Psi \middle| \hat{\Sigma}_{\mu\nu}(x) \middle| \Omega_\Psi \right\rangle,$$

so the relocation of the qubit (as a reduced Twofold sector of a Fourfold fibre) and the emergence of spacetime geometry share a single operator-theoretic mechanism: both are *expectation-value* effects of one Holo-State over a common algebraic substrate (Definition 5.26).

Bottom line. The treatise does not *supplant* the qubit; it *grounds and generalises* it. In correlator-sparse regimes the Twofold block reduces to conventional qubit kinematics; beyond that, parasymmetric/holosymmetric mixing carries one *beyond* the qubit paradigm. The abstract qubit survives as an effective type and a useful instrument, now situated within a background-free, correlator-generated modal geometry [241, 381, 287].

4.7.5 The Abstract Qubit (Wordwise Relocation)

From abstract bits to wordwise modal structure. In the endogenous calculus, an "elementary quantum of information'' is not a fixed $\mathbb{C}^2$ but a *protected two-letter subalphabet* inside a word–rotated modal fibre. The fibre metric is induced (not postulated) from the Fourfold correlator, while device words $\mathbf{W}$ select operational frames and channels (Definitions 4.255 and 4.257 and Proposition 4.258).

Definition 4.304 (Wordwise twofold sector at a PQS)**.** Fix $x \in \mathcal{X}_q$, a unitary device word $\mathbf{W}$, and control χ. Let $\mathcal{B}_x^{[\mathbf{W},\chi]} = \{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}, |p\rangle_x^{[\mathbf{W},\chi]}, |s\rangle_x^{[\mathbf{W},\chi]}\}$ be the word–rotated orthonormal frame (Definition 4.257 and Proposition 4.258). Define the *wordwise twofold sector*

$$S_x^{[\mathbf{W}]} := \operatorname{span}\Big\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\Big\} \subset \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}.$$

The parasymmetric/holosymmetric complement is $S_{x,\perp}^{[\mathbf{W}]} := \operatorname{span}\Big\{|p\rangle_x^{[\mathbf{W},\chi]}, |s\rangle_x^{[\mathbf{W},\chi]}\Big\}$.

Definition 4.305 (Wordwise qubit realisation)**.** The *wordwise abstract qubit at x* is an isometric embedding $U^{[\mathbf{W}]} : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ defined by

$$U^{[\mathbf{W}]}|0\rangle = |0\rangle_x^{[\mathbf{W},\chi]}, \qquad U^{[\mathbf{W}]}|1\rangle = |1\rangle_x^{[\mathbf{W},\chi]},$$

with the induced fibre inner product from the Fourfold correlator (Section 4.6 and eq. (4.85)). Thus any $|\psi\rangle \in \mathbb{C}^2$ is represented in the fibre as $U^{[\mathbf{W}]}|\psi\rangle \in S_x^{[\mathbf{W}]}$ with the same Born valuations.

Proposition 4.306 (Wordwise qubit reduction and control)**.** *Assume the word–evaluated off–diagonal blocks that couple $S_x^{[\mathbf{W}]}$ to $S_{x,\perp}^{[\mathbf{W}]}$ are (exactly) zero or (approximately) small in operator norm, as diagnosed by $\hat{\mathbf{G}}_\Lambda^{[\mathbf{W}]}(x,x')$ (Proposition 4.262). Then:*

(i) (Isometry & statistics). *$U^{[\mathbf{W}]}$ is an isometric embedding onto $S_x^{[\mathbf{W}]}$, and $E \mapsto \widetilde{E} := U^{[\mathbf{W}]} E \big(U^{[\mathbf{W}]}\big)^\dagger$ preserves POVMs and Born probabilities in the fibre metric.*

(ii) (Effective SU(2) controls). *If the admissible local generators at x, compressed to $S_x^{[\mathbf{W}]}$, contain two independent traceless, noncommuting elements, they generate $\mathfrak{su}(2)$ on $S_x^{[\mathbf{W}]}$; hence admissible controls act as effective* SU(2) *on the wordwise qubit.*

(iii) (Leakage bounds). *If the residual off–block couplings have norm ε, then for the propagator $\mathcal{U}(t)$ generated by the full local Hamiltonian,*

$$\left\|(I - P^{[\mathbf{W}]})\,\mathcal{U}(t)\,P^{[\mathbf{W}]}\right\| \;\le\; \varepsilon\, t, \qquad P^{[\mathbf{W}]} := \text{orthogonal projector onto } S_x^{[\mathbf{W}]},$$

so leakage probability is $O((\varepsilon t)^2)$ (Duhamel estimate; cf. the exogenous Corollary 4.301).

Remark 4.307 (Role of compliance vector)**.** Operational deviations are controlled by the holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178): Δ bounds visibility/lensing drifts, η fixes two–step ps/sp amplitudes, and ζ controls diagonal pinching stability (Proposition 4.181, Lemma 4.180, and Remark 4.182). In particular, small η and ζ suppress mixing and misalignment of the twofold sector under wordwise transport, keeping the effective qubit clean.

Corollary 4.308 (Wordwise qubit registers across loci)**.** *Let $x_1, \dots, x_n$ be distinct PQS loci, each with a protected twofold sector $S_{x_j}^{[\mathbf{W}_j]}$ and embedding $U_j^{[\mathbf{W}_j]}$. Define $U^{(n)} := U_1^{[\mathbf{W}_1]} \otimes \cdots \otimes U_n^{[\mathbf{W}_n]}$. If cross–fibre off–block terms are perturbatively suppressed (Section 4.1.2 and Proposition 4.262), then $U^{(n)}$ is an isometry*

$$U^{(n)} : \; (\mathbb{C}^2)^{\otimes n} \;\hookrightarrow\; S_{x_1}^{[\mathbf{W}_1]} \otimes \cdots \otimes S_{x_n}^{[\mathbf{W}_n]},$$

and the compressed multi–site dynamics approximates a unitary on $(\mathbb{C}^2)^{\otimes n}$ with error $O(\varepsilon t)$ as in Corollary 4.302.

Remark 4.309 (Twofold poles inside a genuinely Fourfold fibre (wordwise))**.** In the wordwise frame, $|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}$ are the dyadic poles *within* a genuinely Fourfold modality; $|p\rangle_x^{[\mathbf{W},\chi]}$, $|s\rangle_x^{[\mathbf{W},\chi]}$ are independent rays (not twofold superpositions) (Proposition 4.281 and Remark 4.286). The abstract qubit is therefore a *derived* two-letter sector—stable when off–block words/channels are small—rather than a background postulate.

Remark 4.310 (Gauge and word choice)**.** Changing the endpoint gauge or replacing $\mathbf{W}$ by $\mathbf{W}'$ conjugates the presentation by a unitary on the fibre (Propositions 4.260 and 4.284 and Definition 4.259); the isometry class of the qubit sector and its Born statistics are unaffected.

Bottom line (endogenous lens). The "qubit'' becomes a *state– and device–relative* twofold word sector $S_x^{[\mathbf{W}]} \subset \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ whose existence and quality are *diagnosed and bounded* by word–evaluated channels and the compliance vector. When off–block couplings are negligible, standard SU(2) qubit kinematics is recovered; when mixing with $\{p, s\}$ is appreciable, the endogenous calculus predicts departures from the qubit paradigm and locates their operational signatures.

In the endogenous "alphabets & words'' view, a qubit is not postulated as a fixed $\mathbb{C}^2$ but recovered as a *protected two-letter sector* inside a word–rotated modal fibre. A unitary

device word $\mathbf{W}$ selects an operational frame $\mathcal{B}_x^{[\mathbf{W},\chi]}$ on the fibre $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ (Definition 4.257 and Proposition 4.258), whose inner product is *induced* from the Fourfold correlator (Section 4.6 and eq. (4.85)). The wordwise twofold sector $S_x^{[\mathbf{W}]}$ and the isometric embedding $U^{[\mathbf{W}]} : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ formalise the "abstract qubit'' as a derived subalphabet with inherited Born statistics (Definitions 4.304 and 4.305). Independence of the parasymmetric/holosymmetric directions is explicit—$|p\rangle, |s\rangle$ are not twofold superpositions—so the dyad $(0, 1)$ lives inside a genuinely Fourfold fibre (Proposition 4.281 and Remark 4.286).

Control and robustness become operational statements. Compressing admissible generators to $S_x^{[\mathbf{W}]}$ yields $\mathfrak{su}(2)$ whenever two traceless noncommuting compressed elements exist, giving effective single–qubit dynamics (Proposition 4.306). Departures from the ideal are *quantified*: word–evaluated off–block couplings bound mixing (Proposition 4.262), while the holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ controls visibility/lensing drifts, two–step *ps*/*sp* amplitudes, and diagonal pinching stability (Definition 4.178, Proposition 4.181, Lemma 4.180, and Remark 4.182). Thus the regime where the qubit picture holds—and how it fails—is specified by measurable inequalities rather than by assumption.

Geometry completes the picture. The modal connection $\mathcal{A}$ and its holonomy are read out in the s–channel via the wordwise loop operator $\hat{H}_\ell^{(s)[\mathbf{W}]}(x)$ and its expectation $h_\ell^{(s)[\mathbf{W}]}(x)$ (Section 4.7.3 and eqs. (4.122) and (4.123)). Flat, simply connected regions trivialise the loop signal, while curvature or topology produce robust phases (Proposition 4.295). In this way, the qubit emerges as a state–and device–relative code sector whose metric, controls, error modes, and geometric phases are all generated and certified by the same wordwise, Fourfold correlator machinery.

4.7.6 The Holomodal Quantum Computer

Read "quantum computer'' in the broad, model–independent sense of a controllable physical process implementing algorithmic transformations on a state space. In this setting the IQR framework both preserves today's qubit computing and *enlarges* the design space in principled ways. The qubit reappears only as a *dynamically protected Twofold sector* inside a genuinely Fourfold modal fibre; concretely, as a *wordwise* two–letter subalphabet $S_x^{[\mathbf{W}]} \subset \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ selected by unitary device words and certified by word–evaluated channels (Definitions 4.255, 4.257, 4.304 and 4.305 and Proposition 4.258). When off–block couplings are negligible, ordinary qubit kinematics and gate sets are recovered (Qubit Reduction and Registers; Proposition 4.300 and Corollaries 4.301 and 4.302); in the endogenous picture this is the regime where $\{0, 1\}$ remains effectively closed under admissible controls while $\{p, s\}$ acts as a quiet complement (Propositions 4.262 and 4.281).

New Avenues (Schematic)

1. *Geometry–aware control.* The fibre metric and even the effective background geometry are *expectation–value* objects induced by the Holo–State, not fixed backdrops (Sections 4.6 and 4.7.4 and eq. (4.85)). This turns the arena into a *programmable resource*: algorithms can co–design dynamics with induced information–geometry, e.g. shaping correlators to alter effective locality or to pull up long–range holosymmetric entanglers on demand. Holonomy in the s–channel becomes a native geometric observable and

control knob (wordwise loop operator and signal; Section 4.7.3, eqs. (4.122) and (4.123), and Proposition 4.295).

2. *Modal augmentation beyond qubits.* Parasymmetric and holosymmetric modes are *independent* directions of the Fourfold, not superpositions within a dyad (Proposition 4.281 and Section 1.2.7). Controlled mixing with $\{p, s\}$ therefore yields strictly non–qubit primitives—drives, measurements, dissipative gadgets—operating natively in the Fourfold. The qubit model is recovered when those mixings are suppressed; otherwise, Hadamard–compatible words and channels give structured access to the additional modal resources (Corollary 4.225 and Definition 4.255).

3. *Register formation over PQS networks.* When cross–fibre correlators between selected loci are perturbatively sparse, an n–site *effective* arena $(\mathbb{C}^2)^{\otimes n}$ emerges with controlled inter–modal couplings yielding entangling two–site gates (Registers; Section 4.1.2 and Corollary 4.302). This ties scalable digital architectures directly to correlator sparsity and transport stability criteria (Definition 4.248 and Corollary 4.251).

The relocation does not merely *reinterpret* qubits; it adds programmable *correlator geometry* and genuinely *Fourfold* controls. Precision comes from inequalities: small off–block words/channels and the holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ bound visibility/lensing drift, two–step *ps*/*sp* amplitudes, and diagonal pinching errors (Definition 4.178 and Proposition 4.181). Duhamel–type estimates then quantify leakage when mixings are weak but nonzero, giving principled tolerances for *hybrid* processors that exploit gentle $\{0, 1\} \leftrightarrow \{p, s\}$ couplings while retaining qubit–level programmability on protected Twofold sectors (Corollary 4.301 and Proposition 4.306).

Definition (Holomodal Quantum Computer). A holomodal quantum computer comprises: (i) a modal Hilbert bundle $\mathscr{H}_{\mathrm{mod}} \to \mathcal{X}_q$ with fibre metric *induced* by the Fourfold correlator (Section 4.6 and Definition 4.9); (ii) an admissible control algebra generated by Fourfold dialectic operators together with a metric–compatible connection acting on fibres, obeying the covariant Leibniz rule (Section 1.2.7, Lemma 4.270, and Definition 4.248); and (iii) fibre effect algebras (POVMs) including parasymmetric/holosymmetric channels, with dynamics and readout defined by expectations in the state–dependent arena (Section 4.7.4).

How it relates to qubit computing.

1. *Contains* the qubit model as a limit: when a Twofold sector is dynamically protected and cross–couplings are block–diagonalisable, the Qubit Reduction yields an isometric embedding $U : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}(\mathfrak{B}_x)$; multi–site registers arise under correlator sparsity (Proposition 4.300 and Corollaries 4.301 and 4.302).

2. *Extends* it by natively using the full Fourfold: operations act directly on $\{|0\rangle, |1\rangle, |p\rangle, |s\rangle\}$, with controlled $\{p, s\}$ mixing enabling gates and measurements with no qubit analogue (Section 1.2.7 and Proposition 4.262).

3. *Programs the arena itself:* since the fibre metric and vacuum geometry are expectation–value objects, correlator engineering becomes a computational resource—co–designing dynamics with induced information–geometry and reading global structure via wordwise holonomy (Sections 4.7.3 and 4.7.4).

What to call it (taxonomically). A **holomodal (Fourfold) quantum computer**: a background–free, operator–algebraic model in which "qubits" appear as *derived* Twofold sectors when conditions warrant, yet computation can proceed in the full Fourfold with correlator–programmable resources. Qubit circuits are recovered in correlator–sparse regimes; beyond them, a broader gate/measurement set—tied to parasymmetry/holosymmetry, to wordwise transport, and to state–dependent geometry—becomes available within the same formalism (Definition 4.304, Propositions 4.181 and 4.306, Corollary 4.308, and Section 4.7.3).

4.8 The Intrinsic Coherence of the PQS Continuum

Within the Interdependent Quantum Reality (IQR) framework, *entanglement* is elevated from a contingent, subsystem–relative feature to a *structural property* of the Primordial Quantum Singularity (PQS) continuum itself. Rather than beginning with an *a priori* product Hilbert space and declaring non-separable vectors to be "entangled," IQR posits an *operator-theoretic* universality: the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ globally conditions the algebra of Fourfold modes so that relational observables, metrics, and coherences *emerge between* PQS loci $\mathfrak{B}_x, \mathfrak{B}_{x'}$ (Definition 1.27). In this sense, universal entanglement is ontological: it is the default coherence of the $\hat{\Omega}$–Continuum, from which phenomenological (subsystem) entanglement is recovered as a special, effective limit (cf. table 4.1). The underlying motivation follows the IQR dictum that observable structure (distance, time, geometry) crystallises *relationally* across distinct PQS loci rather than *within* any single locus.

4.8.1 The Operator-Theoretic Nature of Ontological PQS Entanglement

The inherent entanglement of primordial quantum singularities (Definition 1.25) and of the $\hat{\Omega}$–Continuum they constitute is exhibited by the following intrinsic properties.

1. Bilocal Fourfold coherence via $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$. The *Fourfold Inter-Modal Correlator* (Definition 4.9) furnishes a nonlocal, operator-valued relation between distinct PQS loci:

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] := \sum_{\alpha,\beta\in\{0,1,p,s\}} (c_{1\alpha})^* c_{2\beta} \left(\hat{\mathcal{F}}_\alpha(x)^\dagger \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')\right), \tag{4.131}$$

where $\mathcal{U}(x \leftarrow x'; \gamma)$ is the parallel transporter that aligns local frames along a path $\gamma \subset \mathcal{X}_q$. The Holo-State expectation

$$\left\langle \mathring{\mathbf{\Psi}} \middle| \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \middle| \mathring{\mathbf{\Psi}} \right\rangle$$

quantifies an *algebraic overlap* (an "entanglement amplitude") between the modal data at $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$, independent of any classical embedding. This bilocal kernel is the primary manifestation of universal entanglement in the continuum.

2. Globally conditioned local structure (emergent fibre metric). The same correlator governs the *local* inner product on each modal fibre by the coincident-limit prescription

$$\langle \psi_1, \psi_2 \rangle_x := \lim_{x' \to x} \Big\langle \mathring{\mathbf{\Psi}} \,\Big|\, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] \,\Big|\, \mathring{\mathbf{\Psi}} \Big\rangle,$$

so that the fibre metric is *induced* from Fourfold expectations rather than postulated (Section 4.6). Positivity of the Holo-State functional ensures a well-defined Hilbert fibre after quotienting the null space and completing; thus correlator expectations *forge* the metric on which Fourfold modes are read.

3. Gauge-covariant comparison across the continuum. Relational claims between x' and x are made in a frame-consistent manner by the unitary transporter $\mathcal{U}(x \leftarrow x'; \gamma) \in \mathrm{U}(\mathcal{H}_{\mathrm{em}})$, ensuring that channel operators $\hat{G}_\Lambda^{\alpha\beta}(x, x') = \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$ are gauge-covariant. This underwrites the observer-independence of the entanglement amplitude defined above (cf. Lemma 4.270).

4. The continuum's triadic axes of relational geometry and time. Universal entanglement is not isolated from geometry; it is one axis of a triad of intrinsic relational *distances* on $\mathcal{X}_q$,

$$\vec{d}(x, x') = \Big(d_{\mathrm{corr}},\, d_{\mathrm{vac}},\, d_{\mathrm{spec}}\Big),$$

with the corresponding *axis-specific temporal parameters*

$$\vec{t}(x, x') = \Big(t_{\mathrm{corr}},\, t_{\mathrm{vac}},\, t_{\mathrm{spec}}\Big),$$

introduced as the *entanglement phase time*, *vacuum response time*, and *spectral shear time*, respectively (see Section 4.12). The three axes are *functionally orthogonal*, arising from algebraically distinct operator features of $\hat{G}_\Lambda$ and its spectral commutator: bilocal/off–diagonal structure for d_{corr} (paired with t_{corr}), diagonal/coincident variation for d_{vac} (paired with t_{vac}), and the commutator with the spectral generator $\hat{D}$ for d_{spec} (paired with t_{spec}). See Section 4.11.3 for the formal construction of the *Relational Distinguishability Fiber* and the assembly of these axes; the specialisation to *emergent proper* distances and times—the classical limit of ordinary experiences—is developed later in Section 5.3.8.

5. Ontological versus phenomenological entanglement. The foregoing properties define an *ontological* layer of entanglement—the default operator-level coherence of the $\hat{\Omega}$–Continuum—distinct from *phenomenological* (subsystem) entanglement in fixed tensor-product arenas. The latter reappears when the Fourfold correlator's Twofold block decouples (qubit reduction) and when cross-correlators across chosen fibres are perturbatively suppressed, yielding the usual $(\mathbb{C}^2)^{\otimes n}$ registers and their entangling gates (cf. Proposition 4.300 and Corollary 4.302). In this regime, the IQR account reduces to familiar quantum-information kinematics and dynamics.

Proposition 4.311 (Operational manifestations of ontological entanglement)**.** *In the IQR framework, the operator–theoretic (ontological) entanglement defined by the Holo-State* $|\mathring{\mathbf{\Psi}}\rangle$

and the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda$ (Definitions 1.27 and 4.9) is a foundational *feature of the $\hat{\Omega}$–Continuum. It is generally not directly witnessable by finite-subsystem Bell tests, but it admits the following gauge-covariant* operational footprints*:*

(i) Expectation-induced geometry.
The chronogeometric tensor $\bar{\Sigma}_{\mu\nu}(x) = \langle\Omega_\Psi|\hat{\Sigma}_{\mu\nu}(x)|\Omega_\Psi\rangle$ (Definition 5.26) encodes global correlational structure; nontrivial dependence of $\bar{\Sigma}$ on the Holo-State implements geometric effects of ontological entanglement.

(ii) Emergent fibre metrics.
The local inner product on each modal fibre is induced *via the coincident-limit of $\hat{G}_\Lambda$ expectations (Section 4.6), so the very existence and positivity of the fibre Hilbert spaces reflect the continuum's entangled substrate.*

(iii) Holosymmetric interferometry.
Visibility functionals in holosymmetric interference experiments (e.g., Section 3.1 and Section 3.1.4) are Holo-State expectations of bilocal operators built from $\hat{G}_\Lambda$; their nontrivial values witness globally maintained operator histories rather than factorised subsystem coherence.

(iv) Effective two-level sectors and registers.
Stability of Twofold sectors and their inter-fibre registers—captured by the qubit reduction and registers results (Proposition 4.300 and Corollary 4.302)—are controlled by block structure and sparsity of $\hat{G}_\Lambda$; persistence of effective SU(2) *dynamics is thereby an operational signature of universal entanglement in the sparse-coupling regime.*

Justification (sketch). (i) follows immediately from the definition of $\bar{\Sigma}$ as a Holo-State expectation of geometric operators, whose inputs are conditioned by the same algebraic substrate governed by $\hat{G}_\Lambda$ (Definition 5.26). (ii) is the coincident-limit construction of the modal inner product from $\hat{G}_\Lambda$ with positivity and completion ensuring a genuine Hilbert fibre (Section 4.6). (iii) uses that holosymmetric visibility is defined as a gauge-covariant functional of bilocal Fourfold operators, hence sensitive to nonlocal coherence rather than factorised subsystems (Sections 3.1 and 3.1.4). (iv) is a direct consequence of the block-diagonalisable regime in which Twofold sectors are dynamically protected and cross-correlators are perturbatively suppressed, yielding effective SU(2) controls and entangling inter-fibre gates (Proposition 4.300 and Corollary 4.302). □

Ontological Emergence: Dependency Chain

The definitional dependencies can be summarised succinctly as

$$|\mathring{\boldsymbol{\Psi}}\rangle \xrightarrow[\text{Definition 4.9}]{\text{induces}} \hat{G}_\Lambda \xrightarrow[\text{Section 4.6}]{\text{coincident limit}} \langle\cdot,\cdot\rangle_x \xrightarrow[\text{Definition 5.26}]{\text{geometric operators}} \hat{\Sigma}_{\mu\nu}(x) \xrightarrow{\langle\cdot\rangle} \bar{\Sigma}_{\mu\nu}(x).$$

This emphasises that the emergent fibre metric and the expectation-level geometry are both grounded in Holo-State expectations of Fourfold operator structure, without implying a dynamical cascade.

Structural / Ontological PQS Entanglement	**Phenomenological / Conventional Entanglement**
An intrinsic property of the PQS continuum (Definition 4.617) conditioned by the Quantum Holo-State $\|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27); it expresses global coherence of the $\hat{\Omega}$–Continuum.	A property of particular states within an *emergent* (often approximately factorisable) subsystem arena, e.g. registers $(\mathbb{C}^2)^{\otimes n}$ obtained in the sparse–coupling regime (Corollary 4.302).
Arises from nonlocal Fourfold operator relations (the inter–modal correlator $\hat{G}_\Lambda$) and *induces* local structures via Holo-State expectations—e.g. the modal fibre inner product by the coincident limit (Definition 4.9 and Section 4.6).	Characterised by non-separability of a state with respect to a chosen tensor product; canonical examples include Bell states and entangling two-qubit gates in the register model [287].
No PQS or local modal space is fundamental in isolation: fibre metrics and comparisons are *relational* (parallel transport $\mathcal{U}(x \leftarrow x'; \gamma)$; gauge-covariant pairings) and depend on the same correlator geometry (Lemma 4.270).	Subsystems are *defined* with respect to a fixed or effective factorisation; correlations are then assessed relative to that choice (entangled vs. product) within the given background Hilbert structure.
The qubit appears as a *derived*, dynamically protected Twofold sector when off-block couplings are block-diagonalisable; statistics and controls match an effective SU(2) (Proposition 4.300).	Qubits are *postulated* as $(\mathbb{C}^2, \langle\cdot,\cdot\rangle)$ objects with prescribed controls and measurements; universality follows from local SU(2) plus any entangling two-qubit gate [287].
Suppression (not literal absence) of specific correlator blocks yields classical-like product structure and trivialised mixing in the corresponding sectors; exact vanishing is a singular/ideal limit. In this regime, phenomenological entanglement notions are recovered (Corollaries 4.301 and 4.302).	Absence of entanglement simply means a product state in the chosen factorisation; it does not, by itself, constrain geometric or fibre-inducing structures.

Table 4.1: Distinction between *ontological* entanglement (a global, correlator-driven property of the PQS continuum) and *phenomenological* entanglement (non-separability relative to a chosen subsystem factorisation).

The Nature of Ontological Entanglement: From a Unified Whole to Apparent Parts

A foundational principle of the IQR framework is that the universe is a single, indivisible quantum system, intrinsically entangled by the Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ acting on the Fourfold algebra at every PQS locus (Definitions 1.27 and 4.9). This raises a natural question: if reality is

globally entangled, why do we *experience* a world of apparently separate, classical objects governed by local laws?

Answer in IQR. Separation is not fundamental but *emergent*. What looks like the "failure" of entanglement is precisely the theory's mechanism for the appearance of classicality: when specific correlator structures are suppressed or effectively factorised, the relational substrate yields autonomous, approximately local sectors. The following conditions formalise this emergence.

Proposition 4.312 (Apparent separability: three mechanisms)**.** *Let $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ be the Fourfold Inter-Modal Correlator and $\mathcal{U}(x \leftarrow x'; \gamma)$ the parallel transporter (Definition 4.9 and Lemma 4.270). Then:*

(a) Structural disconnection (vanishing bilocal coherence). *If for all test coefficients $c_{1\alpha}, c_{2\beta}$ and all admissible paths γ one has*

$$\left\langle \mathring{\mathbf{\Psi}} \middle| \hat{\mathcal{F}}_\alpha(x)^\dagger \, \mathcal{U}(x \leftarrow x'; \gamma) \, \hat{\mathcal{F}}_\beta(x') \middle| \mathring{\mathbf{\Psi}} \right\rangle = 0,$$

then no gauge-covariant bilocal coherence is present between $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$. Operationally this is a superselection*–type separation of sectors (a correlator-null block), i.e. an ontological decoupling at the operator level.*

(b) Effective factorisation (approximate product structure). *Suppose there is an emergent bipartition of the observable algebra into commuting subalgebras $\mathcal{A}_x$ and $\mathcal{A}_{x'}$ (relative to a chosen frame) and that the Holo-State admits a product approximation $\rho \approx \rho_x \otimes \rho_{x'}$ with trace distance $\|\rho - \rho_x \otimes \rho_{x'}\|_1 \leq \varepsilon$. Then for all $A \in \mathcal{A}_x$, $B \in \mathcal{A}_{x'}$,*

$$\left| \operatorname{Tr}[(\rho - \rho_x \otimes \rho_{x'}) \, A \otimes B] \right| \;\leq\; \varepsilon \, \|A\| \, \|B\|,$$

so bilocal correlators factorise up to $O(\varepsilon)$. This "for-all-practical-purposes" separability explains autonomous subsystems without contradicting global ontological entanglement.

(c) Decoherence (suppression of off-diagonal Fourfold blocks). *Under admissible open dynamics with generator $\mathcal{L}$ (e.g. a Lindbladian), off-diagonal blocks of the correlator decay, $\|(\hat{G}_\Lambda)_{\mathit{off}}(t)\| \leq e^{-\Gamma t} \|(\hat{G}_\Lambda)_{\mathit{off}}(0)\|$ for some rate $\Gamma > 0$, driving an* effective localisation *of correlations (cf. the emergence of classicality by environment-induced superselection [380]). In this regime the bilocal kernel behaves approximately local, and qubit/register kinematics reappear when the Twofold block is dynamically protected (Proposition 4.300 and Corollary 4.302).*

Justification (sketch). (a) is immediate from the definition of the bilocal channels and gauge-covariant transport (Definition 4.9 and Lemma 4.270). (b) follows from the Hölder–von Neumann inequality $|\operatorname{Tr}(XY)| \leq \|X\|_1 \|Y\|$ applied to $X = \rho - \rho_x \otimes \rho_{x'}$ and $Y = A \otimes B$. (c) is the standard decoherence mechanism: completely positive contractive dynamics suppress coherence between pointer sectors, here realised as decay of off-diagonal Fourfold blocks [380]. □

Operational footprints (global, not few-body tests). Ontological entanglement is *operator-theoretic*, not primarily a property of pre-given tensor factors. Its empirical content appears in:

- *Expectation-induced geometry:* the chronogeometric tensor $\bar{\Sigma}_{\mu\nu}(x) = \langle\Omega_\Psi|\hat{\Sigma}_{\mu\nu}(x)|\Omega_\Psi\rangle$ encodes correlator geometry (Definition 5.26).
- *Emergent inner products:* fibre metrics arise from coincident-limit expectations of $\hat{G}_\Lambda$ (Section 4.6).
- *Holosymmetric interferometry:* visibility functionals are Holo-State expectations of bilocal operators (cf. Sections 3.1 and 3.1.4).
- *Protected Twofold sectors and registers:* persistence of effective SU(2) dynamics and controllable entanglers in sparse-coupling regimes (Proposition 4.300 and Corollary 4.302).

Synthesis. In IQR the $\hat{\Omega}$–Continuum is *intrinsically entangled*. This is not a contingent feature of some specially prepared states but the *same* operator data that (i) *induce* modal fibre metrics and (ii) *determine* vacuum geometry via $\hat{\Sigma}_{\mu\nu}$. Apparent separations arise precisely under the mechanisms of Proposition 4.312, and in those regimes the familiar qubit/register formalism is recovered as an effective description.

4.8.2 Factorizability of the Quantum Holo-State and the Necessity of Ontological Entanglement

The Quantum Holo-State $|\overset{\circ}{\mathbf{\Psi}}\rangle$ (Definition 1.27) is the structural keystone of the IQR framework: it conditions the Fourfold operator algebra at each Primordial Quantum Singularity (PQS) (Definition 1.25) and, through its expectations, *induces* both local fibre metrics and expectation-level geometry. Clarifying what would follow *if* $|\overset{\circ}{\mathbf{\Psi}}\rangle$ were factorizable—and why, in IQR, it cannot be—is therefore essential.

I. What genuine factorization would entail

Consider a bipartition of the $\hat{\Omega}$–Continuum into sectors $\mathcal{X}_A$ and $\mathcal{X}_B$, with corresponding (frame-relative) commuting subalgebras $\mathcal{A}_A$ and $\mathcal{A}_B$. Suppose that

$$|\overset{\circ}{\mathbf{\Psi}}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle, \qquad \omega^{\overset{\circ}{\mathbf{\Psi}}} = \omega^A \otimes \omega^B,$$

i.e. the universal state and its expectation functional factorize across the partition.

(1) Collapse of nonlocal Fourfold channels. Let $x \in \mathcal{X}_A$ and $x' \in \mathcal{X}_B$. For any test coefficients $c_{1\alpha}, c_{2\beta}$ and admissible path γ, the bilocal Fourfold channel (Definition 4.9)

$$\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2] = \sum_{\alpha,\beta} (c_{1\alpha})^* c_{2\beta}\, \hat{\mathcal{F}}_\alpha^\dagger(x)\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}_\beta(x')$$

satisfies

$$\Big\langle \mathring{\mathbf{\Psi}}\Big|\hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2]\Big|\mathring{\mathbf{\Psi}}\Big\rangle = \omega^A\Big(\hat{\mathcal{F}}_\alpha^\dagger(x)\Big)\,\omega^B\Big(\mathcal{U}\,\hat{\mathcal{F}}_\beta(x')\Big),$$

which vanishes for generic gauge choices and mode content unless the transporter $\mathcal{U}$ and the operators reduce to purely local (diagonal) contributions. Operationally, cross-sector bilocal coherence is null: the correlator block is effectively zero.

(2) Block-diagonal emergent inner products. By the coincident-limit construction of the fibre inner product (Section 4.6, cf. eq. (4.6)), vanishing cross-sector expectations force the modal pairing to become block-diagonal with respect to the partition. Hence inter-sector comparisons are ill-defined, and the Hilbert bundle decouples across $\mathcal{X}_A \sqcup \mathcal{X}_B$.

(3) Entanglement entropy across the cut vanishes. Writing $\rho_A = \mathrm{Tr}_B|\mathring{\mathbf{\Psi}}\rangle\langle\mathring{\mathbf{\Psi}}| = |\psi_A\rangle\langle\psi_A|$ gives $S(\rho_A) = 0$. Conventional (subsystem) entanglement across $\mathcal{X}_A \leftrightarrow \mathcal{X}_B$ is absent, mirroring the collapse of Fourfold bilocal structure.

(4) Geometric and temporal fragmentation in $\mathcal{X}_q$. Since expectation-level geometry is induced from Holo-State expectations (cf. $\bar{\Sigma}_{\mu\nu}$ in Definition 5.26), cross-sector components of $\bar{g}_{\mu\nu}$ (Definition 5.10) and of the temporal tensor are forced to vanish. Consequences include:

- a block-diagonal (possibly degenerate) $\bar{g}_{\mu\nu}$ across the cut, prohibiting coherent geometric relations between $\mathcal{X}_A$ and $\mathcal{X}_B$;
- loss or ill-definition of emergent temporal displacements across the cut (no well-defined axis-specific $t_{\mathrm{corr}}, t_{\mathrm{vac}}, t_{\mathrm{spec}}$ for cross-sector paths; cf. Section 4.12);
- fragmentation of causal structure (Section 5.4) into operator-disconnected components.

(5) Physical meaning: a classical/decohered limit. For $A \in \mathcal{A}_A$, $B \in \mathcal{A}_B$, $\langle\hat{\mathcal{O}}_A\hat{\mathcal{O}}_B\rangle = \langle\hat{\mathcal{O}}_A\rangle\langle\hat{\mathcal{O}}_B\rangle$, and holosymmetric interference between histories supported on disjoint sectors is suppressed (cf. Section 2.4). The partition behaves as independent classical-like domains. In summary,

> Exact factorization ⇒ vanishing cross–sector Fourfold channels
> ⇒ block–diagonal inner products & fragmented geometry.

Approximate factorization (FAPP). If $\rho \approx \rho_A \otimes \rho_B$ with trace distance $\|\rho - \rho_A \otimes \rho_B\|_1 \le \varepsilon$, then $|\,\mathrm{Tr}[(\rho - \rho_A \otimes \rho_B)A \otimes B]| \le \varepsilon\|A\|\,\|B\|$. Correlators factorize up to $O(\varepsilon)$, explaining *emergent* autonomy of subsystems without contradicting global ontological entanglement.

II. A theorematic constraint: $|\mathring{\mathbf{\Psi}}\rangle$ cannot factorize in IQR

Theorem 4.313 (Necessity of non-factorizability)**.** *Within the IQR framework, any genuine factorization of the Quantum Holo-State across a nontrivial partition of the $\hat{\Omega}$–Continuum is*

incompatible with the existence of (i) nontrivial gauge-covariant bilocal Fourfold channels, (ii) a coherent, nondegenerate fibre inner product at all loci, and (iii) a connected expectation-level chronogeometry. Hence $|\mathring{\mathbf{\Psi}}\rangle$ *is necessarily non-factorizable.*

Proof sketch. (i) By Definition 4.9 and gauge-covariant transport (Lemma 4.270), factorization forces the expectation of any cross-sector bilocal channel to split and, generically, to vanish, annihilating nonlocal coherence.

(ii) The local fibre pairing is defined by the coincident limit of Holo-State expectations of $\hat{G}_\Lambda$ (Section 4.6, cf. eq. (4.6)). Vanishing cross-sector expectations imply a block-diagonal (and across the cut, degenerate) inner product, contradicting bundle coherence and continuity demanded by the GNS construction (Definitions 1.34 and 4.287).

(iii) The operator-valued geometric fields $\hat{g}_{\mu\nu}$ and $\hat{t}_{\mu\nu}$ and their expectations $\bar{g}_{\mu\nu}, \bar{t}_{\mu\nu}$ (Definitions 5.1 and 5.26) depend on the same expectation functional. Factorization therefore enforces block structure in $\bar{\Sigma}_{\mu\nu}$, obstructing connected chronogeometry. Together these contradict the IQR postulates of a globally coherent, state-induced geometry; hence $|\mathring{\mathbf{\Psi}}\rangle$ cannot factorize. □

Information-theoretic corollary. If $|\mathring{\mathbf{\Psi}}\rangle$ factorized, the mutual information $I(\mathfrak{B}_x : \mathfrak{B}_{x'})$ would vanish across the partition for $x \in \mathcal{X}_A$, $x' \in \mathcal{X}_B$, contradicting the existence of holosymmetric interference and of induced inter-fibre metrics—both rely on nonzero Holo-State–mediated correlations.

Conclusion. In IQR, entanglement is not optional. It is the *structural* content of the same expectations that (a) *induce* fibre inner products and (b) *determine* expectation-level geometry. Exact factorization drives the theory into a degenerate, classically fragmented limit; the realized universe is therefore supported by a non-factorizable $|\mathring{\mathbf{\Psi}}\rangle$ that sustains connected chronogeometry and the full triad of relational distances and times.

II. Non-Factorizability of $|\mathring{\mathbf{\Psi}}\rangle$: a theorematic constraint of IQR

In a background–independent, relational quantum geometry, the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ cannot be genuinely factorizable across a nontrivial partition of the $\hat{\Omega}$–Continuum. This is not heuristic but a structural consequence of the IQR postulates.

Theorem 4.314 (Non-factorizability of the Holo-State)**.** *Let* $\mathcal{X}_q = \mathcal{X}_A \sqcup \mathcal{X}_B$ *be a nontrivial partition with frame–relative commuting subalgebras* $\mathcal{A}_A, \mathcal{A}_B$*. If* $|\mathring{\mathbf{\Psi}}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle$ *(and hence* $\omega^{\mathring{\mathbf{\Psi}}} = \omega^A \otimes \omega^B$*), then the following fail simultaneously:*

(i) Nontrivial gauge–covariant bilocal channels. *For* $x \in \mathcal{X}_A$*,* $x' \in \mathcal{X}_B$*, expectations of the Fourfold inter–modal correlator* $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ *(Definition 4.9) factorise and generically vanish under parallel transport* $\mathcal{U}(x \leftarrow x'; \gamma)$*, eliminating cross–sector bilocal coherence (cf. Lemma 4.270).*

(ii) Coherent, nondegenerate fibre inner products. *The modal inner product at x is the coincident–limit of Holo-State expectations of $\hat{G}_\Lambda$ (Section 4.6). Vanishing cross–sector expectations force a block–diagonal pairing, destroying bundle coherence across $\mathcal{X}_A \sqcup \mathcal{X}_B$.*

(iii) Connected expectation–level chronogeometry and axis–specific times. *The chronogeometric tensor $\bar{\Sigma}_{\mu\nu}(x)$ (Definition 5.26) inherits the same expectation functional; factorization imposes block structure and obstructs connected chronogeometry, with axis–specific temporal parameters $t_{\mathrm{corr}}, t_{\mathrm{vac}}, t_{\mathrm{spec}}$ undefined or trivial for cross–sector paths (cf. Section 4.12, and the classical specialisation in Section 5.3.8).*

(iv) Holosymmetric interference and induced registers. *Global visibilities (holosymmetric interferometry; Sections 3.1 and 3.1.4) and the emergence of effective registers (Corollary 4.302) require nonzero cross–sector correlator blocks; these are absent under factorization.*

Consequently, exact factorization contradicts the IQR construction; the Holo-State is necessarily non–factorizable.

Proof sketch. (i) Using $\omega^{\mathring{\Psi}} = \omega^A \otimes \omega^B$ and the bilocal channel definition, expectations split as products of one–sector functionals applied to transported operators; for generic mode content and gauge, the cross–sector contribution vanishes (no bilocal coherence), cf. Definition 4.9 and Lemma 4.270. (ii) The inner product is obtained as a coincident–limit of those expectations (Section 4.6); vanishing cross–blocks produce a block–diagonal (across the cut, degenerate) pairing, incompatible with a coherent Hilbert bundle (cf. Definitions 1.34, 4.239 and 4.287). (iii) The same expectation functional defines $\bar{\Sigma}_{\mu\nu}$ (Definition 5.26); factorization forces block structure in $\bar{\Sigma}$, obstructing connected chronogeometry and trivialising axis–specific temporal parameters across the cut (cf. Sections 4.12 and 5.3.8). (iv) Holosymmetric interference functionals and register formation require nonzero cross–sector blocks; these disappear under factorization (Sections 3.1 and 3.1.4 and Corollary 4.302). □

Approximate (FAPP) factorization is allowed. If $\rho \approx \rho_A \otimes \rho_B$ with $\|\rho - \rho_A \otimes \rho_B\|_1 \le \varepsilon$, then for $A \in \mathcal{A}_A$, $B \in \mathcal{A}_B$,

$$\left| \mathrm{Tr}[(\rho - \rho_A \otimes \rho_B)\, A \otimes B] \right| \le \varepsilon\, \|A\|\, \|B\|,$$

so bilocal expectations factorise up to $O(\varepsilon)$. This explains emergent autonomy of subsystems without violating global non–factorizability.

Explanation (FAPP factorization). "FAPP" ("for all practical purposes") means *approximate* factorization at the level of observable consequences, not an exact product state. Let ρ be the actual (possibly correlated) state and $\rho_A \otimes \rho_B$ a product approximation on commuting subalgebras $\mathcal{A}_A, \mathcal{A}_B$ associated to a bipartition (e.g. a frame–relative split of PQS loci; cf. Lemma 4.270). If the *trace distance* is small, $\|\rho - \rho_A \otimes \rho_B\|_1 \le \varepsilon$, then Hölder for Schatten norms and $\|A \otimes B\| = \|A\|\, \|B\|$ give the bound above, hence

$$\mathrm{Tr}(\rho\, A \otimes B) = \mathrm{Tr}(\rho_A A)\ \mathrm{Tr}(\rho_B B)\ \pm\ O(\varepsilon\, \|A\|\, \|B\|).$$

Operationally, if experimental resolution is coarser than the $O(\varepsilon)$ corrections, subsystems behave *autonomously*: cross–correlators are indistinguishable from products. This is compatible with the IQR requirement of *global* non–factorizability (Theorem 4.314) and naturally arises under decoherence, where off–diagonal Fourfold blocks are exponentially suppressed (cf. Proposition 4.312(c)), driving ε small on accessible timescales. Importantly, FAPP factorization is a statement about *expectations*; it does **not** assert that correlator geometry or induced fibre metrics vanish (Section 4.6 and Definition 5.26).

Corollary 4.315 (Information–theoretic obstruction to factorization)**.** *Let $\mathcal{X}_q = \mathcal{X}_A \sqcup \mathcal{X}_B$ be a nontrivial partition with commuting subalgebras $\mathcal{A}_A, \mathcal{A}_B$. If the global state factorizes, $\rho = \rho_A \otimes \rho_B$, then the mutual information*

$$I(A\!:\!B)_\rho \;=\; S(\rho_A) + S(\rho_B) - S(\rho)$$

vanishes, i.e. $I(A\!:\!B)_\rho = 0$. Equivalently, $I(A\!:\!B)_\rho = S\big(\rho \,\big\|\, \rho_A \otimes \rho_B\big) \geq 0$ with equality iff $\rho = \rho_A \otimes \rho_B$ (standard property of relative entropy; see, e.g., [287, 241]). Consequently, any globally coherent IQR configuration exhibiting nonzero holosymmetric visibility across the cut (cf. Sections 3.1 and 3.1.4) or a nondegenerate inter–fibre inner product across the cut (nonvanishing bilocal Fourfold expectations; cf. Section 4.6 and Definition 4.9) must satisfy $I(A\!:\!B)_\rho > 0$ and therefore cannot be exactly factorizable.

Proof sketch. If $\rho = \rho_A \otimes \rho_B$, then $S(\rho) = S(\rho_A) + S(\rho_B)$, so $I(A:B)_\rho = 0$. Conversely, $I(A\!:\!B)_\rho = S(\rho \,\|\, \rho_A \otimes \rho_B)$ equals zero iff $\rho = \rho_A \otimes \rho_B$. Nonzero holosymmetric visibility and nonvanishing cross–sector Fourfold expectations constitute observable correlations across the cut; thus $I(A\!:\!B)_\rho > 0$, which rules out exact factorization. This aligns with Theorem 4.314. □

Exact factorization $\Rightarrow$ no bilocal channels
$\Rightarrow$ block–diagonal fibres & fragmented chronogeometry
$\Rightarrow$ ruled out in IQR.

Corollary 4.316 (Fourfold non-separability enforced by the Holo-State)**.** *Let $\mathcal{A}^{(4)}$ denote the Fourfold Dialectic Algebra of Symmetry (cf. Definition 1.16), generated by the modal channels $\{\hat{\mathcal{F}}_0, \hat{\mathcal{F}}_1, \hat{\mathcal{F}}_p, \hat{\mathcal{F}}_s\}$ (Symmetry, Antisymmetry, Parasymmetry, Holosymmetry; cf. Section 1.2.7), and let π_Ψ be its GNS representation in the Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definitions 1.34 and 4.287). If $|\mathring{\mathbf{\Psi}}\rangle$ is non-factorizable (Theorem Theorem 4.314), then in the represented algebra $\mathcal{M} := \pi_\Psi(\mathcal{A}^{(4)})''$:*

(i) No sector-splitting central projectors

There is no nontrivial $Z \in \mathcal{M} \cap \mathcal{M}'$ that separates $\{0,1\}$ from $\{p,s\}$ or any other Fourfold split. Equivalently, no global superselection splits the Fourfold into tensor- or direct-product components aligned with the modal grading. Otherwise $|\mathring{\mathbf{\Psi}}\rangle$ would factorize across that split, contradicting Theorem 4.314.

(ii) Cross-modal correlators are generically nonzero
Bilocal Fourfold channels $\hat{G}^{\alpha\beta}_{\Lambda}(x,x')$ have nonvanishing Holo-State expectations for cross-modal pairs (e.g. $\alpha \in \{0,1\}$, $\beta \in \{p,s\}$), after gauge-covariant transport (Definition 4.9 and Lemma 4.270). Thus parasymmetric/holosymmetric mixing is a structural *feature, not an artifact.*

(iii) Inner-product and geometry couple all Fourfold channels
The coincident-limit construction of the fibre inner product and the expectation-level chronogeometry (Section 4.6 and Definition 5.26) necessarily involve the off-block Fourfold expectations; a globally coherent metric/chronogeometry requires the coupled Fourfold, not any single channel in isolation.

(iv) Reductions are contingent, not fundamental
Any Twofold (qubit) reduction to $\{0,1\}$ is an effective *block-diagonal regime achieved by dynamical protection and suppressed off-block couplings (Proposition 4.300 and Corollaries 4.301 and 4.302); it does not reflect a decomposition of $\mathcal{A}^{(4)}$, only a controlled truncation of its represented dynamics.*

Sketch. If a central projector split the Fourfold (i), expectations of cross-modal bilocals would vanish identically, implying factorization of $|\overset{\circ}{\mathbf{\Psi}}\rangle$ across that split, contradicting Theorem 4.314. Nonvanishing cross-modal expectations (ii) follow from the same theorem together with the definition of the inter-modal correlator and gauge transport (Definition 4.9 and Lemma 4.270). Items (iii)–(iv) use that the fibre inner product and chronogeometry are induced from those expectations (Section 4.6 and Definition 5.26); when off-block terms are *suppressed* (not absent), the compressed dynamics yields the Twofold/registry effective theory (Proposition 4.300 and Corollary 4.302). □

4.8.3 Wordwise Non-Factorizability of the Holo-State

Setup 4.317 (Partition, commuting subalgebras, and words)**.** Let $\mathcal{X}_q = \mathcal{X}_A \sqcup \mathcal{X}_B$ be a nontrivial partition of PQS loci, and let $\mathcal{A}_A, \mathcal{A}_B$ be the frame–relative commuting subalgebras generated by word–evaluated, typed letters at loci in $\mathcal{X}_A$ and $\mathcal{X}_B$, respectively (Definitions 4.255 and 4.257 and Corollary 4.64). Fix a unitary device word $\mathbf{W}$ and control χ (suppressing χ when clear). For $x \in \mathcal{X}_A$, $x' \in \mathcal{X}_B$ and a path $\gamma : x' \to x$ with transporter $\mathcal{U}(x \leftarrow x';\gamma)$ (Definition 4.248 and Section 4.1.4), define the *wordwise bilocal kernel*

$$\boxed{K^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma) \;:=\; \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big| \Big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\Big)^{\dagger} \mathcal{U}(x \leftarrow x';\gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x') \Big| \overset{\circ}{\mathbf{\Psi}} \Big\rangle,} \tag{4.132}$$

cf. Definition 4.9 and eq. (4.66).

Lemma 4.318 (Exact factorization ⇒ rank-one bilocal kernel)**.** *Assume the Holo–State factorizes across the partition, $|\overset{\circ}{\mathbf{\Psi}}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle$ so that $\omega^{\overset{\circ}{\mathbf{\Psi}}} = \omega^A \otimes \omega^B$. Then, for all $x \in \mathcal{X}_A$, $x' \in \mathcal{X}_B$ and γ,*

$$\boxed{K^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma) = \underbrace{\omega^A\Big(\Big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\Big)^{\dagger}\Big)}_{=:a_\alpha(x)^*} \underbrace{\omega^B\Big(\mathcal{U}(x \leftarrow x';\gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x')\Big)}_{=:b_\beta(x',\gamma)},} \tag{4.133}$$

so the modal kernel has rank at most 1 *as a matrix in* (α,β). *Consequently the wordwise entanglement bilinear* $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ *(Definition 4.332 and eq. (4.144)) factors for all test states.*

Proof. Under factorization, expectations split on commuting subalgebras. The operator $\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\dagger}$ lies in $\mathcal{A}_A$ and $\mathcal{U}\hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x')$ in $\mathcal{A}_B$, hence $\omega^{\mathring{\Psi}}(AB)=\omega^A(A)\,\omega^B(B)$, giving (4.133). Rank–one form implies $\mathsf{E}^{[\mathbf{W}]}_{x,x'}(\psi_1,\psi_2)=\varphi_x(\psi_1)^*\varphi_{x'}(\psi_2)$ with $\varphi_x(\psi_1)=\sum_\alpha a_\alpha\, c^{[\mathbf{W}]}_{1\alpha}(x)$ and $\varphi_{x'}(\psi_2)=\sum_\beta b_\beta\, c^{[\mathbf{W}]}_{2\beta}(x')$. □

Lemma 4.319 (Wordwise collapse of cross–sector interference)**.** *In the setting of Lemma 4.318, the connected wordwise interference* $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}(x;\psi)$ *(eq. (4.143)) across the cut vanishes identically after centering by local means,* $\hat{\mathcal{F}}^{\circ}_{\alpha}:=\hat{\mathcal{F}}_{\alpha}-\omega(\hat{\mathcal{F}}_{\alpha})\mathbf{1}$. *Hence any nontrivial wordwise prismatic superposition (Definition 4.331) cannot bridge* $\mathcal{X}_A$ *to* $\mathcal{X}_B$ *under exact factorization.*

Full proof. Step 0 (Setting and centering). Let $\mathcal{X}_q=\mathcal{X}_A\sqcup\mathcal{X}_B$ as in Setup 4.317 and assume exact factorization $|\mathring{\Psi}\rangle=|\psi_A\rangle\otimes|\psi_B\rangle$ with $\omega^{\mathring{\Psi}}=\omega^A\otimes\omega^B$ (Lemma 4.318). For $x\in\mathcal{X}_A$, $x'\in\mathcal{X}_B$ and a path $\gamma: x'\to x$ with transporter $\mathcal{U}(x\leftarrow x';\gamma)$ (Definition 4.248), set the *transported letter*

$$\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\;:=\;\mathcal{U}(x\leftarrow x';\gamma)\,\hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x').$$

Define centered (connected) letters sectorwise

$$\begin{aligned}\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ}&:=\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)-\omega^A\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)\,\mathbf{1},\\ \big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\big)^{\circ}&:=\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)-\omega^B\big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\big)\,\mathbf{1}.\end{aligned}\tag{4.134}$$

Step 1 (Connected bilocal kernel across the cut). Consider the connected two–point expectation

$$\mathcal{C}^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma):=\;\omega^{\mathring{\Psi}}\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ\dagger}\big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\big)^{\circ}\Big).\tag{4.135}$$

Because $\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ\dagger}\in\mathcal{A}_A$ and $\big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\big)^{\circ}\in\mathcal{A}_B$ (commuting subalgebras; Setup 4.317), factorization yields

$$\mathcal{C}^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma)=\omega^A\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ\dagger}\Big)\,\omega^B\Big(\big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x';\gamma)\big)^{\circ}\Big)=0\cdot 0=0,$$

since each centered one–point function vanishes by construction.

Step 2 (From connected kernel to interference functional). The wordwise interference functional $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}$ (eq. (4.143)) is the *local* specialization $x'=x$ with identity transport and weighted by modal coefficients:

$$\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}(x;\psi)=\omega^{\mathring{\Psi}}\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\dagger}\hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x)\Big)\,\big(c^{[\mathbf{W}]}_{\alpha}(x)\big)^{*}\,c^{[\mathbf{W}]}_{\beta}(x).$$

To assess *cross–cut* coherence, replace the local kernel by the bilocal, connected kernel (4.135) and coefficients on the respective loci (cf. the bilinear entanglement form, Definition 4.332 and eq. (4.144)). The result vanishes by Step 1:

$$\big(\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}\big)_{\text{across cut}}\;\propto\;\mathcal{C}^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma)\,\big(c^{[\mathbf{W}]}_{1,\alpha}(x)\big)^{*}\,c^{[\mathbf{W}]}_{2,\beta}(x')\;=\;0.$$

Step 3 (Conclusion for prismatic superposition). By Definition 4.331, a nontrivial wordwise prismatic superposition across a set S requires at least one pair $\alpha \neq \beta$ with nonzero interference functional. Since the connected cross–sector contribution vanishes identically under exact factorization, no coherent superposition can *bridge* $\mathcal{X}_A$ to $\mathcal{X}_B$. Equivalently, any apparent cross–cut "superposition'' reduces to a mixture, consistent with the rank–one (factorized) bilocal kernel of Lemma 4.318 and the factorization of the entanglement bilinear (Definition 4.332).

Gauge/word invariance. All steps are invariant under endpoint gauge and word changes, because centering uses sectorwise expectations and the transformations act by unitary conjugations that preserve ω^A, ω^B (Propositions 4.54 and 4.284 and Corollary 4.64).

This establishes the claim. □

Proposition 4.320 (Block structure of induced pairings and geometry (wordwise))**.** *Let the fibre inner product and expectation–level chronogeometry be induced from wordwise correlators (Section 4.6 and Definition 5.26). Under exact factorization, all cross–sector contributions to the coincident–limit pairings and to the chronogeometric tensor vanish; the Hilbert bundle and the expectation-level geometry decompose as a block direct sum across $\mathcal{X}_A \sqcup \mathcal{X}_B$.*

Proof idea. The inner product at a locus is obtained as a coincident limit of (4.132). Cross–sector limits employ kernels of the form (4.133); their connected part vanishes, yielding block diagonality. The same expectation functional determines $\bar{\Sigma}_{\mu\nu}$ (Definition 5.26), so cross–sector components are zero.

Full proof. Step 0 (Setting). Partition $\mathcal{X}_q = \mathcal{X}_A \sqcup \mathcal{X}_B$ with commuting frame–relative subalgebras $\mathcal{A}_A, \mathcal{A}_B$ (Setup 4.317). Assume exact factorization of the Holo–State, $|\overset{\circ}{\boldsymbol{\Psi}}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle$ so that $\omega^{\overset{\circ}{\boldsymbol{\Psi}}} = \omega^A \otimes \omega^B$. For $x \in \mathcal{X}_A$, $x' \in \mathcal{X}_B$ and any path $\gamma : x' \to x$ with transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ (Definition 4.248), consider the wordwise bilocal kernel

$$K^{[\mathbf{W}]}_{\alpha\beta}(x, x'; \gamma) = \left\langle \overset{\circ}{\boldsymbol{\Psi}} \,\middle|\, \big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\dagger}\, \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x') \,\middle|\, \overset{\circ}{\boldsymbol{\Psi}} \right\rangle \qquad (\textit{eq. } (4.132)).$$

Step 1 (Rank–one structure across the cut). By factorization and commutativity of $\mathcal{A}_A$ with $\mathcal{A}_B$,

$$K^{[\mathbf{W}]}_{\alpha\beta}(x, x'; \gamma) = \underbrace{\omega^A\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\dagger}\Big)}_{=:a_\alpha(x)^*}\, \underbrace{\omega^B\Big(\mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x')\Big)}_{=:b_\beta(x', \gamma)},$$

so the modal matrix is rank ≤ 1 (Lemma 4.318, eq. (4.133)). If we center letters sectorwise,

$$\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ} := \hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x) - \omega^A(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x))\, \mathbf{1}, \quad \big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x'; \gamma)\big)^{\circ} := \mathcal{U}\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x') - \omega^B(\mathcal{U}\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x'))\, \mathbf{1},$$

then the connected cross–sector kernel vanishes identically:

$$\omega^{\overset{\circ}{\boldsymbol{\Psi}}}\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\big)^{\circ\,\dagger}\, \big(\widetilde{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x'; \gamma)\big)^{\circ}\Big) = 0,$$

cf. Lemma 4.319.

Step 2 (Induced inner product: coincident limit and block–diagonality). The fibre inner product at x is defined as a coincident limit of such kernels (exogenous or wordwise, the constructions agree up to endpoint gauge; see Section 4.6): for local coefficient vectors $c, d \in \mathbb{C}^4$,

$$\Big\langle \psi, \phi \Big\rangle_x = \lim_{x' \to x} \sum_{\alpha,\beta} c_\alpha^* \, d_\beta \, K_{\alpha\beta}^{[\mathbf{W}]}(x, x'; \gamma), \qquad |\psi\rangle = \sum_\alpha c_\alpha |\alpha\rangle, \quad |\phi\rangle = \sum_\beta d_\beta |\beta\rangle. \tag{4.136}$$

Take the decomposition of the kernel into its centered (connected) and mean parts. The connected cross–sector part is zero by Step 1; the mean part factorizes into sectorwise numbers that do not depend on the opposite state coefficients. Therefore the cross–sector contribution to (4.136) vanishes in the coincident limit, and the pairing reduces to a sum of *intra–sector* terms. Equivalently, in any local frame adapted to the partition the Gram matrix of $\langle \cdot, \cdot \rangle_x$ is block diagonal with respect to $\mathcal{X}_A \sqcup \mathcal{X}_B$.

Step 3 (Expectation–level chronogeometry). Let $\bar{\Sigma}_{\mu\nu}(x) = \omega^{\mathring{\Psi}}\big(\hat{\Sigma}_{\mu\nu}(x)\big)$ be the chronogeometric tensor defined from the same expectation functional (Definition 5.26). Its construction (via composite two–point objects and appropriate contractions in the coincident limit; cf. Definition 5.26 and Section 4.6) employs the same bilocal kernels. Repeating the centering/-factorization argument shows that any cross–sector component of $\bar{\Sigma}_{\mu\nu}$ vanishes: connected cross–sector contributions are zero, while the mean parts factor into independent sectorwise numbers that do not produce cross terms upon coincidence. Hence $\bar{\Sigma}_{\mu\nu}$ is block diagonal across the partition.

Step 4 (Decomposition of bundle and geometry). Block–diagonality of the fibre pairing at each x implies that the modal bundle splits as an orthogonal Whitney sum of subbundles supported on $\mathcal{X}_A$ and $\mathcal{X}_B$:

$$\mathscr{H}_{\mathrm{mod}} \;\cong\; \mathscr{H}_{\mathrm{mod}}|_{\mathcal{X}_A} \;\oplus\; \mathscr{H}_{\mathrm{mod}}|_{\mathcal{X}_B},$$

with connection data reducing accordingly (no cross–sector parallel coupling). The expectation–level chronogeometry likewise decomposes: the metric/temporal tensors are block diagonal and define disconnected components on $\mathcal{X}_A$ and $\mathcal{X}_B$. Gauge and word changes act by endpoint/fibrewise unitary conjugations and do not affect the vanishing of connected cross–sector expectations (Propositions 4.54 and 4.284 and Corollary 4.64), so the conclusion is invariant.

Therefore, under exact factorization, cross–sector contributions to both the induced inner product and the chronogeometric tensor vanish, and the theory decomposes as a block direct sum across $\mathcal{X}_A \sqcup \mathcal{X}_B$. □

Theorem 4.321 (Wordwise necessity of non-factorizability)**.** *Assume the IQR postulates of: (i) nontrivial, gauge–covariant bilocal Fourfold channels (Definition 4.9), (ii) a coherent, nondegenerate fibre inner product at all loci (Section 4.6), and (iii) connected expectation-level chronogeometry (Definition 5.26). Then the Holo–State $|\mathring{\Psi}\rangle$ cannot factorize across any nontrivial partition of $\mathcal{X}_q$.*

Proof idea. Suppose $|\mathring{\Psi}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle$. By Lemma 4.318, bilocal kernels across the cut are rank-one and therefore yield no nontrivial wordwise entanglement; by Lemma 4.319 no

connected cross-sector interference survives. This contradicts (i). By Proposition 4.320, the induced inner product and chronogeometry block–decompose, violating (ii) and (iii). Hence the assumption is false.

Full proof. We proceed by contradiction. Let $\mathcal{X}_q = \mathcal{X}_A \sqcup \mathcal{X}_B$ be a nontrivial partition with commuting, frame–relative subalgebras $\mathcal{A}_A, \mathcal{A}_B$ as in Setup 4.317, and suppose

$$|\overset{\circ}{\mathbf{\Psi}}\rangle = |\psi_A\rangle \otimes |\psi_B\rangle\,, \qquad \omega^{\overset{\circ}{\mathbf{\Psi}}} = \omega^A \otimes \omega^B. \tag{4.137}$$

Step 1 (Bilocal kernel becomes rank–one ⇒ no nontrivial channels). For $x \in \mathcal{X}_A$, $x' \in \mathcal{X}_B$ and any path $\gamma : x' \to x$ with transporter $\mathcal{U}(x \leftarrow x'; \gamma)$ (Definition 4.248), the wordwise bilocal kernel

$$K^{[\mathbf{W}]}_{\alpha\beta}(x, x'; \gamma) = \left\langle \overset{\circ}{\mathbf{\Psi}} \,\middle|\, \big(\hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha(x)\big)^\dagger \mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_\beta(x') \,\middle|\, \overset{\circ}{\mathbf{\Psi}} \right\rangle \qquad (\textit{eq. (4.132)})$$

factorizes by (4.137) into a product of one–side functionals:

$$K^{[\mathbf{W}]}_{\alpha\beta}(x, x'; \gamma) = \omega^A\Big(\big(\hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha(x)\big)^\dagger\Big)\, \omega^B\Big(\mathcal{U}(x \leftarrow x'; \gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_\beta(x')\Big), \tag{4.138}$$

i.e. a rank–one matrix in the modal indices (α, β) (Lemma 4.318). After centering sector-wise, $(\hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha)^\circ := \hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha - \omega(\hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha)\mathbf{1}$, the connected cross–sector kernel vanishes identically (Lemma 4.319). Hence there is no nontrivial, gauge–covariant bilocal Fourfold channel across the cut in the sense of Definition 4.9. This contradicts Postulate (i).

Step 2 (Coincident–limit pairing block–diagonalizes ⇒ loss of cross–sector coherence). The fibre inner product at x is obtained from coincident limits of such kernels (exogenous/wordwise constructions agree up to endpoint gauge; Section 4.6):

$$\langle \psi, \phi \rangle_x = \lim_{x' \to x} \sum_{\alpha,\beta} c^*_\alpha d_\beta\, K^{[\mathbf{W}]}_{\alpha\beta}(x, x'; \gamma) \quad \text{for} \quad |\psi\rangle = \sum_\alpha c_\alpha |\alpha\rangle, \quad |\phi\rangle = \sum_\beta d_\beta |\beta\rangle. \tag{4.139}$$

With (4.138) and the vanishing of the connected cross–sector part (Lemma 4.319), the cross–sector contribution to (4.139) disappears in the limit, leaving only intra–sector terms. Thus the Gram matrix of $\langle \cdot, \cdot \rangle_x$ is block–diagonal in a frame adapted to $\mathcal{X}_A \sqcup \mathcal{X}_B$ and the modal bundle splits orthogonally. Equivalently, the bundle fails to provide coherent cross–sector comparison, i.e. the induced pairing does not *glue* across the cut. This is precisely the block–decomposition stated in Proposition 4.320 and violates the "coherent" part of Postulate (ii) (nondegeneracy can hold on each block, but coherence across the partition is lost).

Step 3 (Expectation–level chronogeometry fragments). The chronogeometric tensor $\bar{\Sigma}_{\mu\nu}(x) = \omega^{\overset{\circ}{\mathbf{\Psi}}}(\hat{\Sigma}_{\mu\nu}(x))$ is built from the same bilocal correlators in a coincident–limit construction (Definition 5.26). By the same centering/factorization argument as in Step 2, all cross–sector components vanish and $\bar{\Sigma}_{\mu\nu}$ becomes block–diagonal across $\mathcal{X}_A \sqcup \mathcal{X}_B$ (Proposition 4.320). Therefore the expectation–level chronogeometry decomposes into disconnected pieces, contradicting Postulate (iii).

Step 4 (Holonomy witness is quenched under factorization). Independently of Steps 2–3, small–loop wordwise holonomy in the s–channel provides a local, gauge–invariant witness of connected chronogeometry:

$$\hat{H}^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = \Big(\hat{\mathcal{F}}^{[\mathbf{W}]}_s(x)\Big)^\dagger \Big(\mathbf{1}_4 - \varepsilon^2\,\Phi_x(\mathcal{F}) + O(\varepsilon^3)\Big)\,\hat{\mathcal{F}}^{[\mathbf{W}]}_s(x), \tag{4.140}$$
$$h^{(s)[\mathbf{W}]}_{\ell_\varepsilon}(x) = h^{(s)[\mathbf{W}]}_{\text{flat}}(x) - \varepsilon^2\,\omega\Big((\hat{\mathcal{F}}^{[\cdot]}_s)^\dagger \Phi_x(\mathcal{F})\hat{\mathcal{F}}^{[\cdot]}_s\Big) + O(\varepsilon^3).$$

(Corollary 4.298 and eqs. (4.98) and (4.99)). Under (4.137), the cross–sector contribution in the expectation reduces to a product of sector means (rank–one), so the genuinely nonlocal term proportional to $\Phi_x(\mathcal{F})$ is quenched across the cut. Thus even infinitesimal holonomy readouts cannot register a cross–sector twist, again contradicting Postulate (iii) whenever curvature or nontrivial topology is present.

Step 5 (Gauge/word invariance of the contradiction). All preceding steps rely on identities of expectations under sectorwise centering and use only the commuting structure of $\mathcal{A}_A, \mathcal{A}_B$; endpoint gauge and word changes act by unitary conjugation and preserve the factorization arguments (Propositions 4.54 and 4.284 and Corollary 4.64). Hence the contradictions are not artefacts of a particular gauge/word choice.

Since (4.137) simultaneously violates Postulates (i)–(iii), our assumption is false. Therefore $|\mathring{\mathbf{\Psi}}\rangle$ cannot factorize across any nontrivial partition of $\mathcal{X}_q$. □

Remark 4.322 (Holonomy and small-loop witnesses)**.** If $\mathcal{F} \neq 0$ near a cut, the wordwise small–loop sensitivity (Corollary 4.298 and eqs. (4.98) and (4.99)) produces an s–channel signal linear in the oriented area: a strictly local, gauge-invariant witness of connected chronogeometry. Exact factorization would force such cross–sector loop signals to reduce to rank-one (or centered zero) contributions, contradicting the existence of nontrivial holonomy readouts.

Proposition 4.323 (FAPP wordwise factorization)**.** *Let ρ be the actual state and $\rho_A \otimes \rho_B$ a product approximation on $\mathcal{A}_A \otimes \mathcal{A}_B$ with $\|\rho - \rho_A \otimes \rho_B\|_1 \le \varepsilon$. Then for any wordwise bilocal $O_A \in \mathcal{A}_A$, $O_B \in \mathcal{A}_B$,*

$$\boxed{\Big|\,\mathrm{Tr}\Big[\rho\, O_A \otimes O_B\Big] - \mathrm{Tr}(\rho_A O_A)\;\mathrm{Tr}(\rho_B O_B)\Big| \;\le\; \varepsilon\,\|O_A\|\,\|O_B\|,} \tag{4.141}$$

so wordwise kernels and holonomy signals factorize up to $O(\varepsilon)$. Thus emergent autonomy of subsystems is compatible with global non-factorizability (Theorem 4.321).

Proof idea. The key step is the noncommutative Hölder (duality) inequality for Schatten norms: for any trace–class operator $T \in \mathsf{S}_1$ and bounded operator $X \in \mathsf{S}_\infty$,

$$\Big|\,\mathrm{Tr}(TX)\Big| \;\le\; \|T\|_1\,\|X\|_\infty,$$

with the usual generalisation $\|AB\|_r \le \|A\|_p \|B\|_q$ for $1/p+1/q = 1/r$ (see, e.g., [356, 253, 381]). Setting $T = \rho - \rho_A \otimes \rho_B$ and $X = O_A \otimes O_B$ gives

$$\Big|\,\mathrm{Tr}[(\rho - \rho_A \otimes \rho_B)(O_A \otimes O_B)]\Big| \;\le\; \|\rho - \rho_A \otimes \rho_B\|_1\,\|O_A \otimes O_B\|_\infty.$$

Using the projective property of the operator norm on simple tensors, $\|O_A \otimes O_B\| = \|O_A\|\,\|O_B\|$ (e.g. [356]), yields the stated bound (4.141). The same estimate applies termwise to any finite linear combination of simple tensors, hence to the wordwise bilocal kernel (4.132) and to the loop operator (4.122) after word evaluation, by linearity and the triangle inequality. Conceptually, Hölder–Schatten duality is crucial because it converts a *global* closeness in trace distance into a *uniform* $O(\varepsilon)$ control of all cross–sector expectations, establishing "FAPP" factorization at the level of observable consequences while remaining gauge/word invariant.

Full proof. Step 0 (Notation and norms). Let $\Delta := \rho - \rho_A \otimes \rho_B$. By hypothesis $\|\Delta\|_1 \le \varepsilon$. We use Schatten duality (Hölder for Schatten norms): for any trace–class T and bounded X, $|\operatorname{Tr}(TX)| \le \|T\|_1\,\|X\|$. Moreover $\|O_A \otimes O_B\| = \|O_A\|\,\|O_B\|$ for operator norm.

Step 1 (Basic inequality). Compute

$$\operatorname{Tr}\Big[\rho\, O_A \otimes O_B\Big] - \operatorname{Tr}(\rho_A O_A)\,\operatorname{Tr}(\rho_B O_B) = \operatorname{Tr}\Big[\,(\rho - \rho_A \otimes \rho_B)\,(O_A \otimes O_B)\,\Big] = \operatorname{Tr}\Big[\Delta\,(O_A \otimes O_B)\Big].$$

Apply Hölder:

$$\Big|\operatorname{Tr}\Big[\Delta\,(O_A \otimes O_B)\Big]\Big| \;\le\; \|\Delta\|_1\,\|O_A \otimes O_B\| \;=\; \varepsilon\,\|O_A\|\,\|O_B\|,$$

which is precisely (4.141).

Step 2 (Application to wordwise bilocal kernels). For the wordwise bilocal kernel (eq. (4.132)),

$$K^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma) = \Big\langle \overset{\circ}{\mathbf{\Psi}} \Big|\, \Big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x)\Big)^{\dagger}\, \mathcal{U}(x \leftarrow x';\gamma)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x') \,\Big|\, \overset{\circ}{\mathbf{\Psi}} \Big\rangle,$$

identify $O_A = (\hat{\mathcal{F}}^{[\mathbf{W}]}_{\alpha}(x))^{\dagger} \in \mathcal{A}_A$ and $O_B = \mathcal{U}(x \leftarrow x';\gamma)\,\hat{\mathcal{F}}^{[\mathbf{W}]}_{\beta}(x') \in \mathcal{A}_B$ ($\mathcal{A}_A, \mathcal{A}_B$ commute by construction; cf. Setup 4.317 and Definition 4.248). Then (4.141) gives

$$\Big|\, K^{[\mathbf{W}]}_{\alpha\beta}(x,x';\gamma) - \operatorname{Tr}(\rho_A O_A)\,\operatorname{Tr}(\rho_B O_B) \,\Big| \;\le\; \varepsilon\,\|O_A\|\,\|O_B\|. \tag{4.142}$$

Thus the kernel *factorizes up to* $O(\varepsilon)$ into sectorwise expectations, uniformly controlled by the operator norms. In particular, all bilinear functionals built from the kernel (e.g. the wordwise entanglement bilinear in Definition 4.332 and eq. (4.144)) inherit the same $O(\varepsilon)$ control.

Step 3 (Application to holonomy signals). For the wordwise holosymmetric loop operator at x,

$$\hat{H}^{(s)[\mathbf{W}]}_{\ell}(x) = \Big(\hat{\mathcal{F}}^{[\mathbf{W}]}_{s}(x)\Big)^{\dagger}\, \mathcal{U}_{\ell}(x)\, \hat{\mathcal{F}}^{[\mathbf{W}]}_{s}(x) \qquad (\textit{eq. (4.122)}),$$

two situations occur:

(a) If $\hat{H}^{(s)[\mathbf{W}]}_{\ell}(x)$ is supported entirely in $\mathcal{A}_A$, take $O_A = \hat{H}^{(s)[\mathbf{W}]}_{\ell}(x)$, $O_B = \mathbf{1}$. Then

$$\Big|\operatorname{Tr}\Big(\rho\,\hat{H}^{(s)[\mathbf{W}]}_{\ell}(x)\Big) - \operatorname{Tr}\Big(\rho_A\,\hat{H}^{(s)[\mathbf{W}]}_{\ell}(x)\Big)\Big| \le \varepsilon\,\|\hat{H}^{(s)[\mathbf{W}]}_{\ell}(x)\|.$$

(b) If the loop word splits across the cut (e.g. a device word whose typed letters act in both sectors along ℓ), write it as a finite sum of simple tensors $\sum_j A_j \otimes B_j$ (by

linearity of the evaluation functor; cf. Definition 4.255 and Proposition 4.284). Apply (4.141) termwise and sum:

$$\left|\operatorname{Tr}\left(\rho\,\hat{H}_\ell^{(s)[\mathbf{W}]}\right)-\operatorname{Tr}\left(\rho_A\otimes\rho_B\,\hat{H}_\ell^{(s)[\mathbf{W}]}\right)\right| \;\le\; \varepsilon\sum_j \|A_j\|\,\|B_j\| \;\le\; \varepsilon\,\|\hat{H}_\ell^{(s)[\mathbf{W}]}\|_\gamma,$$

where $\|\cdot\|_\gamma$ is any projective cross–norm dominating $\sum_j \|A_j\|\,\|B_j\|$; in particular the operator norm bound $\varepsilon\,\|\hat{H}_\ell^{(s)[\mathbf{W}]}\|$ suffices.

Hence holonomy expectations "factorize" to product-state predictions up to $O(\varepsilon)$, consistent with the small–loop expansion in Corollary 4.298 and eq. (4.99).

Step 4 (Connected/centered quantities and robustness). If one prefers connected (centered) observables, define $O_A^\circ := O_A - \operatorname{Tr}(\rho_A O_A)\mathbf{1}$, $O_B^\circ := O_B - \operatorname{Tr}(\rho_B O_B)\mathbf{1}$. Then

$$\left|\operatorname{Tr}\left[\rho\,O_A^\circ\otimes O_B^\circ\right]\right| = \left|\operatorname{Tr}\left[\Delta\,O_A^\circ\otimes O_B^\circ\right]\right| \le \varepsilon\,\|O_A\|\,\|O_B\|,$$

so connected cross–sector correlations are $O(\varepsilon)$. If $\rho_A = \operatorname{Tr}_B\rho$ and $\rho_B = \operatorname{Tr}_A\rho$ are chosen (optional), contractivity of the partial trace in trace norm implies $\|\operatorname{Tr}_B\rho - \rho_A\|_1 \le \varepsilon$, so the same bounds hold with the true marginals, strengthening the interpretation.

Step 5 (Gauge/word invariance). Endpoint gauge and word changes act by fibrewise unitary conjugations that preserve operator norms and expectations in (4.141) (Propositions 4.54 and 4.284 and Corollary 4.64); the bounds are therefore invariant.

Combining Steps 1–3 proves (4.141) and its consequences for wordwise kernels and holonomy signals. This establishes that *approximate* (FAPP) factorization of expectations coexists with global non–factorizability (Theorem 4.321). □

Corollary 4.324 (No Fourfold sector–splitting central projectors (wordwise GNS))**.** *Let $\mathcal{A}^{(4)}$ be the Fourfold word algebra and π_Ψ its GNS representation in $|\mathring{\mathbf{\Psi}}\rangle$ (Definitions 1.34 and 4.287). If $|\mathring{\mathbf{\Psi}}\rangle$ is non-factorizable (Theorem Theorem 4.321), then the von Neumann algebra $\mathcal{M} = \pi_\Psi(\mathcal{A}^{(4)})''$ admits no nontrivial $Z \in \mathcal{M}\cap\mathcal{M}'$ that splits $\{0,1\}$ from $\{p,s\}$. Otherwise the state would factorize across that split, contradicting the theorem.*

Summary. In the endogenous alphabets-and-words formalism, exact factorization forces bilocal wordwise kernels to rank-one (Lemma 4.318), collapses connected interference and prismatic superposition across the cut (Lemma 4.319), and block–diagonalizes the induced inner product and chronogeometry (Proposition 4.320). This conflicts with the IQR postulates of nontrivial bilocal channels, coherent fibres, and connected chronogeometry, hence the Holo-State must be non-factorizable (Theorem 4.321). Approximate (FAPP) factorization remains valid with quantitative bounds (Proposition 4.323).

Non-factorizability as a structural necessity. In the IQR construction the universal Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ simultaneously (i) conditions the Fourfold operator content at each PQS and (ii) *induces* both the fibre inner products and the expectation–level geometry via its correlators (Definitions 1.25, 4.9 and 5.26 and Section 4.6). The endogenous (alphabets–and–words) argument shows that an *exact* product across a nontrivial partition forces contradictions with

those very inductions: one cannot retain nontrivial bilocal channels, a coherent nondegenerate fibre metric at every locus, and a connected chronogeometry if $|\mathring{\mathbf{\Psi}}\rangle$ factors. Formally, this is captured by the wordwise non–factorizability theorem (Theorem 4.321).

Operational meaning of the "rank–one kernel." If $|\mathring{\mathbf{\Psi}}\rangle$ factored, the word–evaluated bilocal kernel linking modes at x and x' would split as a product of *one–side* functionals, i.e. become rank–one in its modal indices (Lemma 4.318). Operationally this means every cross–region correlation is just "what A does" times "what B does''—no shared phase information, no genuinely joint structure. In the endogenous language, the entanglement bilinear $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ (Definition 4.332 and eq. (4.144)) *factors* for all tests, so ontological entanglement across the cut is impossible.

Geometric fragmentation as a consequence. The inner products on fibres are obtained as coincident limits of those same kernels, and the expectation–level chronogeometry uses the same expectation functional (Section 4.6 and Definition 5.26). Once the cross–sector pieces of the kernel are rank–one (and their connected parts vanish), the induced pairing becomes block–diagonal and the geometry decomposes along the partition. The result is a bundle and metric that *fragment* into operator–disconnected components, contradicting the postulated connected chronogeometry (Proposition 4.320 and Definition 4.248).

Holonomy as a local witness (and why it would go flat). Small–loop holonomy in the holosymmetric s–channel is designed to register curvature or topology at the expectation level: the wordwise loop operator and its signal shift linearly with the loop's oriented area to lowest order (eqs. (4.99) and (4.122) and Corollary 4.298). Exact factorization collapses the cross–sector contribution to a rank–one (product) form, so the *genuinely nonlocal* twist written into the signal disappears. Put plainly: the very dial meant to detect global fibre gluing would read "no twist'' across the cut.

No coherent superposition across the cut. Superposition in this framework is diagnosed by a nonzero wordwise interference functional between at least two modal directions (Definition 4.331 and eq. (4.143)). Under exact factorization, the connected cross–sector interference vanishes identically after centring by local means, so coherent superpositions cannot bridge the partition; only mixtures remain (Lemma 4.319). This aligns with the collapse of the bilocal kernel and the loss of parasymmetric, phase–sensitive effects across the cut.

Entanglement is structural; qubits are effective. Because the same expectations that power interference also *define* the fibre metric and chronogeometry, entanglement is not an add–on resource but part of the load–bearing structure of the theory (Section 4.8.5 and Definition 4.332). Twofold (qubit–like) behaviour still emerges when a wordwise Twofold sector is dynamically protected and off–block mixing is negligible, yielding an isometric embedding and standard qubit kinematics; registers arise when cross–correlators between selected fibres are perturbatively suppressed (Propositions 4.300 and 4.335 and Corollary 4.302). But that is an *effective* reduction inside a genuinely Fourfold world.

Why subsystems often look independent (FAPP factorization). Approximate products in trace distance make all bilocal expectations *behave* like products up to a quantitative tolerance (Proposition 4.323). This explains the everyday autonomy of subsystems—decoherence and engineering can suppress off–block terms so that, within resolution, cross–cut signals are indistinguishable from products—without asserting that the global Holo–State truly factors. In short, only *approximate* separability is compatible with the same correlations that both knit geometry and underwrite nonclassical phenomena.

4.8.4 Fourfold Prismatic Superposition and Entanglement

Definition 4.325 (Prismatic Superposition at a Locus)**.** Fix a locus $\mathfrak{B}_x$. Let the modal fibre be $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = \mathrm{span}\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$, with inner product induced by the coincident limit of the Fourfold correlator as in Section 4.6. Write the correlator channels as $\hat{\mathcal{F}}_\alpha(x)$ so that $\hat{G}_\Lambda^{\alpha\beta}(x,x') = \left\langle \hat{\mathcal{F}}_\alpha(x)^\dagger \mathcal{U}_{x\to x'} \hat{\mathcal{F}}_\beta(x') \right\rangle$. Given a nonzero vector $|\psi\rangle_x = \sum_{\alpha\in\{0,1,p,s\}} c_\alpha |\alpha\rangle_x$, we say that $|\psi\rangle_x$ is a *(nontrivial) prismatic superposition across* $S \subseteq \{0,1,p,s\}$ if $|S| \geq 2$, its projection onto $\mathrm{span}\{|\alpha\rangle_x : \alpha \in S\}$ has at least two nonzero modal components, and there exists $\alpha \neq \beta$ in S with nonvanishing interference functional

$$\mathsf{I}_{\alpha\beta}(x\,;\psi) \;:=\; \left\langle \mathring{\mathbf{\Psi}} \,\middle|\, \hat{\mathcal{F}}_\alpha(x)^\dagger \hat{\mathcal{F}}_\beta(x) \,\middle|\, \mathring{\mathbf{\Psi}} \right\rangle (c_\alpha)^* c_\beta \;\neq\; 0.$$

Thus "superposition" is the *S-facet* (coherent coexistence) realised on the prism's modes.

Definition 4.326 (Ontological Entanglement Between Loci)**.** For loci $\mathfrak{B}_x, \mathfrak{B}_{x'}$ with test states $|\psi_1\rangle_x = \sum_\alpha c_{1\alpha}|\alpha\rangle_x$ and $|\psi_2\rangle_{x'} = \sum_\beta c_{2\beta}|\beta\rangle_{x'}$, define the bilinear form

$$\mathsf{E}_{x,x'}(\psi_1,\psi_2) \;:=\; \left\langle \mathring{\mathbf{\Psi}} \middle| \hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})[\psi_1^*,\psi_2] \middle| \mathring{\mathbf{\Psi}} \right\rangle,$$

with parallel transport as in eq. (4.131). We say the Holo-State exhibits *entanglement* between x and x' iff $\mathsf{E}_{x,x'}$ does *not* factor as $\varphi_x(\psi_1)^*\varphi_{x'}(\psi_2)$ for any linear functionals $\varphi_x, \varphi_{x'}$ on the respective modal fibres. Equivalently, the kernel $(\langle \hat{\mathcal{F}}_\alpha(x)^\dagger \mathcal{U}\, \hat{\mathcal{F}}_\beta(x')\rangle)_{\alpha,\beta}$ has rank > 1 with respect to modal indices when evaluated in $|\mathring{\mathbf{\Psi}}\rangle$.

Proposition 4.327 (Compatibility with the Fourfold Symmetry Algebra (Parasymmetric tests))**.** *On the Twofold slice* $\mathrm{span}\{|0\rangle_x, |1\rangle_x\}$*, let* $P_{\mathrm{para}}, P_{\mathrm{antipara}}$ *denote the parasymmetric and anti-parasymmetric effects (with* $P_{\mathrm{para}} + P_{\mathrm{antipara}} = P_{(0,1)}$*). Then for any* $|\psi\rangle_x = c_0|0\rangle_x + c_1|1\rangle_x$*,*

$$\left\langle P_{\mathrm{para}} \right\rangle_\psi = \tfrac{1}{2}\Big(\langle \hat{\mathcal{F}}_0^\dagger \hat{\mathcal{F}}_0 \rangle\, |c_0|^2 + \langle \hat{\mathcal{F}}_1^\dagger \hat{\mathcal{F}}_1 \rangle\, |c_1|^2 + 2\,\mathrm{Re}\, \mathsf{I}_{01}(x;\psi) \Big)\,.$$

Hence $|\psi\rangle_x$ *is a prismatic superposition across* $\{0,1\}$ *iff the parasymmetric/anti-parasymmetric pair yields a nontrivial, phase-sensitive split on* $|\psi\rangle_x$*; the superposition functional* I_{01} *is exactly the interference term in the Born valuation of* P_{para}*.*

Proposition 4.328 (Reduction to Standard Hilbert-Space Notions in the Twofold Regime)**.** *If the duality-collapse regime holds at (each of)* x *(and* x'*) in the sense of Definition 4.87, then there exist isometries* $U_x : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}\,(0,1)}^{(\mathfrak{B}_x)}$ *(and similarly at* x'*) such that:*

(i) $|\psi\rangle_x$ *is a prismatic superposition across* $\{0,1\}$ *iff* $U_x^\dagger|\psi\rangle_x$ *is a nontrivial linear combination in* $\mathbb{C}^2$*;*

(ii) entanglement between (x,x') *in Definition 4.326 holds iff the induced two–qubit state on* $\mathbb{C}^2\otimes\mathbb{C}^2$ *is entangled in the standard sense.*

Sketch. *The inner product on the Twofold fibre is induced by the restricted correlator; Definition 4.87 and Proposition 4.90 give the isometric identifications. Factorisation/nonfactorisation of* $\mathsf{E}_{x,x'}$ *reduces to product/nonproduct states after compression by* $U_x^\dagger\otimes U_{x'}^\dagger$*.*

Remark 4.329 (Basis/Transport Invariance)**.** The predicates in Definitions 4.325 and 4.326 are invariant under admissible reindexings and under the duality involution (cf. Proposition 1.8), and they are unaffected by parallel-transport gauge choices: changes $\hat{\mathcal{F}}_\alpha\mapsto e^{\mathrm{i}\phi_\alpha}\hat{\mathcal{F}}_\alpha$ or unitary changes of $\mathcal{U}$ that preserve the correlator class leave $\mathsf{I}_{\alpha\beta}$ and the factorisation test for $\mathsf{E}_{x,x'}$ unchanged.

Lemma 4.330 (Holosymmetric Dominance)**.** *Assume the holosymmetric effect* $E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ *of eq. (3.36), with* $\mathbf{U}_{\mathrm{holo}}$ *constructed from the Fourfold channel algebra and lifted path unitaries (cf. Definition 2.102 and Section 2.3.2). Then:*

(i) (Local) *If, for some fibre preparation* $|\psi\rangle_x$*, the control readout is* phase–sensitive *(changes under a control-basis rotation with registers fixed), then there exist modal indices* $\alpha\neq\beta$ *with* $\mathsf{I}_{\alpha\beta}(x;\psi)\neq 0$ *as in Definition 4.325.*

(ii) (Bilocal) *If a holosymmetric bipartite test between* (x,x') *signals nonseparability, then the bilinear form* $\mathsf{E}_{x,x'}$ *of Definition 4.326 does not factor.*

Sketch. Write $v_H(\rho_{\mathrm{RR}})=\mathrm{Tr}\big(E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}\rho_{\mathrm{RR}}\big)$ with $E_{\mathrm{Holo}}^{(\mathbf{a}\to\mathbf{b})}$ from eq. (3.36). In the canonical interferometer the control signal depends on the overlap operator $K:=U_G^\dagger U_N$ of the two lifted global evolutions acting on the same register input. A phase–sensitive change under a control Hadamard implies K has nonzero off–diagonal matrix elements in the Fourfold modal basis; since K is built from the channel operators $\hat{\mathcal{F}}_\alpha$, some $\langle\hat{\mathcal{F}}_\alpha^\dagger\hat{\mathcal{F}}_\beta\rangle\neq 0$ with $\alpha\neq\beta$, yielding $\mathsf{I}_{\alpha\beta}(x;\psi)\neq 0$ (i). For (ii), nonseparability of the holosymmetric readout forces nonzero matrix elements of the bilocal kernel $\langle\,\hat{\mathcal{F}}_\alpha(x)^\dagger\mathcal{U}(x\leftarrow x';\gamma)\hat{\mathcal{F}}_\beta(x')\,\rangle$ (eq. (4.131)); if $\mathsf{E}_{x,x'}$ factored as $\varphi_x^*\varphi_{x'}$, the control signal would be product-valued and insensitive to such cross–terms, contradicting the hypothesis. □

4.8.5 Wordwise Prismatic Superposition and Entanglement

Definition 4.331 (Wordwise prismatic superposition at a locus)**.** Fix a locus $\mathfrak{B}_x$, a unitary device word $\mathbf{W}$, and control χ. Let $\mathcal{B}_x^{[\mathbf{W},\chi]}=\{|0\rangle_x^{[\mathbf{W},\chi]},|1\rangle_x^{[\mathbf{W},\chi]},|p\rangle_x^{[\mathbf{W},\chi]},|s\rangle_x^{[\mathbf{W},\chi]}\}$ be the word–rotated orthonormal frame (Definition 4.257, Proposition 4.258, and Remark 4.286). For a nonzero state

$$|\psi\rangle_x^{[\mathbf{W}]}=\sum_{\alpha\in\{0,1,p,s\}}c_\alpha^{[\mathbf{W}]}(x)\,|\alpha\rangle_x^{[\mathbf{W},\chi]},$$

define the *wordwise interference functional* for $\alpha\neq\beta$ by

$$\boxed{\mathsf{I}_{\alpha\beta}^{[\mathbf{W}]}(x;\psi)\;:=\;\Big\langle\mathring{\mathbf{\Psi}}\,\Big|\,\Big(\hat{\mathcal{F}}_\alpha^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^\dagger\hat{\mathcal{F}}_\beta^{[\mathbf{W};\chi\leftarrow\chi]}(x)\,\Big|\,\mathring{\mathbf{\Psi}}\Big\rangle\,\Big(c_\alpha^{[\mathbf{W}]}(x)\Big)^*\,c_\beta^{[\mathbf{W}]}(x),}\tag{4.143}$$

where the word–dressed fields are as in Definitions 4.166 and 4.255 and eq. (4.66). Given a subset $S \subseteq \{0,1,p,s\}$ with $|S| \geq 2$, the state $|\psi\rangle_x^{[\mathbf{W}]}$ is a *(nontrivial) wordwise prismatic superposition across* S iff its projection onto $\mathrm{span}\{|\alpha\rangle_x^{[\mathbf{W},\chi]} : \alpha \in S\}$ has at least two nonzero modal coefficients and there exist $\alpha \neq \beta$ in S with $\mathsf{I}_{\alpha\beta}^{[\mathbf{W}]}(x;\psi) \neq 0$.

Definition 4.332 (Wordwise ontological entanglement between loci)**.** Fix loci $\mathfrak{B}_x, \mathfrak{B}_{x'}$, a word $\mathbf{W}$ and control χ. Let $|\psi_1\rangle_x^{[\mathbf{W}]} = \sum_\alpha c_{1\alpha}^{[\mathbf{W}]} |\alpha\rangle_x^{[\mathbf{W},\chi]}$ and $|\psi_2\rangle_{x'}^{[\mathbf{W}]} = \sum_\beta c_{2\beta}^{[\mathbf{W}]} |\beta\rangle_{x'}^{[\mathbf{W},\chi]}$. For a chosen path $\gamma : x' \to x$ with transporter $\mathcal{U}(x \leftarrow x';\gamma) = \mathcal{P}\exp\!\big(-\int_\gamma \mathcal{A}\big)$ (Definition 4.248 and Section 4.1.4), define the bilinear form

$$\boxed{\mathsf{E}_{x,x'}^{[\mathbf{W}]}(\psi_1,\psi_2) := \sum_{\alpha,\beta} \left\langle \mathring{\mathbf{\Psi}} \,\middle|\, \Big(\hat{\mathcal{F}}_\alpha^{[\mathbf{W};\chi\leftarrow\chi]}(x)\Big)^\dagger \mathcal{U}(x\leftarrow x';\gamma)\, \hat{\mathcal{F}}_\beta^{[\mathbf{W};\chi\leftarrow\chi]}(x') \,\middle|\, \mathring{\mathbf{\Psi}} \right\rangle \big(c_{1\alpha}^{[\mathbf{W}]}\big)^*\, c_{2\beta}^{[\mathbf{W}]}.} \tag{4.144}$$

The Holo–State exhibits *wordwise entanglement* between x and x' iff $\mathsf{E}_{x,x'}^{[\mathbf{W}]}$ does *not* factor as $\varphi_x(\psi_1)^*\,\varphi_{x'}(\psi_2)$ for any linear functionals $\varphi_x, \varphi_{x'}$ on the respective modal fibres. Equivalently, the kernel matrix $\big(\langle(\hat{\mathcal{F}}_\alpha^{[\cdot]}(x))^\dagger \mathcal{U}\, \hat{\mathcal{F}}_\beta^{[\cdot]}(x')\rangle\big)_{\alpha,\beta}$ has modal rank > 1 in $|\mathring{\mathbf{\Psi}}\rangle$ (Section 4.1.2 and eq. (4.66)).

Proposition 4.333 (Word/gauge invariance)**.** *Under endpoint gauge $g \in \mathrm{U}(4)$, $\mathcal{U} \mapsto g(x)\mathcal{U}g(x')^\dagger$ and $\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]} \mapsto g\,\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}$ (Proposition 4.54 and Corollary 4.64). Under a change of word $\mathbf{W} \to \mathbf{W}'$, $\hat{\mathcal{F}}_\alpha^{[\mathbf{W}']}(x) = U_{[\mathbf{W}',\mathbf{W}]}(x)\,\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x)$ with a fibre unitary $U_{[\mathbf{W}',\mathbf{W}]}$ (Proposition 4.284). Hence the predicates in Definitions 4.331 and 4.332 are invariant: $\mathsf{I}_{\alpha\beta}^{[\mathbf{W}]}$ and the factorisation property of $\mathsf{E}_{x,x'}^{[\mathbf{W}]}$ do not depend on gauge or word choice.*

Full proof. Step 1 (Gauge invariance of the basic kernels). Consider the wordwise single–locus kernel $M_{\alpha\beta}^{[\mathbf{W}]}(x) := \omega\big((\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x))^\dagger \hat{\mathcal{F}}_\beta^{[\mathbf{W}]}(x)\big)$ and the bilocal kernel

$$K_{\alpha\beta}^{[\mathbf{W}]}(x,x';\gamma) = \omega\Big((\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x))^\dagger\, \mathcal{U}(x\leftarrow x';\gamma)\, \hat{\mathcal{F}}_\beta^{[\mathbf{W}]}(x')\Big), \qquad \text{(eq. (4.132))}. \tag{4.145}$$

Under endpoint gauge (Proposition 4.54 and Corollary 4.64),

$$\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x) \mapsto g(x)\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x), \qquad \mathcal{U}(x\leftarrow x';\gamma) \mapsto g(x)\,\mathcal{U}(x\leftarrow x';\gamma)\,g(x')^\dagger.$$

Then, algebraically,

$$(\hat{\mathcal{F}}'_\alpha)^\dagger \hat{\mathcal{F}}'_\beta = (\hat{\mathcal{F}}_\alpha)^\dagger g(x)^\dagger g(x) \hat{\mathcal{F}}_\beta = (\hat{\mathcal{F}}_\alpha)^\dagger \hat{\mathcal{F}}_\beta,$$

and similarly

$$(\hat{\mathcal{F}}'_\alpha)^\dagger \mathcal{U}' \hat{\mathcal{F}}'_\beta = (\hat{\mathcal{F}}_\alpha)^\dagger g(x)^\dagger g(x)\, \mathcal{U}\, g(x')^\dagger g(x')\, \hat{\mathcal{F}}_\beta = (\hat{\mathcal{F}}_\alpha)^\dagger \mathcal{U} \hat{\mathcal{F}}_\beta.$$

Thus the operators inside the expectations are unchanged; hence $M^{[\mathbf{W}]}$ and $K^{[\mathbf{W}]}$ are gauge invariant.

Step 2 (Gauge invariance of the predicates). The interference functional $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}(x;\psi)$ multiplies $M^{[\mathbf{W}]}_{\alpha\beta}(x)$ by modal coefficients $c^*_\alpha c_\beta$ (eq. (4.143)); since $M^{[\mathbf{W}]}$ is gauge invariant and the coefficients are numbers associated to a fixed section in the same fibre, $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}$ is gauge invariant. Likewise, the bilinear $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ uses $K^{[\mathbf{W}]}$ (Definition 4.332 and eq. (4.144)); its value and its factorisation/nonfactorisation are preserved under gauge.

Step 3 (Word change as fibrewise unitary equivalence). Let $U_x := U_{[\mathbf{W}',\mathbf{W}]}(x)$ and $U_{x'} := U_{[\mathbf{W}',\mathbf{W}]}(x')$ be the fibre unitaries from Proposition 4.284 so that $\hat{\mathcal{F}}^{[\mathbf{W}']}_\alpha(x) = U_x\,\hat{\mathcal{F}}^{[\mathbf{W}]}_\alpha(x)$. Then

$$M^{[\mathbf{W}']}(x) = U_x^\dagger\, M^{[\mathbf{W}]}(x)\, U_x, \qquad K^{[\mathbf{W}']}(x,x';\gamma) = U_x^\dagger\, K^{[\mathbf{W}]}(x,x';\gamma)\, U_{x'}.$$

(Here we use the functorial/endpoint nature of word evaluation, Proposition 4.284, which ensures that the transporter is left untouched and the endpoint letters are rotated unitarily.)

Step 4 (Word invariance of the predicates). Write the interference scalar as a quadratic form

$$\mathsf{I}^{[\mathbf{W}]}(x;\psi) = c^{[\mathbf{W}]}(x)^\dagger\, M^{[\mathbf{W}]}(x)\, c^{[\mathbf{W}]}(x),$$

with coefficient column $c^{[\mathbf{W}]}(x)$. Under $\mathbf{W} \to \mathbf{W}'$ the same physical section has coefficients $c^{[\mathbf{W}']}(x) = U_x^{-1}\, c^{[\mathbf{W}]}(x)$ in the rotated basis. Then

$$\begin{aligned}
\mathsf{I}^{[\mathbf{W}']}(x;\psi) &= \left(c^{[\mathbf{W}']}\right)^\dagger M^{[\mathbf{W}']}\, c^{[\mathbf{W}']} \\
&= \left(c^{[\mathbf{W}]}\right)^\dagger U_x^{-\dagger}\, (U_x^\dagger M^{[\mathbf{W}]} U_x)\, U_x^{-1}\, c^{[\mathbf{W}]} \\
&= \left(c^{[\mathbf{W}]}\right)^\dagger M^{[\mathbf{W}]}\, c^{[\mathbf{W}]} \\
&= \mathsf{I}^{[\mathbf{W}]}(x;\psi). \qquad (4.146)
\end{aligned}$$

Hence the presence/absence of prismatic superposition (Definition 4.331) is word invariant.

For the entanglement bilinear, let $c_1^{[\mathbf{W}]}(x), c_2^{[\mathbf{W}]}(x')$ be coefficient vectors at x, x'. Then

$$\mathsf{E}^{[\mathbf{W}]}_{x,x'}(\psi_1,\psi_2) = \left(c_1^{[\mathbf{W}]}(x)\right)^\dagger K^{[\mathbf{W}]}(x,x';\gamma)\, c_2^{[\mathbf{W}]}(x').$$

Under the word change, $c_1^{[\mathbf{W}']} = U_x^{-1} c_1^{[\mathbf{W}]}$, $c_2^{[\mathbf{W}']} = U_{x'}^{-1} c_2^{[\mathbf{W}]}$, and $K^{[\mathbf{W}']} = U_x^\dagger K^{[\mathbf{W}]} U_{x'}$. Therefore

$$\mathsf{E}^{[\mathbf{W}']}_{x,x'}(\psi_1,\psi_2) = \left(c_1^{[\mathbf{W}]}\right)^\dagger K^{[\mathbf{W}]} c_2^{[\mathbf{W}]} = \mathsf{E}^{[\mathbf{W}]}_{x,x'}(\psi_1,\psi_2).$$

In particular, factorisation of E is preserved: if $\mathsf{E}^{[\mathbf{W}]}_{x,x'}(\psi_1,\psi_2) = \varphi_x(\psi_1)^*\,\varphi_{x'}(\psi_2)$, then setting $\varphi'_x := \varphi_x \circ U_x{}^{-1}$ and $\varphi'_{x'} := \varphi_{x'} \circ U_{x'}{}^{-1}$ gives $\mathsf{E}^{[\mathbf{W}']}_{x,x'}(\psi_1,\psi_2) = \varphi'_x(\psi_1)^*\,\varphi'_{x'}(\psi_2)$; conversely, invertibility of $U_x, U_{x'}$ shows nonfactorisation cannot be created or destroyed by a word change.

Step 5 (Conclusion). Both the interference functional $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}$ and the factorisation property of $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ are invariant under endpoint gauge (Proposition 4.54 and Corollary 4.64) and under word changes (Proposition 4.284). Therefore the predicates in Definitions 4.331 and 4.332 are well defined, independent of gauge and of the chosen endogenous word. □

Proposition 4.334 (Wordwise parasymmetric test on the Twofold slice)**.** *On the Twofold subspace* $S_x^{[\mathbf{W}]} = \mathrm{span}\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\}$ *(Definition 4.304), let* $P_{\mathrm{para}}^{[\mathbf{W}]}$ *and* $P_{\mathrm{antipara}}^{[\mathbf{W}]}$ *be the parasymmetric/anti–parasymmetric effects (with* $P_{\mathrm{para}}^{[\mathbf{W}]} + P_{\mathrm{antipara}}^{[\mathbf{W}]} = P_{(0,1)}^{[\mathbf{W}]}$*). For* $|\psi\rangle_x^{[\mathbf{W}]} = c_0^{[\mathbf{W}]}|0\rangle_x^{[\mathbf{W},\chi]} + c_1^{[\mathbf{W}]}|1\rangle_x^{[\mathbf{W},\chi]}$*,*

$$\boxed{\left\langle P_{\mathrm{para}}^{[\mathbf{W}]} \right\rangle_\psi = \tfrac{1}{2}\Big(\langle (\hat{\mathcal{F}}_0^{[\cdot]})^\dagger \hat{\mathcal{F}}_0^{[\cdot]} \rangle \left| c_0^{[\mathbf{W}]} \right|^2 + \langle (\hat{\mathcal{F}}_1^{[\cdot]})^\dagger \hat{\mathcal{F}}_1^{[\cdot]} \rangle \left| c_1^{[\mathbf{W}]} \right|^2 + 2\ \mathrm{Re}\ \mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi) \Big),} \tag{4.147}$$

so $|\psi\rangle_x^{[\mathbf{W}]}$ *is a nontrivial wordwise prismatic superposition across* $\{0,1\}$ *iff the parasymmetric/anti–parasymmetric pair yields a phase–sensitive split* ($\mathsf{I}_{01}^{[\mathbf{W}]} \neq 0$*).*

Full proof. Step 1 (Local Twofold coefficients and induced quadratic form). In the wordwise setting, the coincident–limit inner product on the Twofold slice is induced by the local wordwise kernel $M_{\alpha\beta}^{[\mathbf{W}]}(x) := \omega\Big((\hat{\mathcal{F}}_\alpha^{[\mathbf{W}]}(x))^\dagger \hat{\mathcal{F}}_\beta^{[\mathbf{W}]}(x)\Big)$ (Section 4.6, Definition 4.9). For $|\psi\rangle_x^{[\mathbf{W}]} = c_0^{[\mathbf{W}]}|0\rangle_x^{[\mathbf{W},\chi]} + c_1^{[\mathbf{W}]}|1\rangle_x^{[\mathbf{W},\chi]}$ the valuation of any Twofold effect E is a quadratic form in the coefficients, built from matrix elements of E and $M^{[\mathbf{W}]}$.

Step 2 (Parasymmetric/anti–parasymmetric effects on the Twofold). By definition, $P_{\mathrm{para}}^{[\mathbf{W}]}$ and $P_{\mathrm{antipara}}^{[\mathbf{W}]}$ are the $(\pm)$ effects associated with the 0/1 interference test on $S_x^{[\mathbf{W}]}$ ("Hadamard–like" split), satisfying $P_{\mathrm{para}}^{[\mathbf{W}]} + P_{\mathrm{antipara}}^{[\mathbf{W}]} = P_{(0,1)}^{[\mathbf{W}]}$, where $P_{(0,1)}^{[\mathbf{W}]}$ is the identity effect on the Twofold block. Consequently,

$$\left\langle P_{\mathrm{para}}^{[\mathbf{W}]} \right\rangle_\psi = \tfrac{1}{2}\Big(\left\langle P_{(0,1)}^{[\mathbf{W}]} \right\rangle_\psi + \left\langle X^{[\mathbf{W}]} \right\rangle_\psi \Big), \qquad \left\langle P_{\mathrm{antipara}}^{[\mathbf{W}]} \right\rangle_\psi = \tfrac{1}{2}\Big(\left\langle P_{(0,1)}^{[\mathbf{W}]} \right\rangle_\psi - \left\langle X^{[\mathbf{W}]} \right\rangle_\psi \Big), \tag{4.148}$$

where $X^{[\mathbf{W}]}$ is the off–diagonal "exchange" contribution that carries the phase sensitivity.

Step 3 (Evaluate the diagonal and off–diagonal parts). The diagonal (block–identity) valuation is

$$\left\langle P_{(0,1)}^{[\mathbf{W}]} \right\rangle_\psi = \left\langle (\hat{\mathcal{F}}_0^{[\cdot]})^\dagger \hat{\mathcal{F}}_0^{[\cdot]} \right\rangle \left| c_0^{[\mathbf{W}]} \right|^2 + \left\langle (\hat{\mathcal{F}}_1^{[\cdot]})^\dagger \hat{\mathcal{F}}_1^{[\cdot]} \right\rangle \left| c_1^{[\mathbf{W}]} \right|^2,$$

since the cross–terms are absent in the block identity. For the off–diagonal exchange piece, Hermiticity of $M^{[\mathbf{W}]}$ gives $M_{10}^{[\mathbf{W}]}(x) = \overline{M_{01}^{[\mathbf{W}]}(x)}$, and therefore

$$\left\langle X^{[\mathbf{W}]} \right\rangle_\psi = c_0^{[\mathbf{W}]*} c_1^{[\mathbf{W}]}\, M_{01}^{[\mathbf{W}]}(x) + c_1^{[\mathbf{W}]*} c_0^{[\mathbf{W}]}\, M_{10}^{[\mathbf{W}]}(x) = 2\ \mathrm{Re}\Big(c_0^{[\mathbf{W}]*} c_1^{[\mathbf{W}]}\, M_{01}^{[\mathbf{W}]}(x) \Big).$$

By the definition of the wordwise interference functional (Definition 4.331 and eq. (4.143)), $\mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi) := M_{01}^{[\mathbf{W}]}(x)\, c_0^{[\mathbf{W}]*} c_1^{[\mathbf{W}]}$. Hence $\left\langle X^{[\mathbf{W}]} \right\rangle_\psi = 2\ \mathrm{Re}\ \mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi)$.

Step 4 (Assemble and conclude). Plugging the diagonal and off–diagonal evaluations into (4.148) yields (4.147). Moreover,

$$\left\langle P_{\mathrm{para}}^{[\mathbf{W}]} \right\rangle_\psi - \left\langle P_{\mathrm{antipara}}^{[\mathbf{W}]} \right\rangle_\psi = \left\langle X^{[\mathbf{W}]} \right\rangle_\psi = 2\ \mathrm{Re}\ \mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi).$$

Therefore the parasymmetric/anti–parasymmetric pair exhibits a nontrivial, phase–sensitive split iff $\mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi) \neq 0$, which is exactly the predicate for a nontrivial wordwise prismatic superposition across $\{0,1\}$ in Definition 4.331. This completes the proof. □

Proposition 4.335 (Reduction to standard Hilbert–space notions in the Twofold regime (wordwise))**.** *If the wordwise Twofold sector $S_x^{[\mathbf{W}]}$ is dynamically protected and off–block couplings are negligible (Propositions 4.262 and 4.306), then there exists an isometry $U^{[\mathbf{W}]} : \mathbb{C}^2 \hookrightarrow \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ with $U^{[\mathbf{W}]}\,|0\rangle = |0\rangle_x^{[\mathbf{W},\chi]}$, $U^{[\mathbf{W}]}\,|1\rangle = |1\rangle_x^{[\mathbf{W},\chi]}$ (Definition 4.305). Consequently:*

(i) $|\psi\rangle_x^{[\mathbf{W}]}$ is a wordwise prismatic superposition across $\{0,1\}$ iff $(U^{[\mathbf{W}]})^\dagger|\psi\rangle_x^{[\mathbf{W}]}$ is a nontrivial linear combination in $\mathbb{C}^2$.

(ii) Wordwise entanglement between x, x' per Definition 4.332 holds iff the induced state on $\mathbb{C}^2 \otimes \mathbb{C}^2$ is entangled in the standard sense (after compression by $(U^{[\mathbf{W}]})^\dagger \otimes (U^{[\mathbf{W}]})^\dagger$); see also Corollary 4.308.

Full proof. Step 0 (Set–up and protection). Let $S_x^{[\mathbf{W}]} = \mathrm{span}\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\}$ be invariant under the admissible local generators (dynamic protection), and let $P^{[\mathbf{W}]}$ be the orthogonal projector onto $S_x^{[\mathbf{W}]}$. Off–block couplings are negligible in the sense of Proposition 4.262, so that compressed dynamics on $S_x^{[\mathbf{W}]}$ closes up to controlled $O(\varepsilon)$ errors.

Step 1 (Isometry $U^{[\mathbf{W}]}$). Define $U^{[\mathbf{W}]} : \mathbb{C}^2 \to \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ by $U^{[\mathbf{W}]}\,|0\rangle = |0\rangle_x^{[\mathbf{W},\chi]}$, $U^{[\mathbf{W}]}\,|1\rangle = |1\rangle_x^{[\mathbf{W},\chi]}$ and extend linearly (Definition 4.305). Since $\{|0\rangle_x^{[\mathbf{W},\chi]}, |1\rangle_x^{[\mathbf{W},\chi]}\}$ is orthonormal in the fibre metric (induced from the correlator; cf. Section 4.6 and eq. (4.92)), one has, for all $\phi, \psi \in \mathbb{C}^2$, $\langle \phi, \psi\rangle_{\mathbb{C}^2} = \langle U^{[\mathbf{W}]}\phi,\, U^{[\mathbf{W}]}\psi\rangle_x$. Hence $U^{[\mathbf{W}]}$ is an isometry with image $S_x^{[\mathbf{W}]}$ (Proposition 4.306).

Step 2 (Superposition equivalence). Write $|\psi\rangle_x^{[\mathbf{W}]} = c_0^{[\mathbf{W}]}|0\rangle_x^{[\mathbf{W},\chi]} + c_1^{[\mathbf{W}]}|1\rangle_x^{[\mathbf{W},\chi]}$. Then $(U^{[\mathbf{W}]})^\dagger|\psi\rangle_x^{[\mathbf{W}]} = c_0^{[\mathbf{W}]}\,|0\rangle + c_1^{[\mathbf{W}]}\,|1\rangle \in \mathbb{C}^2$. If $(U^{[\mathbf{W}]})^\dagger|\psi\rangle$ is a nontrivial linear combination in $\mathbb{C}^2$ (both coefficients not simultaneously zero), the same coordinates describe $|\psi\rangle_x^{[\mathbf{W}]}$ in the fibre, so by the wordwise parasymmetric test the pair $P_{\mathrm{para}}^{[\mathbf{W}]}, P_{\mathrm{antipara}}^{[\mathbf{W}]}$ exhibits a phase–sensitive split precisely controlled by the interference term (Proposition 4.334). Conversely, if $|\psi\rangle_x^{[\mathbf{W}]}$ is a wordwise prismatic superposition across $\{0,1\}$, then $\mathsf{I}_{01}^{[\mathbf{W}]}(x;\psi) \neq 0$ for some choice of parasymmetric phase (word/basis) and therefore $c_0^{[\mathbf{W}]}, c_1^{[\mathbf{W}]}$ are not both zero; hence $(U^{[\mathbf{W}]})^\dagger|\psi\rangle$ is a nontrivial linear combination in $\mathbb{C}^2$. Word/gauge invariance of the predicate guarantees independence of the chosen word/basis (Proposition 4.333). This proves (i).

Step 3 (Entanglement equivalence). Let x, x' be two loci with protected Twofold sectors $S_x^{[\mathbf{W}]}, S_{x'}^{[\mathbf{W}]}$ and corresponding isometries $U_x^{[\mathbf{W}]}, U_{x'}^{[\mathbf{W}]}$. For test vectors $\psi_1 \in S_x^{[\mathbf{W}]}$, $\psi_2 \in S_{x'}^{[\mathbf{W}]}$, the wordwise entanglement bilinear $\mathsf{E}_{x,x'}^{[\mathbf{W}]}(\psi_1, \psi_2)$ is computed from the bilocal kernel (Definition 4.332 and eq. (4.144)). Compressing by $(U_x^{[\mathbf{W}]})^\dagger \otimes (U_{x'}^{[\mathbf{W}]})^\dagger$ gives a bilinear on $\mathbb{C}^2 \otimes \mathbb{C}^2$ whose values agree with the original ones, because $E \mapsto UEU^\dagger$ is a unital $*$–monomorphism of effect algebras on the protected block and the transport is compatible with compression (dynamic protection; Proposition 4.306). Therefore the factorisation property of $\mathsf{E}_{x,x'}^{[\mathbf{W}]}$ (product vs. nonproduct) holds iff the induced two–qubit state on $\mathbb{C}^2 \otimes \mathbb{C}^2$ is separable vs. entangled in the standard sense. This establishes (ii). The multi–site extension yielding registers follows from the same compression argument and the mixing bounds in Proposition 4.262, as summarised in Corollary 4.308.

Step 4 (Effect of small off–block couplings). If off–block terms are small but nonzero, Proposition 4.262 provides Duhamel–type bounds showing that leakage outside $S_x^{[\mathbf{W}]}$ is $O(\varepsilon t)$ and the compressed dynamics deviates from an exact SU(2) evolution by $O(\varepsilon t)$. The

conclusions of (i)–(ii) then hold to first order in ε over the control timescale, with errors controlled by those bounds.

Hence the protected wordwise Twofold sector realises the standard qubit notions by the isometry $U^{[\mathbf{W}]}$, and superposition/entanglement reduce to their usual Hilbert–space counterparts under compression. □

Remark 4.336 (Compliance–controlled regimes)**.** The holosymmetric compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178) bounds departures from the ideal superposition/entanglement picture: η controls two–step ps/sp leakage, ζ controls diagonal pinching stability, and Δ bounds visibility/lensing drifts in readout. The inequalities of Proposition 4.181 thus certify when wordwise Twofold superpositions behave qubit–like and when non–qubit Fourfold effects must be expected.

Lemma 4.337 (Wordwise holosymmetric dominance)**.** *In a holosymmetric interferometric test (Section 4.7.3), a phase–sensitive local signal implies the existence of $\alpha \neq \beta$ with $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}(x;\psi) \neq 0$ as in Definition 4.331; a nonseparable bilocal signal implies that the bilinear form $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ of Definition 4.332 does not factor.*

Sketch. Write the holosymmetric readout as a Born valuation of a word–evaluated s–channel operator (eqs. (4.122) and (4.123)). Phase sensitivity under a control Hadamard requires nonzero off–diagonal modal overlaps in that operator, forcing $\langle(\hat{\mathcal{F}}^{[\cdot]}_{\alpha})^{\dagger}\hat{\mathcal{F}}^{[\cdot]}_{\beta}\rangle \neq 0$, hence $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta} \neq 0$. For the bilocal case, a nonseparable signal entails nontrivial cross–modal entries in the kernel $\langle(\hat{\mathcal{F}}^{[\cdot]}_{\alpha}(x))^{\dagger}\mathcal{U}\,\hat{\mathcal{F}}^{[\cdot]}_{\beta}(x')\rangle$, which would vanish if $\mathsf{E}^{[\mathbf{W}]}_{x,x'}$ factored; cf. Definition 4.332. □

Superposition (plain-language view, formalised). Superposition means a single system *coherently* occupies more than one compatible possibility at once, with a phase relation that can generate interference. In the qubit caricature this is $\alpha\,|0\rangle + \beta\,|1\rangle$. In the present framework, the same idea is expressed on the Fourfold modal fibre $\{|0\rangle, |1\rangle, |p\rangle, |s\rangle\}$ (Definition 4.273) by requiring that the state has support on at least two modal directions *and* a nonzero interference functional between them. Exogenously this is captured by Definition 4.325; endogenously (wordwise) it is Definition 4.331, where coherence shows up through the word–evaluated interference term $\mathsf{I}^{[\mathbf{W}]}_{\alpha\beta}(x;\psi)$ (eq. (4.143)). Intuitively: superposition is "coexistence with a phase''—and the phase is what powers interference in parasymmetric tests (Proposition 4.334).

Entanglement (plain-language view, formalised). Entanglement is superposition *spread across loci* in a way that cannot be pulled apart into independent local descriptions. In textbook language this is a non-product state on $\mathbb{C}^2 \otimes \mathbb{C}^2$; here it means the inter–locus correlator does *not* factor. Exogenously this is Definition 4.326; endogenously it is Definition 4.332, where non-factorisation of the bilinear form $\mathsf{E}^{[\mathbf{W}]}_{x,x'}(\psi_1, \psi_2)$ (eq. (4.144))—built from word–dressed channels and the transporter $\mathcal{U}$ (Definition 4.248)—certifies entanglement. Operationally, non-factorisation means measurement statistics at one locus correlate with those at another beyond any classical explanation.

Two clarifications from the holomodal framework. First, the parasymmetric/holosymmetric directions $|p\rangle, |s\rangle$ are *independent* modal directions, not mere qubit superpositions; superposition and entanglement can thus involve genuinely Fourfold structure, not only the Twofold slice (Remark 4.269 and Proposition 4.281). Second, geometry matters: wordwise holonomy in the s–channel (loop operator and signal; Section 4.7.3 and eqs. (4.122) and (4.123)) and the compliance vector $\mathfrak{K} = (\Delta, \eta, \zeta)$ (Definition 4.178) quantify how much interference survives and how cleanly non-factorisable correlations can be read (Proposition 4.181). In short, coherence (superposition) and nonlocal correlations (entanglement) are not just kinematic labels but *measurable, geometry–aware* features of the holomodal setup.

4.9 Operator-Theoretic Intrinsic Distances

Building upon IQR (Definition 1.25), the emergent quantum configuration space $\mathcal{X}_q$ (Proposition 4.625 and Section 4.19.4), the fibred $\hat{\Omega}$–Continuum (Definition 4.617), and the Quantum Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27), we now formalize operator-theoretic measures of emergent distance and time between PQS loci. These quantities are relational and derive from the intrinsic quantum–geometric and correlational structure as perceived by $|\mathring{\mathbf{\Psi}}\rangle$.

We introduce three principal components of emergent distance between a PQS $\mathfrak{B}_x$ (at $x \in \mathcal{X}_q$) and another $\mathfrak{B}_{x'}$. Each furnishes one axis of an orthogonal, operator-derived chronogeometric profile.

4.9.1 Correlator-Based Distance

Intuitively, $d_{\mathrm{corr}}(x, x')$ quantifies *operator-algebraic distinguishability* between the modal structures at $\mathfrak{B}_x$ and $\mathfrak{B}_{x'}$, as mediated by the Fourfold Inter-Modal Correlator $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})$ (see Section 4.1.2) and evaluated in the Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ (Definition 1.27). Small values signal high coherence/similarity; large values signal low coherence/dissimilarity. [230, 241]

To make this precise, fix *reference modal vectors* $|\psi_1\rangle_x, |\psi_2\rangle_{x'}$ in the four-mode fibres $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)} = \mathrm{span}\{|0\rangle_x, |1\rangle_x, |p\rangle_x, |s\rangle_x\}$ and $\mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})}$, and write the scalar correlator amplitude

$$\mathsf{G}(x, x'; \psi_1, \psi_2) \;:=\; \Big\langle \mathring{\mathbf{\Psi}} \Big|\, \hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'}) \big[\psi_1^*, \psi_2\big] \,\Big|\, \mathring{\mathbf{\Psi}} \Big\rangle,$$

where $\hat{G}_\Lambda(\mathfrak{B}_x, \mathfrak{B}_{x'})[\psi_1^*, \psi_2]$ is the bilinear evaluation of the (already defined) Fourfold correlator on the chosen test vectors (cf. Section 4.1.2). [382, 383, 82] Define the natural normalizations by the coincident limits

$$N(\psi_1, x) \;:=\; \Big(\mathsf{G}(x, x; \psi_1, \psi_1)\Big)^{1/2}, \qquad N(\psi_2, x') \;:=\; \Big(\mathsf{G}(x', x'; \psi_2, \psi_2)\Big)^{1/2}.$$

[82, 384]

Definition 4.338 (Correlator-Based Distance)**.** With the notation above, the *correlator-based similarity* is

$$C(x, x'; \psi_1, \psi_2) \;:=\; \frac{\big|\mathsf{G}(x, x'; \psi_1, \psi_2)\big|}{N(\psi_1, x)\, N(\psi_2, x')} \;\in\; [0, 1],$$

and the *correlator-based distance* is

$$d_{\mathrm{corr}}(x,x';\psi_1,\psi_2) \;:=\; \sqrt{1-C(x,x';\psi_1,\psi_2)} \;\in\; [0,1]. \tag{4.149}$$

[359, 385, 386, 387, 50, 388]

Discussion. (i) $d_{\mathrm{corr}}=0$ iff the normalized correlator attains unit modulus (maximal similarity under the chosen probes); $d_{\mathrm{corr}}=1$ iff the evaluated overlap vanishes. (ii) The construction is invariant under admissible reindexings and the duality involution (Proposition 1.8), and under phase rescalings of the test vectors. (iii) If desired, one may remove dependence on probes by taking an extremum over admissible $|\psi_1\rangle_x, |\psi_2\rangle_{x'}$ within a fixed class; we keep the reference-dependent form here to emphasize operational context and avoid additional optimization hypotheses. This encapsulates, without recourse to classical coordinates, the intrinsic coherence/overlap of the full Fourfold modal content across loci as registered by $|\mathring{\mathbf{\Psi}}\rangle$. In the Twofold (duality-collapse) regime (Definition 4.87), (4.149) reduces to the standard qubit overlap–to–distance transformation on the $\{0,1\}$ slice (cf. Proposition 4.328). [287, 359]

4.9.2 Wordwise Correlator-Based Distance (Holosymmetric Realization)

Fix admissible device words $\mathbf{W}_1$ at x and $\mathbf{W}_2$ at x' with RR elements $\mathsf{W}_{1,\chi\leftarrow\chi}(x)$ and $\mathsf{W}_{2,\chi'\leftarrow\chi'}(x')$, acting on the modal fibres as in the wordwise calculus (cf. Sections 4.5 and 4.6.2). For any reference modal vectors $|\psi_1\rangle_x \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_x)}$ and $|\psi_2\rangle_{x'} \in \mathcal{H}_{\mathrm{mod}}^{(\mathfrak{B}_{x'})}$, define their *word-rotated* representatives

$$|\psi_1\rangle_x^{[\mathbf{W}_1,\chi]} := \mathsf{W}_{1,\chi\leftarrow\chi}(x)\,|\psi_1\rangle_x, \qquad |\psi_2\rangle_{x'}^{[\mathbf{W}_2,\chi']} := \mathsf{W}_{2,\chi'\leftarrow\chi'}(x')\,|\psi_2\rangle_{x'}.$$

The *wordwise scalar correlator amplitude* is

$$\mathsf{G}^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2) := \Big\langle \mathring{\mathbf{\Psi}}\Big|\, \hat{G}_\Lambda(\mathfrak{B}_x,\mathfrak{B}_{x'})\Big[\big(\psi_1^{[\mathbf{W}_1,\chi]}\big)^*,\ \psi_2^{[\mathbf{W}_2,\chi']}\Big]\,\Big|\mathring{\mathbf{\Psi}}\Big\rangle, \tag{4.150}$$

where the bilinear evaluation of the Fourfold correlator is as in Section 4.1.2 but applied only to word-rotated test vectors; the Holo-State $|\mathring{\mathbf{\Psi}}\rangle$ is as in Definition 1.27. [230, 241, 382, 383, 82]

Wordwise normalizations. Using the coincident-limit inner product from Section 4.6, set

$$N^{[\mathbf{W}_1]}(\psi_1,x) := \Big(\,\mathsf{G}^{[\mathbf{W}_1,\mathbf{W}_1]}(x,x;\psi_1,\psi_1)\,\Big)^{1/2}, \quad N^{[\mathbf{W}_2]}(\psi_2,x') := \Big(\,\mathsf{G}^{[\mathbf{W}_2,\mathbf{W}_2]}(x',x';\psi_2,\psi_2)\,\Big)^{1/2}. \tag{4.151}$$

These coincide with the exogenous normalizations when $\mathbf{W}_1=\mathbf{W}_2=\mathbf{1}$ by unitary invariance of the fibre metric and the endogenous evaluation map. [82, 384]

Definition 4.339 (Wordwise Correlator-Based Distance)**.** With the notation above, the *wordwise correlator-based similarity* is

$$C^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2) := \frac{\big|\mathsf{G}^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2)\big|}{N^{[\mathbf{W}_1]}(\psi_1,x)\,N^{[\mathbf{W}_2]}(\psi_2,x')} \;\in [0,1], \tag{4.152}$$

and the *wordwise correlator-based distance* is

$$d_{\mathrm{corr}}^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2) := \sqrt{1-C^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2)} \;\in [0,1]. \tag{4.153}$$

By Cauchy–Schwarz in the fibre inner product from Section 4.6, $C^{[\mathbf{W}_1,\mathbf{W}_2]} \in [0,1]$ and hence (4.153) is well-defined. [359, 385, 386, 387, 50, 388]

Proposition 4.340 (Word/Gauge Invariance and Equivalence to Exogenous Form)**.** *For any admissible words* $\mathbf{W}_1, \mathbf{W}_2$ *and endpoint gauges,*

$$C^{[\mathbf{W}_1,\mathbf{W}_2]}(x,x';\psi_1,\psi_2) = C(x,x';\psi_1,\psi_2), \qquad d^{[\mathbf{W}_1,\mathbf{W}_2]}_{\mathrm{corr}}(x,x';\psi_1,\psi_2) = d_{\mathrm{corr}}(x,x';\psi_1,\psi_2),$$

where C, d_{corr} *are as in Definition 4.338.* Sketch. *Word-rotation multiplies both probes by local unitaries* $\mathsf{W}_{1,\chi\leftarrow\chi}(x)$ *and* $\mathsf{W}_{2,\chi'\leftarrow\chi'}(x')$*; by unitary invariance of the fibre inner product and the bilinear evaluation of* $\hat{G}_\Lambda$ *(cf. Section 4.5), the numerator and denominators in* (4.152) *transform covariantly and their ratio is invariant. Endpoint gauges act similarly on both legs; adjoint reciprocity of the correlator ensures modulus invariance.*
